With the growth of the lumber industry came the grainer, a distinctly Michigan type of salt-making apparatus. This is a tank 18 to 24 in. deep, 12 to 18 ft. wide and 100 to 120 ft. long. In this are submerged a number of pipes through which passes steam (or hot condensed water from previous grainers). The brine does not boil, but merely evaporates slowly. The size of grain depends on the rate of evaporation, which in turn depends on the temperature of the brine, as the coils are heated by live steam, exhaust steam, or condensed water. The salt grows on the surface as floating aggregates of hopper-shaped crystals. These fall to the bottom and are raked out by hand, or more often by mechanical rakes actuated by hydraulic cylinders. The grainers are made of wood, steel or concrete.

In 1887 the first vacuum pan was introduced into Michigan, and there are now a number of plants using single or multiple effect vacuum pans. This process gives a fine, uniform, compact grain, very well suited for table purposes. The coarse and less compact grain-salt occludes mother-liquor and is less pure.

THE ALBERGER PROCESS OF SALT MAKING

Michigan has the only plant in this country using the Alberger process. In this process the brine is heated in steps to about 350 deg. F., at which point the solubility of calcium sulphate is very low. The brine is then led through cylinders filled with stones, where the gypsum is deposited, the supersaturated solution being seeded by crystals adhering to the stones; and then the brine is led to the "evaporators." These are nothing but cylinders with an opening near the top where the superheated brine is allowed to escape. The flash or self-evaporation which takes place when the pressure is relieved causes the formation of seed crystals. The hot brine with these seed crystals is blown out into large shallow pans. Surface evaporation causes the crystals to grow till they fall to the bottom and are raked to a well, whence they pass to a centri-

fuge. The brine overflowing from the pans is returned to the heaters. This process gives a very open and porous grain, but far finer than the grainer salt. It is almost entirely used for table and dairy purposes.

No account of the Michigan salt industry is complete without mention of the Manistee Iron Works. They introduced the vacuum pan into the salt industry; and Manistee pans are found not only in most of the vacuum pan plants of the State, but in many salt plants throughout the country.

Table I gives a list of some Michigan salt plants, and Table II gives the Michigan salt production as compared with that of the total in the United States for the years 1914 to 1917.

BROMINE AND CALCIUM CHLORIDE

The brines of the Saginaw Valley contain many impurities, chiefly bromides and calcium and magnesium salts. The Dow Chemical Co. of Midland has for years been by far the largest producer of bromine in the United States. The brine is electrolyzed to give a gas consisting of chlorine and bromine, and this gas is used to displace the bromine from the brine. Calcium chloride is made by the Saginaw Chemical Co. Bitters discarded from salt grainers are further concentrated, which throws out much sodium chloride. The solubility of sodium chloride decreases rapidly as the concentration of calcium chloride increases. The remaining mixture of calcium and magnesium chlorides is concentrated till it solidifies when run into drums. Large quantities of calcium chloride are also obtained as a by-product in the Solvay process.

ALKALIS, ACIDS AND HEAVY CHEMICALS

Because of the salt deposits, Michigan has an enormous alkali industry. In the Detroit district are the Solvay Process Co., the Pennsylvania Salt Manufacturing Co. and the Michigan Alkali Co. The Dow Chemical Co. at Midland also produces alkali. The Solvay Process Co. and the Michigan Alkali Co. use the Solvay process; the others make electrolytic caustic. The Pennsylvania Salt Manufacturing Co. uses the Gibbs cell; the Dow Chemical Co. a cell of its own. Sulphuric and nitric acids are made by the Detroit Chemical Works, which also makes alum. The electrolytic plants of course make either chlorine or bleach according to the demands; though the Dow Chemical

Co. uses most of its chlorine in various organic products.

The North American Chemical Co. at Saginaw makes electrolytic chlorate.

POTASH

Michigan's contribution to the potash situation has been from two sources—wood ashes and beet sugar waste waters. This latter is mentioned in connection with the sugar industry. In the hardwood districts there are reported about 25 small producers of potash salts from wood ashes. The ashes are packed in shallow tubs, leached, and the resulting solution concentrated till it solidifies. The product is mainly carbonate; if lime is added with the ashes it is largely hydroxide. Of some 32,500 tons of K_2O reported as produced in the United States in 1917, wood ashes (in which Michigan has 25 out of 49 producers) are credited with furnishing 621 tons, and beet sugar waste waters (where Michigan has one out of 5 producers) with 370 tons.

IRON AND STEEL

Though Michigan is the second largest producer of iron ore in the United States, the iron actually smelted is very small in amount. The Marquette, Gogebic and Menominee ranges, lying mainly in Michigan, produce about 25 per cent of the country's total output of ore and about 30 per cent of the output of the Superior district. Michigan is only about seventh in pig iron production, having only 14 blast-furnaces. The State has no steel plants, though there are steel foundries having one or two open-hearth furnaces apiece. Most of the blast-furnaces are connected with the hardwood distillation industry, and serve as an outlet for the charcoal. Detroit has three furnaces—two at the plant of the Detroit Iron and Steel Co. and one at the plant of the Detroit Furnace Co.

Table III gives a list of the Michigan blast-furnaces operating in 1916.

NON-FERROUS METALS

Michigan has for some time been the country's third largest producer of copper. Other than this no non-ferrous metals are smelted in appreciable amounts. The

COKE

The State possesses two coke oven plants, neither primarily connected with the iron industry. The ovens are at the plants of the Solvay Process Co. and the Michigan Alkali Co.; and both plants use the ovens as a source of ammonia. The coke goes to the blast-furnaces in Detroit, to the lime kilns of the alkali process, or is sold for domestic consumption.

The Solvay Process Co. obtains its ammonia from the Semet-Solvay Co., which operates 175 Semet-Solvay ovens. The latest bank of these are equipped to burn producer gas, as under a heating value specification so much gas can be sold to the city of Detroit that not enough remains to heat the ovens. All the newer ovens are regenerative, in contrast with the older design of the Semet-Solvay oven, which was recuperative.

The Michigan Alkali Co. has 30 United-Otto ovens.

COAL AND PEAT

A large area in the central part of the State contains coal. The deposits have been worked more or less since 1835, but the industry did not develop till 1897. Recently the production has been about 1,000,000 tons per year. The coal is bituminous, dry and non-coking, and generally of a lower grade than the Eastern coals with which it has to compete. In 1916 there were reported 22 mines.

The State has very extensive deposits of peat—in fact, over the whole State peat bogs are common. Numerous attempts have been made to work these deposits, and much good money has been wasted. Without exception the plants have all been failures. The peat remains, however, as a possible fuel when either coal is so high as to make it available, or satisfactory methods are found for its utilization.

BEET SUGAR

Michigan is almost the home of the beet sugar industry in the United States. Certainly the industry took hold here in a very healthy manner and mills were built more rapidly in Michigan than in any other State. As the value of irrigated lands and the favorable climate of the Western States began to be appreciated, Colorado and California passed Michigan, but Michigan still remains one of the principal producers of beet sugar. Table IV is taken from the U. S. Department of Agriculture Yearbook, 1917.

The drop from third to fourth place in 1916 was due not only to the falling off in the Michigan production, but to the rapid rise of Utah as a beet sugar State.

The beet mills in the State are shown in Table V.

TABLE IV—BEET SUGAR INDUSTRY IN MICHIGAN

Year	Michigan's Rank	No. Factories	Campaign Days	Tons Sugar Made	Acres Harvested	Tons Beets per Acre	Tons Beets Worked	Price per Ton	Per Cent Sugar in Beets	Purity	Per Cent Sugar Recorded	Per Cent of Total Sugar Harvested	Per Cent of Total	Michigan Production per Cent of U. S. Total

Owosso Sugar Co.	Owosso	1903	1,200
Continental Sugar Co.	Blissfield	1905	868

This shows the State to have a total capacity of 15,000 tons of beets per day. With a campaign of 70 days this calls for a little over 1,000,000 tons of beets for the campaign. This means that the industry was working to capacity in 1915; but, with a campaign of 50 days, only about two-thirds capacity in 1916 and 1917.

Many mills run the Steffens process, and many dry their pulp for the manufacture of cattle feed. Since the mills are all older than most Western mills, the newer equipment (such as labor-saving filters, etc.) found so frequently in the Western mills has not yet been generally introduced.

Two interesting developments in connection with the sugar industry are the plants of the Michigan Chemical Co., at Bay City, which ferments beet molasses to alcohol; and the plant of the Columbia Sugar Co. which has been evaporating its Steffens waste water for the recovery of potash.

WOOD DISTILLATION

Michigan ranks in the first two or three States in the quantity of wood distilled. This is largely centered in the Upper Peninsula, though there are some wood distillation plants in the Lower Peninsula. E. I. du Pont de Nemours & Co. has plants at Bay City and Braying. The Cleveland-Cliffs Iron Co., the Charcoal Iron Co. of America and the Lake Superior Iron & Chemical Co. all operate plants in the Upper Peninsula for the distillation of wood. Michigan plants produce finished acetone, wood alcohol and gray acetate of lime. In connection with many of the plants are also charcoal blast-furnaces.

PAPER

Michigan is a very important paper State. The district around Kalamazoo and from there west to Lake Michigan is the most important book paper district in the country. At one place or another in the State nearly every kind of paper is made, but the principal output is book paper.

There is no mill in the State making soda pulp. Sul-

phite pulp is made by both the slow and the quick cook process. The reworking of old paper is a very important feature of most of the mills. There are boxboard and strawboard mills, one concern makes parchment papers of all sorts, and another makes a specialty of unusual finishes and colors for covers, photograph mounts, etc. There are 30 to 35 paper mills in the State.

One interesting feature of the paper industry is that it is the second industry in the State to unite in maintaining co-operative research. The Michigan Gas Association has for many years maintained a research laboratory and fellowship funds at the University of Michigan, and in 1915 a group of paper manufacturers united to found such an arrangement for the paper industry. The war has greatly interfered with the plans, as might be expected, so that not nearly as much has been accomplished as in the same length of time had conditions been normal.

DYES AND ORGANIC CHEMICALS

The State has two dye plants—the Holland Aniline Co. and the Dow Chemical Co. The Holland Aniline Co. confines itself to a few dyes, including methyl violet, sulphur browns and blues, and bismark brown. The Dow Chemical Co. has long been a producer of chloroform, the manufacture of which was indicated by its production of chlorine in connection with the bromine process. From this, at the beginning of the war, it was only a step to other simple organic chemicals, then the more complex ones, and finally dyes.

PAINTS AND VARNISHES

The State contains two of the largest paint and varnish plants, together with a number of smaller ones. The Acme White Lead & Color Works and Berry Bros., both of Detroit, are among the most important plants in the country in their respective lines. There are also the Boydeell Bros. White Lead & Color Co., the Detroit Graphite Co., the Detroit White Lead Works and the International Color & Chemical Co.

TANNING AND TANNING MATERIALS

There is a large number of tanneries all over the State. All kinds of leathers are made—sole leathers, belting, harness, as well as uppers and fine leathers. Chrome, oak, hemlock and tropical extracts are used.

The Michigan Tanning & Extract Co. operates a number of plants, mainly in the Upper Peninsula, for the manufacture of tanning extracts from hemlock bark. The bark is leached in open tanks, and the extract concentrated in multiple effect evaporators.

OTHER ORGANIC INDUSTRIES

The U. S. Rubber Co. has a plant in Detroit—the Morgan & Wright plant—making rubber tires of every description. The manufacture of pharmaceutical products is represented by Parke, Davis & Co., the Fred-

erick Stearns Co. and the Digestive Ferments Co., all of Detroit.

The Frank Chicory Co. has several plants through the State for the manufacture of chicory products. The famous plants at Battle Creek making all sorts of special and standard food products must be remembered. There are several plants for the making of condensed milk; and in the southwest part of the State is an important grape district in which are grape-juice plants. And in this connection it is possibly appropriate to mention the Detroit Reduction Co., which takes Detroit's garbage and converts it into fertilizer and grease by the ordinary process of digesting with steam under pressure.

CERAMIC PRODUCTS

Michigan has plenty of clays, but has little in the way of ceramic industries except the manufacture of common brick. There are a few tile plants, but as a general thing the clay-working industries are confined to ordinary building brick.

CEMENT AND BUILDING MATERIALS

The manufacture of portland cement in Michigan was begun in 1896. In 1901 the State made 1,000,000 bbl., and was the third largest producer in the country. In the last ten years its rank has been fifth to eighth, and it has made from 4 to 5 per cent of the total output of the whole country. Owing to the fact that the important limestone deposits are in the northern part of the State and relatively inaccessible, most of the plants use marl. One plant successfully used the residue of calcium carbonate obtained in making NaOH from Na_2CO_3 . This is the Wyandotte Portland Cement Co., operating on the waste from the Michigan Alkali Co. In all, there are 11 active plants making portland cement in Michigan. Table VI gives the Michigan cement production for the years 1913 to 1917 as compared with that of the total in the United States.

TABLE VI—MICHIGAN CEMENT INDUSTRY

Year	No. Mills	State's No. Rank	No. Kilns	Daily Capacity Bbl.	Total U. S. Production Bbl.	Michigan's Production, Bbl.	Michigan's per Cent of U. S. Total
1913	11	8	83	19,900	92,097,131	4,186,236	4.21
1914	11	7	77	19,100	88,230,170	4,285,345	4.85
1915	11	5	71	20,800	85,914,907	4,765,294	5.55
1916	11	7	68	20,650	91,521,198	4,919,023	5.37
1917	11	7	..		92,814,202	4,688,899	5.06

Gypsum is always present in salt beds, and is the principal source of trouble in salt making. As one superintendent put it, "When the Lord made salt beds He put some gypsum in so that the salt maker wouldn't have too easy a time." And the small amounts of gypsum that form on the tubes and pipes in salt plants probably represent more time and money than all the gypsum produced as a primary product. However, Michigan has deposits of gypsum that are worked for gypsum as such. Eight plants handle this material, making land plaster, plaster of paris and special forms such as blocks, tile, etc. In the last ten years Michi-

gan has been in third or fourth place in this country in quantity and value of gypsum products produced. Table VII gives the Michigan gypsum production for the years 1913 to 1917 as compared with that of the total in the United States.

The State has many deposits of limestone that are worked; varying all the way from extremely high calcium material to dolomites. The sugar industry of the State is almost entirely supplied with high calcium limestone from the northern part of the Lower Peninsula. The Solvay Process Co. gets its limestone from Sibley, a few miles below Detroit, while the Michigan Alkali Co. brings its limestone from Alpena.

In spite of its many deposits of brick clays, Michigan has been the first State in production of sand-lime brick since the process was introduced in this country. Michigan produced 26 per cent of the total for the United States in 1917. There are ten or twelve plants in the State, making building brick almost exclusively.

During the war, when every effort was being made to get optical glass with the maximum transmission, so that when made into periscopes and range finders the range of vision might be as great as possible, the principal problem seemed to be to keep minute traces of iron out of the glass. In their search for iron-free raw materials, the glass people finally came to Michigan for their sand. The American Silica Co., operating a deposit near Detroit, was able to furnish a purer sand than any other deposit in the country.

CONCLUSION

The enormous growth of the automobile industry has stimulated every form of metal working and fabricating industries; which means that there is a corresponding demand for the products of the various chemical and semi-chemical processes. For of the chemical and related industries it is especially true that they produce supplies for other industries; in few cases do they make articles which go directly to the ultimate consumer.

With the chemical industries resting on the sure basis furnished by the salt and alkali industries, and the markets assured by the enormous general manufacturing interests of the State, there seems to be a very bright future for Michigan as a great technical State.

An American Chamber of Commerce for Havana

A plan is apparently assured to form an American chamber of commerce at Havana similar to organizations of this kind at Paris, London and several other cities.

It is intended to have the work of the organization extend to all parts of the island and to make it a factor of much value in American trade. It is believed that the organization can be of service in matters of transportation, prompt passage of merchandise through the customs, credits, advertising, etc.

The American Minister has been active in bringing about the new organization, in the interests of which the first meeting was held at the American Legation and attended by more than 100 American citizens. At this meeting, held on July 15, 1919, a temporary organization was effected, and at an early date it is expected to complete the organization and secure suitable quarters and a permanent secretary and such other assistants as may be required. The consulate general is taking an active part in the new project and will be able to render much assistance to it.

TABLE VII—MICHIGAN GYPSUM INDUSTRY

Year	Ground to Land Plaster, Tons	Cal-cined, Tons	Sold as Crude, Tons	Total Production, Tons	Total U. S. Production, Tons	Mich. per Cent of U. S. Total

Natural and Industrial Resources of Wisconsin

A Description of Some of the Mineral Resources and a Review of Some of the Chemical Industries—
Present Status of the State's Zinc Industry and Prospects for
Future Development

Raw Material Resources of Wisconsin

BY W. O. HOTCHKISS
State Geologist

WISCONSIN is very close to an average State in almost all particulars. The average State should have a standing of about 2 per cent, and since there are 48 States Wisconsin has more than her 2 per cent of wealth and population and almost exactly 2 per cent of the area of the United States. In raw mineral reserve products, however, Wisconsin has only about half of the average of the country, its total mineral production being about 1 per cent of that of the United States. Of the important mineral resources, Wisconsin produces no coal, no copper and no precious metals, so barring these from the list of products of the country Wisconsin has considerably more than the average State in production of raw mineral materials.

ZINC ORES

The principal mineral resources of Wisconsin are zinc, iron and stone. Before the World War zinc ore and iron ore were approximately equal in value, but owing to the great demand for zinc during the war the production of that metal increased nearly four times in value, so that in 1918 the zinc ore produced in this State was worth over \$5,000,000. In 1916 and 1917 the value each year was between \$7,000,000 and \$8,000,000. The metal content of the ore was worth approximately double the value of the raw material. On account of this great development in the zinc industry it is now the largest single item in value of the mineral production of the State. Zinc mines are located

WINDSOR MINE

in the southwestern portion of the State and the district overlaps a little into the adjacent States of Iowa and Illinois.

On the average, the zinc mines are less than 200 ft. in depth, and as the ore comes from the mine it contains considerable limestone, and iron sulphide in the form of marcasite. The limestone is eliminated by

concentration, and the marcasite and zinc sulphide are then sent to a roaster in which the marcasite is given a magnetizing roast and separated from the zinc sulphide in a magnetic separator. During the war plans were made for installing contact acid plants to use the gas from some of the largest roasters. Some of the mines have their own roasters, but many of them ship their ore to central plants, where the marcasite is removed from the zinc sulphide.

The principal production of zinc is from the mines of strong companies. The Mineral Point Zinc Co., a subsidiary of the New Jersey Zinc Co.; the Wisconsin Zinc Co., a subsidiary of the American Zinc Roasting

GRANITE QUARRY AT BERLIN

& Smelting Co.; the Vinegar Hill Zinc Co.; the Frontier Mining Co.; and the Field Mining & Milling Co. produce approximately three-quarters of the total zinc production. Each of these companies operates several mines.

The crude ore before milling varies greatly in zinc content. Some mines will produce as little as 5 per cent of concentrates from the ore and others will produce more than 20 per cent of concentrates. In some cases, while running on especially rich ore bodies, a much higher percentage of concentrates is recovered. The ore going to the mill is much richer than the Joplin ore.

In the northern portion of the district, in the vicinity of Highland and Mineral Point, some portions of the ore bodies have been altered to zinc carbonate. This finds a ready market at the zinc oxide works of the Mineral Point Zinc Co. at Mineral Point, Wis., which is one of the largest zinc oxide plants in the United States and draws its ore supplies not only from this district but from the far West and Southwest, and even from Mexico.

IRON ORES

The iron ore of Wisconsin is produced at present from four districts. The largest tonnage comes from the Gogebic Range, which lies in the extreme northern part of the State and extends over into Michigan, where

MONTREAL HEAD FRAME

the main production of the Range is secured. In the northeastern corner of the State, in Florence county, there is a small production, and in the Baraboo Range, in the south central part of the State, there is one operating mine. All of these ores are Huronian and of the usual Lake Superior type. In Dodge county, about 50 miles northwest of Milwaukee, there are Ordovician ores similar to those in Birmingham. These are of a much lower grade than the Lake Superior type of ore. Large reserves of low-grade ore have been thoroughly proved in this district, and also in the Baraboo district. There are in addition to these producing districts a number of districts in the State which offer great promise for the production of iron ore when

BRILLION LIMESTONE QUARRY

concentration of low-grade material is undertaken. In the western end of the Gogebic Range and in the Black River Falls district there are literally hundreds of millions of tons of magnetic formation that will doubtless be concentrated before many years.

POSSIBLE UNDISCOVERED IRON RANGES

In the northern half of the State there are great areas in which the glacial drift entirely obscures the rocks but in which there are doubtless to be discovered important iron ranges. The State Geological Survey has been carrying on for the last eight years a comprehensive program of geological and magnetic study of this portion of the State for the purpose of discovering all areas in which exploration appears to be warranted. Exploration which has followed upon published reports has proved the existence of Huronian rocks such as are associated with the Lake Superior iron ores, so that definite proof has been secured that there are first-rate opportunities for the discovery of new iron ranges. Only a small fraction

of the total area to be examined has as yet been covered.

While Wisconsin is not in a class with Minnesota as an iron ore producer, it ranks fifth among all the States, and its annual production, if loaded upon the largest size of ore cars, would make a continuous train from the State line north of Chicago to Milwaukee, and from Milwaukee clear across the State to La Crosse. With its large reserve of low-grade ore, and the opportunities for the discovery of other Lake Superior iron ranges in the little known northern portion of the State, Wisconsin promises to stand high as an iron ore producer for many years.

Widely distributed over the glaciated northern portion of the State are marshes which contain bog ore. This ore is usually in comparatively shallow deposits

ROCK PILE NEAR NO. 4 SHAFT, MONTREAL MINE

of a few inches to a few feet in depth, but its character is such that it may in the future have a large value for special purposes.

STONE PRODUCTION

The third in rank of Wisconsin's mineral resources is its stone production. If under stone one included similar products and the derived products, such as lime, sand and gravel, Wisconsin's stone production would be worth more than its iron ore. In these days of concrete construction

and extreme activity in highway building Wisconsin is fortunate in having widely distributed over four-fifths of the State excellent glacial sand and gravels; and over the unglaciated portion, and in a considerable part of the glaciated portion as well, abundant local supplies of limestone, trap rock and granite, which make the best of materials for highway and structural purposes. In 1917 Wisconsin produced over \$1,000,000

STURGEON BAY STONE QUARRY

worth of lime. Nearly \$870,000 worth of this was used for building purposes, about \$90,000 worth was used in the manufacture of paper, and large amounts were supplied to blast-furnaces for flux, to chemical works, to tanneries, and to glass factories, and there is a small but rapidly growing use of this material as a fertilizer for sour soils. Limestone was produced in the State to a total value of nearly \$1,200,000 in 1917. Nearly three-quarters of this value was represented by crushed stone used for road making and for concrete construction. The largest other item was flux for blast-furnaces, with almost equal values for the production of rubble and riprap stone. Rough and dressed building stone was produced in minor amounts, and small amounts of limestone were used for paper mills and agricultural purposes.

LIMESTONE QUARRY NEAR
WAUKESHA

THE STATE'S GRANITE RESOURCES

Wisconsin possesses important resources in granite, some of the finest monumental stone in the world and the hardest and most durable granites being quarried in the State. The total production in 1917 was valued at \$1,250,000. Of this total minor values were represented in rough stone, rubble, riprap and crushed stone amounting to somewhat over \$150,000. The remainder, about \$1,100,000, was almost evenly divided in value between dressed and monumental stone and paving blocks. Wisconsin paving blocks are used in all the principal cities in the northern Mississippi Valley, as far south as St. Louis and as far east as Cleveland.

In 1917 Wisconsin produced nearly \$300,000 worth of sandstone and ganister. Over half of this value was quartzite used for the manufacture of refractory brick and produced in the vicinity of Baraboo. This quartzite is very pure silica, seldom containing as much as 1 per cent of impurities, and its pure and refractory character make it especially valuable for bricks for furnace linings. Some of Wisconsin's sandstones make excellent building stone of a beautiful, soft light buff color. When the war cut off the supply of foreign material, stone from Wisconsin's sandstone quarries was selected to be used for finishing a cathedral in New York City.

Wisconsin gravel is widely distributed over the State and is used in vast quantities for road construction. Nearly \$500,000 worth was used for this purpose in 1917, which represented nearly 1,500,000 tons. Nearly 500,000 tons, valued at \$67,000, were used for railroad ballast. Considerable quantities of sand were used for molding sand and paving sand, and nearly 300,000 tons were used for building sand. The total

value of sand and gravel production in 1917 was nearly \$1,100,000.

If the production of limestone, lime, granite, sandstone, and sand and gravel be included under the general head of stone industry, Wisconsin's production in 1917 was valued at approximately \$4,800,000. These figures are for value at the quarry or pit and do not include any transportation charge. If transportation to the consumer were included as a part of this industry, the stone industry in Wisconsin could be said to bring in nearly \$15,000,000 a year to its citizens.

OTHER RAW MATERIALS

Mineral waters of Wisconsin are world famous. In former days when the discreet citizen decided that he had enough of stronger fluids he was very likely to

MAYVILLE SHAFT, NORTHWESTERN IRON CO.

ask the bartender to fill his glass with a world-famous brand of Wisconsin mineral water. Wisconsin mineral waters are shipped all over the world, and in both quantity and value Wisconsin leads all other States in the Union. In 1917 the total production at the spring was valued at \$1,362,000, an average price per gallon of 22c. This was less than the usual production because of the stoppage of world trade by the war. The main production of Wisconsin's mineral waters comes from

NO. 4 HEAD FRAME, MONTREAL
MINE

the city of Waukesha. The clay products of Wisconsin include chiefly brick and tile, and the value of the production in 1917 was \$1,114,000. The glacial clays of Wisconsin are very abundant, and there are small local brick plants, with a few large plants, which supply considerable areas. These clays are not suitable for fire brick or paving brick, but a good quality of front brick is made in some of the yards.

CARY MINE AND STOCK PILES

Next in order of Wisconsin's mineral production comes the lead which is recovered as a by-product from the milling of zinc ores. In 1917 the value of the metal content of Wisconsin lead was a little over \$700,000. Another product from the zinc mines, which is of much less importance in money value, is the iron sulphide, which is sold to the manufacturers of sulphuric acid.

Chemical Industries of Wisconsin

By O. L. KOWALKE

A WIDE variety of chemical industries is represented in Wisconsin, but among these the leather and paper industries are the most important on the bases of value of product and number of men employed.

The leather industry of Wisconsin ranks fourth among all the industries of the State and third in the leather industry of the United States. The employees constitute 10.5 per cent and the value of the products, \$42,200,000, constitutes 11.5 per cent of the total for the country in 1914. Milwaukee is the second city in the country on the bases of size of tanneries and the value of the products. The principal product is "calfskin upper," 2,292,800 sides, of which more is made here than in any other State; sole leather, with 1,122,200 sides, comes next in order, and is followed by harness leather, with 631,787 sides. Of the latter more is made in Wisconsin than in any State in the Union.

Wisconsin is one of the leading pulp and paper producing States in the country, being surpassed in the consumption of wood for this purpose only by Maine and New York in the order named. There are 30 ground wood, 20 sulphite and 5 sulphate pulp mills in the State, which in 1917 produced about 400,000 tons of pulp, consisting of 45 per cent unbleached sulphite, 38 per cent mechanical, 8 per cent sulphate and 9 per cent bleached sulphite. Besides the wood pulp paper, such as news, writing, book, tissue, wrapping, etc., considerable amounts of rag paper and container board are made, amounting in all to 480,851 tons in 1917. A number of specialties were developed in Wisconsin for war purposes, such as cellulose, a wood pulp substitute for absorbent cotton; special waterproof containers for packing and shipping shells and other war supplies, and the use of waste hemlock bark, produced from the roasting of wood, for the manufacture of hemlock extract. Other specialties, not for war purposes, are fiber rugs, filter mass (the plant being the largest in the United States), and molded pulp products.

There are several chemical industries that rank well

There are deposits of carbonaceous schists in Wisconsin, in which the carbon has been very much altered so that it is clearly graphitic. One of these deposits has been used for the manufacture of a very good grade of graphite paint.

LARGE AREAS OF PEAT BOG

An undeveloped mineral resource of Wisconsin which bids fair to be of great importance in the future for a wide variety of purposes is found in its great areas of peat bog. The State Geological Survey examined peat bogs of a total area of 121,000 acres, in which it was estimated that there is available at least 150,000,000 tons of air dried peat. It was further estimated that there are over ten times as many deposits as were examined, and a general estimate is given that there are between 2 and 3 billion tons of dried peat available in Wisconsin. Much of this will doubtless be drained and used for agricultural purposes, for which it makes very valuable soil, but as the chemical industry in this country increases chemists are bound to find more valuable uses for large quantities of this material.

to the front in the country. Of these the rubber industry ranks sixth in the value of products, \$7,382,108, for five establishments in 1914, the principal product being automobile tires. The 11 soap factories, with an output valued at \$2,894,000, rank tenth in the country in this industry on the bases of persons employed and value of the products. The increase in value of the finished products over the raw materials is 117 per cent. In this respect Wisconsin is led by only one State, which gives a measure of the high grade of soap made. Gas for domestic and municipal consumption made in 47 plants is valued at \$5,294,000, which puts the group in tenth place in the industry. Not included in the group of 47 gas plants are two by-product coke-oven plants, in one of which 250 ovens are in operation, producing 1800 tons of coke daily.

The census of 1914 ranks Wisconsin nineteenth in a group called chemical industries, comprising 395 establishments engaged in the manufacture of acids, sodas, alums, coal-tar products, cyanides, bleaching materials, chemicals by electrolysis, plastics, compressed and liquefied gases, and other chemicals. Most of these materials are made here. Sulphuric acid is made in two plants, one using the contact process; nitric acid is made in one plant; three plants are engaged in making bicarbonate and sal soda. The compressed and liquefied gas industry has kept pace with the growth of the foundry and machine tool industry; two plants make compressed acetylene; two make compressed oxygen and hydrogen, while at one plant of considerable size compressed oxygen is obtained from the air.

MISCELLANEOUS OTHER INDUSTRIES

Another group of industries not included in the above list but of equal importance is worthy of consideration. Of major importance in this group are four beet sugar factories having a combined daily capacity of 2800 tons of beets; one glue factory capable of handling all the wastes from the Wisconsin tanneries in addition to large amounts of raw materials shipped in from other sources; and a match factory of large capacity. The dry battery industry ranks third in its group and its

output is about 2 per cent of the total in the country. In the manufacture of dynamite and permissible explosives, Wisconsin ranks sixth among the seven States producing nine-tenths of these commodities. Other industries on which statistics are not available include the following:

Industry	Number of Establishments	Industry	Number of Establishments
Lime	30	Wood alcohol and acetate of lime	3
Fertilizers	8	Glycerine	2
Paints ready to use	6	Insulars	2
Iron buff and other colors	3	Baking powder	2
Zinc oxide	1	Electroplating	10
Varnish	1	Glass bottles	1

A number of industries were established as a result of the war. Among these is the production of potash from wood ashes. In 1917 21 plants were in operation in Wisconsin and 25 in Michigan, which together produced 1035 short tons of crude potash, or 2 per cent of the total potassium oxide production in the United States. The initial cost of the average sized potash plant, including the building, was between \$3000 and \$4000.

The production of high explosives in Wisconsin in 1916 amounted to 6,515,032 lb., which was 2½ per cent of the total manufactured in this country. Closely associated with the production of high explosives is the manufacture of coal-tar dyes and dye intermediates in one large plant. This plant made a number of intermediates in large quantity and is now well established for peace-time production.

University of Wisconsin.

Zinc in Wisconsin

By A. M. PLUMB

PROBABLY the history of few mining districts could be as definitely divided into two epochs as that of the Wisconsin zinc mining district. From the advent of the whites into the section in the last quarter of the seventeenth century up to the end of the nineteenth century, the district was practically a lead district. The history of the pioneer lead miners and smelters up to the beginning of the twentieth century has been fully covered by numerous writers, and in most cases these histories are closed with the nineteenth century, which marks practically the beginning of the zinc industry, and simultaneously the ending, to all intents and purposes, of the lead industry.

There is, of course, an important lap of these epochs in the case of the Mineral Point Zinc Co. At Mineral Point numerous efforts have been made to produce zinc metal and zinc oxide, which have all been described, from which has evolved the present Mineral Point Zinc Co., which has discontinued any attempts to produce metal, but has been successfully producing oxide by the old Wetherill process for many years, ores being derived from numerous distant points, even as far south as New Mexico, and as far west as Nevada.

PRODUCTION OF ZINC FROM MIXED SULPHIDE ORES

At the beginning of the present century, the possibility of producing zinc from the mixed sulphide ores attracted the attention of miners and metallurgists from many different mining sections of the country. The presence of pyrite and marcasite was so general as to make the direct production of smelting concentrates out of the question, except in rare, isolated cases. In

the early '90s an effort was made to effect a separation of the zinc blende and marcasite by a secondary treatment. Prof. R. P. Blake, who had some advance information on the physical properties of the Wisconsin marcasite, attempted to separate these products by a preliminary roast followed by a wet jigging operation. On account of the fact that the marcasite particles when roasted are affected in a manner very similar to the effect upon popcorn when subjected to heat, hydraulic diameters of these are materially changed. Particles after roasting will be found to have numerous fissures extending toward the center of the particle, and, in addition to the fissures, the whole mass is left in the form of a sponge. While it is probably a fact that this particle will have slightly less specific gravity than the blende particle, its shape and structure is such that it will be found to ride considerably higher on a jig bed than will the zinc.

This attempt resulted in some surprisingly high grade finished product, but the loss of zinc in tailings was so great as to render the process of practically no economic value. This excessive loss was almost entirely a loss of fines. While the resultant product of a jigging separation in Wisconsin is considered coarse, i. e., all through a 2-in. screen, the roasting operation produces a considerable amount of extreme fines on account of decrepitation, and most of this in the process above described will be lost.

ORES SEPARATED MAGNETICALLY

Early in 1900 some experiments were made which resulted in the present successful separation of these ores, which is accomplished by a preliminary roasting and subsequent magnetic separation. The first commercial attempt along this line can easily be considered a complete success. The operation consisted in passing the ore through a revolving type of furnace similar to a Howell-White, but having a dam at both the feed and discharge ends to retain a quantity of ore in the cylinder so that the passage through the apparatus was retarded. The roasted product is then passed to almost any of the types of magnetic separator, resulting in a surprisingly complete separation.

This process was considered a part of the standard equipment in the Wisconsin field until the year 1915, when the Wedge type multiple hearth roaster was introduced, with great success, after the minor initial difficulties had been surmounted. The savings, however, over the older process have been practically negligible aside from the dust loss. In the old type of furnace the dust loss was substantially 5 per cent, whereas in the new type it is about 1 per cent. The separations effected are practically identical.

I have mentioned that the simultaneous occurrence of marcasite and zinc blende was the great problem in the beginning of this industry. It is then somewhat surprising to discover the extreme kindness of nature when the process is finally evolved, in that a very large percentage of the objectionable gangue materials is found to be associated with the marcasite. As an example, out of an ore running 39.6 per cent Zn, 15 per cent Fe and 2.9 per cent CaO, the magnetic material discarded as tailings runs 4.8 per cent Zn, 48.5 per cent Fe, 4.9 per cent CaO and 3.35 per cent ZnS. The finished product, containing 95 per cent of the zinc contents of the feed, runs 61.5 per cent Zn, 1.6 per cent Fe and 2 per cent CaO.

This result is accomplished by following somewhat different lines than would ordinarily be attempted. It is the first thought of most metallurgists when difficulties in separation arise to crush to a smaller size. In Wisconsin this turns out to be a mistake, since any additional crushing will liberate some of the lime and insoluble which are components of the marcasite particles, so that finally the separation in Wisconsin is accomplished with best results at as coarse size as the mill product can be produced.

On the other hand, there are some natural properties which if not guarded against will lead to economic loss. The marcasite particle after roasting is made up of a combination of a so-called artificial pyrrhotite and amorphous iron oxide. This latter forms the outside surface and is so soft as to be easily crushed between the thumb and finger. It is then necessary to subject this product to the least amount of handling, since the dust resulting from abrasion is not magnetic and will be found as an iron content in the finished concentrate.

BLAKE-MOERSCHER ELECTROSTATIC PROCESS

At about the same time that the magnetic separation was instituted in Wisconsin, a small plant was built for purposes of testing out the Blake-Moersch electrostatic process. This was an ingenious device, utilizing the differences of conductivity between the zinc blende and the marcasite. This first plant demonstrated that there was a strong possibility of this operation being successful, especially since the iron product had a marketable value as a source of sulphur, and made a salable zinc product.

In 1908 this process made its appearance in a slightly different form in the Huff electrostatic separator. A plant on a moderate scale, utilizing this process, was built and operated with more or less success for 3 years, when the plant was destroyed by fire and was not rebuilt. Probably the one determining factor in the abandonment of this process was the necessity of crushing the mill concentrates in order to effect a separation, which resulted in the liberation of lime and insoluble as described above.

OLD AND PRIMITIVE METHODS PROVE BEST

The district as a whole has furnished its quota of incidents which have added to the general fund of mining and metallurgical experience. It has for the thousandth time been demonstrated here that metallurgists coming in from other districts should avail themselves of the experience of the natives, giving the prevailing methods careful thought before radical changes are decided upon. Nearly all of the mining and milling operations here are of almost primitive type, but when the outsider has attempted to improve materially upon these by any radical change, he has come to grief.

One feature of the average mining proposition here is that it is short lived, which of necessity means the cheapest installation that will make a respectable metal recovery and pay its entire cost, together with a profit, in from 3 to 5 years.

Another lies in the fact that concentrates must be re-treated before marketing. I have said above that nature has been most kind in providing physical properties which ultimately benefit the operation. A further instance of this lies in the fact that in a coarse jigging operation the percentage of recovery of zinc is much higher than that of iron. The average oper-

ation results in a metallic zinc saving of from 60 to 70 per cent. This large loss appeals to the outsider at once as an opportunity for radical improvement. He will find, however, in most cases that his efforts, which might be called metallurgically successful, will fail economically due to the fact that the product he recovers will not be worth its cost.

Flotation has not yet made its appearance except in the most superficial experimental way. This process does hold out some promise, especially on some of the larger propositions which have from 10 to 20 years' life, and I shall be surprised if within a very few years there are not some successful flotation plants operating in this field, especially since the selective processes producing zinc direct from other sulphides show strong promise.

PROSPECTS FOR FUTURE DEVELOPMENT

Among the attractive features of the district—it is a most livable country, is traversed with better than average roads, and life here will be found to hold many compensations over that in the average mining camps. At first blush I should say that more in the way of prospecting and equipment can be accomplished per dollar here than in any other mining section I have seen.

It goes without saying that there have been the usual amount of wildcatting propositions. There have been also the usual well meant but misguided expenditures of capital. Altogether, the district will show a fair return on ventures well managed, and there are no reasons apparent why the present activity should not continue for another century.

Minnesota State-Owned Iron Mines

HYDRO-ELECTRIC SYSTEMS, NORTH CENTRAL STATES

Power Systems of the North Central States

Hydro-Electric Systems and Large Steam Plants in Four States Offer Future for Electrochemical and Chemical Industries—Extension of Transmission Lines Opens Way for Development of Natural Resources

BY CHESTER H. JONES

HYDROELECTRIC power in the district of four States of which Chicago is near the center has already become a factor in the development of the chemical industries, and an examination of the potential power resources of those States, individually, reveals the fact that vast coal areas supplying energy through large steam generating units supplement the water power stations to meet the demands of the territory. The district divides itself into the hydro-electric States of Wisconsin and Michigan, and the coal-bearing States of Illinois and Indiana. Keokuk Dam is the exception in the steam power areas. An examination of the map on page 343 will show the relation of local resources in water power to the total power in the United States.

Water-produced electric energy is not of necessity required for electrochemical manufacture. It is not to be forgotten in the consideration of the two sources of energy that a close competitor exists in the steam plant located near the coal supply. A good number of electrical engineers agree that hydro-electric energy transmitted over long distances, and supported by emergency steam plants, is subject to high cost, because of

interest on investment, maintenance of line and steam plant and depreciation on system. For the future power of the chemical industry in Illinois and Indiana we must look to the coal fields.

Wisconsin

The State of Wisconsin is peculiarly adapted for water-power development. The slope of the land lies in one direction, commencing at a ridge about 30 miles from and parallel to the shore line of Lake Superior, sloping to the southwest, the entire drainage flowing into the Mississippi River. The many lakes act as reservoirs for each local drainage area, making it possible to hold the storm waters and thus to secure an ideal condition for continuous operation of water-power plants.

The total capacity of generating plants, both steam and water-power, within the State is 350,000 kw., with a possible hydro-electric generating capacity of 613,342 kw. There are now installed 129 hydro-electric plants, the majority of which are of small capacity. The field for future development of water power will be seen from these figures to be enormous.

FISK AND QUARRY ST. GENERATING STATIONS, COMMONWEALTH EDISON CO.

HYDRO-ELECTRIC POWER RESOURCES IN THE U. S.

CROTON DAM, MUSKEGON RIVER

The extension of transmission lines in the southwestern part of the State is forming an interconnected system, and should eventually serve the consumers as a single unit.

WISCONSIN-MINNESOTA LIGHT & POWER CO.

The Wisconsin-Minnesota Light & Power Co. operates a series of interconnected hydro-electric plants in the western part of Wisconsin, furnishing power, in addition to this district, to Minneapolis and other Minnesota points. The principal generating stations are at Wissota, Eau Claire and Cedar Falls. The largest of these is at the Wissota Dam, located on the Chippewa River at the outlet of Wissota Lake.

The Chippewa River is the greatest of all the power streams in the State, carrying at the Falls a drainage of 5600 sq.m., and the Red River, its tributary, brings an additional drainage from an area of 1997 square miles.

The generating station equipment at Wissota power house consists of six 6600-kw. water-driven vertical generators, together with necessary auxiliary apparatus. Transmission line operates at 110,000 volts, and about 30,000 kw. is consumed by the Northern States Power Co., operating in St. Paul and Minneapolis, Minn.

The stations at Eau Claire and Cedar Falls each contain four 6500-kw. water-wheel generators. Other hydro-electric plants are located at Red Wing, Minn.; Cedar Falls, Chippewa Falls, Menomonie, Neilsville, Rice Lake, Stanley, Viroqua, Sparta, Tomah and La Crosse, Wis. The transmission voltages are 13,200, 33,000, 66,000 and 110,000 volts, and power is supplied to railroad shops, pulp mills, sugar factories, tire factories, iron and steel works, and miscellaneous industries.

Interconnected with this system is that of the Wisconsin Railway, Light & Power Co., with its water-power plant on the Black River, near Hatfield, below the outlet of Lake Arbutus. The water is taken into the power canal at Hatfield, transmitted 2.6 miles with a

fall of 94 ft. to the power house, where it enters through two tubes 10 ft. in diameter to drive two 3200-hp. water wheels. Power is transmitted over No. 2 copper wire to Winona, where it connects with the Wisconsin-Minnesota Power Co. system and with the La Crosse Co.

WISCONSIN EDISON CO.

The property of the Wisconsin Edison Co. consists mainly of steam-power plants interconnected by transmission lines covering the district from Milwaukee west to Lake Mills, south to Delevan and through Burlington back to Milwaukee. A line also extends from Milwaukee through to Kenosha. Power is transmitted at 4000, 13,200, 26,400 and 66,000 volts.

This system receives power from hydro-electric plants of the Southern Wisconsin Power Co. at Kilbourne, utilizing the total output of 6000 kw., and also from the hydro-electric plant of the Wisconsin River Power Co. at Prairie du Sac. This latter station generates a total capacity of 16,500 kw. at 2200 volts, 25 cycle, from a total of six machines.

An examination of the map will show that majority of the water-power plants in Wisconsin are not con-

OUTDOOR SUBSTATION, MUSKEGON HEIGHTS

nected with any considerable lengths of transmission lines, outside of the above mentioned plants. One of the larger plants of the State is at St. Croix Falls, located on the St. Croix River and furnishing power for stations in Minnesota. This station contains six units generating 15,000 kw. and delivering energy to the transmission line at 6600 and 66,000 volts. There is also a station at Somerset on the same river which has a capacity of 3000 kw., with four units all delivering power principally to the St. Paul Co.

Michigan

The State has a total potential water-power resource of 294,500 hp. and a present steam and water power available in generating stations of 480,000 kw. One hundred and sixteen hydro-electric plants in whole or in part are in operation. The majority of these are isolated plants or systems with short transmission lines. The largest system in the territory in number of plants and length of transmission lines is the Consumers Power Co., a Hodenpyl-Hardy property.

CONSUMERS POWER COMPANY

This system, starting with a chain of six water-power generating stations on the Au Sable River, transmits energy south through the Saginaw district, through Lansing to Jackson and Battle Creek, connecting in with six hydro-electric plants on the Kalamazoo River, thence northward to plants on the Grand, Muskegon and Manistee rivers, forming a horseshoe system over the territory of the Lower Peninsula.

One of the large chemical works using this energy is that of the Dow Chemical Co. at Midland, where bromine, bromides, chlorine and miscellaneous chemicals are produced. Other plants along the line are the Michigan Alkali Co. at Wyandotte, manufacturing soda ash, and the North American Co. at Bay City, manufacturing soda ash and chlorine.

The Pennsylvania Salt Co. at Detroit, making chlorine and alkalis, is on the line of the Detroit Edison Co.

Among other developments on the Au Sable River is the Cooke power house. On the southern loop of the system additional energy is generated at Grand Rapids, Jackson, Saginaw, Bay City, Battle Creek, Kalamazoo, Pontiac, Manistee and Cadillac. The hydro-electric plants have an installed capacity of 101,000 hp., and the steam plants 103,000 hp., i.e., the total is equal to nearly half of the total installed power in the State. There are 1400 miles of transmission lines, steel tower construction, located almost entirely on private rights-of-way.

In addition to power furnished for the chemical in-

INTERIOR COOKE POWER HOUSE

dustries above outlined other prominent industries are factories for automobiles, agricultural machinery, food products, paper and pulp mills, brass and metal products, stoves, wagons, and also electric railways. The field for development of ceramics is said to be large along this property; this is also true of several large undeveloped chemical deposits.

Among the larger water-power plants in the north are Junction Dam on the Manistee River and Croton Dam on the Muskegon River. The pictures shown herewith give a good idea of the Croton Dam and a substation in this section. Reference to the map will show the proximity of the transmission lines of the Detroit Edison system to this property and doubtless it will not be long until interconnection is made to form a system that will serve the whole Lower Peninsula.

THE DETROIT EDISON CO.

This company is controlled by the North American Co. and operates the largest system of steam generating plants in the State. Energy is also supplied from four hydro-electric plants on the Huron River, near Ann Arbor. The two plants at Detroit generate from steam a total of 198,000 kw. The total water-power capacity near Ann Arbor is 6075 kw.

UPPER PENINSULA PLANTS

The Escanaba Power Co. operates hydro-electric plants on the Escanaba River at Groos, Wells and Chandler Falls with a total of 3750 kw. capacity transmitted at 6600 volts.

There is a 3000-hp. water-power plant under construction at Superior Falls, Wisconsin, for the purpose of supplying energy to Ironwood and Bessemer, Michigan.

A 3700-kw. plant on the Menominee River supplies energy to Menominee over a 3300-volt transmission line. There are also similar plants at Newaygo, for the Portland Cement Co., at Sault Ste. Marie, and at Marquette all in northern Michigan.

Illinois

The total electric power generated in the State of Illinois is 400,000 kw., which is produced chiefly from coal, with the exception of 17 hydro-electric plants. The principal water-power property is that of the Mississippi River Power Co. at Keokuk, Ia., while other plants worthy of note are the Public Service Co.'s generating station at Joliet, and the Sanitary District plant at Lockport. The total potential waterpower of Illinois is 345,660 hp., which exists chiefly in the Mississippi and Ohio rivers. The development of this power would be expensive, the flat topography necessitating the condemnation of large farming areas or the construction of heavy dikes. Reference to the article on raw material resources elsewhere in this issue will show the nature of the coal supply, and this coal is proving a better source of power than water for the territory.

MISSISSIPPI RIVER POWER CO.

Standing out pre-eminent beyond all other developments in this district and remarkable among the world's hydro-electric plants, the 231,500-kw. generating station of the Mississippi River Power Co. at Keokuk, Iowa, is too well known to be described in detail in this article. The plant is located in a section where

many raw materials are available for electrochemical reduction. The station contains thirty turbo-generator units with an overload capacity of 13,500 hp. per unit and transmissions are built as shown with the possibility of continual extension. Current is generated at 11,000 volts and transmitted at 110,000 volts. Of the total power generated 60,000 hp. is sold in St. Louis and a smaller amount to the smaller cities on the line. With 200,000 hp. now offered for sale there is still left a sufficient amount for large developments that may be desired.

In the construction of the dam and installation of the electric equipment, every imaginable contingency was considered, thus securing a reliable operation for many years to come. The dam proper, built out from the Illinois bluff, is of the gravity type and withstands all pressure upon it by virtue of bulk without bracing or reinforcement. The turbines and generators are specially designed by the best engineers available and are absolutely dependable as to operation.

The Mississippi River Power Co., with its plant on the Iowa side of the river at Keokuk, transmits energy into Illinois, after which the line follows the river to Halls, Ill., where tap is taken off for a cement plant at Ilasco, Mo. Energy is then transmitted further down the river on the Illinois side, crossing just above St. Louis with the line supplying the city. Energy is

also furnished to Alton, East St. Louis and Bellville, Illinois.

The Alton substation is one of the distribution points for the high tension service as well as that from the local steam plant. Incoming 66,000-v. lines and the outgoing 13,200-v. lines terminate here. The outgoing 66,000-v. power is carried over steel towers to a substation in East St. Louis. This line is brought through the Alton substation so that all the 66,000-v. energy received from Keokuk may be measured. There are two 13,200-v. 25-cycle lines connecting Alton and East St. Louis substations, while two additional 13,200-v. lines supply local points. The operating statistics of the Alton substation should show a good comparison between production costs of steam power, generated locally, and hydro-electric power transmitted over long distances.

The Central Illinois Public Service Co. operates a 2500-kw. frequency changer set in the Mississippi River Power Co.'s power house at Keokuk, Ia., and through this unit energy is supplied to the system which stretches across the central portion of Illinois. The 25-cycle energy from the water-wheel generators is converted to 60-cycle 11,000-v. energy which is conducted through conduits in the dam to the Hamilton substation on the Illinois side, where it is stepped up to 33,000 v. for the transmission lines. The line from Hamilton to Colchester is the second link for Keokuk power to the Central Illinois Public Service Co. This development releases 2000 tons of coal per month for use at other steam plants. It is stated that the operating expense is not reduced by the new supply, but additional capacity is secured and reliability of operation effected.

OTHER WATER POWERS

The Public Service Co. generates a total of 5778 kw. by water power, with its principal plant located at Joliet. This plant generates a total of 3600 kw. and is connected to a part of the company's transmission system. The property as a whole depends upon steam plants, however. The Sanitary District of Chicago receives power from its 35,000-hp. hydro-electric plant at Lockport. This power is consumed principally for street lighting within the District and has recently been increased by the completion of an auxiliary steam plant, 4000-kw. capacity, located at the terminal station, West 31st Street and Western Avenue, Chicago.

STEAM PLANTS

The Commonwealth Edison Co. of Chicago, by virtue of territory served, is the largest steam generating system in the State. The accompanying outline map shows location of generating and distributing points.

The following table shows the statistics in percentages of the connected loads of the plants of other companies within the Chicago territory as compared with the Commonwealth Edison Co.:

Company	Lamps		Motor	
	Incandescent, Per Cent	Arc, Per Cent	Horsepower Per Cent	
Commonwealth Edison Co.	95	96	89	
Other companies.	5	4	11	

The generating equipment is located in three principal power plants. The downtown and southern end of the city is served from the Fisk and Quarry street stations with a combined rating of over 200,000 kw., while the northern section is served from the Northwest station. The distribution of load between sta-

GENERATING AND DISTRIBUTING POINTS,
COMMONWEALTH EDISON CO.

tions is handled from the load dispatcher's office. Every facility for securing information in the shortest possible time is placed in the hands of this dispatcher. Maps, private telephone system, etc., are available for any emergency situation.

One of the features influencing the sale of power to chemical and electrochemical industries is the lower selling rate quoted for use of current during periods of the off-peak loads. In order to make the demand on the generating plants as uniform as possible the company may offer the use of power at certain times of the day at such a price per kilowatt-hour as to permit its economical employment in some of the chemical or metallurgical processes. This should apply to chlorine, and oxygen manufacture, where the operation may be intermittent.

INTERCONNECTING TRANSMISSION LINES

Supplementary to the general hydro-electric map appearing on page 341 the outline sketch herewith shows transmission lines owned by 28 companies in this locality. A considerable number of these companies are already interconnected for service interchange. There are also several connections between systems in Illinois and those in neighboring States. The Central Illinois Utilities Co. has a connection with the system of the Interstate Public Utilities Co. of Indiana. This connection, it is understood, is used only for emer-

GENERATOR ROOM, KEOKUK, IOWA

gency purposes on account of the difference in load characteristics of the two systems.

The East St. Louis Light & Power Co. has connection with the Union Electric Light & Power Co. of St. Louis by means of submarine cable under the Mississippi River. The contract covering this service was recently authorized by the Illinois Public Utilities Commission. The cable is now in use and is mainly for the purpose of supplying emergency and peak service to East St. Louis.

The larger companies operating in Illinois besides those mentioned are the Illinois Traction System, covering a large district in central Illinois; the Middle West Utilities Co., composed of a number of smaller plants, in the sparsely settled districts throughout the State; the Public Service Co. of northern Illinois, and the Southern Illinois Light & Power Co.

Indiana

The flat topography of Indiana does not lend itself to any considerable water-power development, so the State must depend upon its large coal supply for power. The total installed generating capacity is 320,000 kw., being steam units with few exceptions. A water survey of the State shows power available for hydro-electric development as 126,000 hp., considerable part of which lies along the drainage area of the Wabash and Ohio rivers. The steam plants of the State are interconnected by adequate transmission systems radiating from Indianapolis.

The total number of steam properties within the State is 185, as compared with 224 in Illinois. The principal companies operating these former properties are: The Union Traction Co. of Indiana, the Indiana General Service Co., Interstate Public Service Co., Ft. Wayne & Northern Indiana Traction Co., Northern Indiana Gas & Electric Co., Indianapolis Light, Heat & Power Co., Indiana Railways & Light Co., Terre Haute Traction & Light Co.

One of the large manufacturing districts is served by the Northern Indiana Gas & Electric Co. at Michigan City, Hammond and East Chicago.

The one hydro-electric system of importance in the State is the property of the Indiana & Michigan Electric Co., with dams located at Elkhart, Ind., Berrien Springs and Buchanan, Mich. The transmission line serves South Bend, Michigan City and intermediate substations. The system is also supplied with power from steam plants at South Bend and Elkhart. Total water-power capacity is 20,000 hp. installed.

INTERCONNECTED TRANSMISSION LINES OF ILLINOIS

The Need for Research in the Non-Metallic Mineral Field*

Economic Importance of the Industry of Inorganic Non-Metallic Minerals—Need of Investigations and Engineering Studies on Their Value and Adaptability to Other Industries—Influence of the Non-Metallics Upon the Daily Life of a Community

BY RAYMOND B. LADOO†

INDUSTRIAL problems brought out by the war and by the reversion from war to peace conditions have made necessary many changes of practice and methods which will result in the conservation of material resources, energy, efficiency and man power. Research is always necessary, but to-day it is particularly important. But our programs of research also need revision. In the mining and mineral industries a survey of the whole field is necessary to determine what fields have been covered, what fields should be covered, and what are the present problems in such fields.

All mining and metallurgical industries can be divided into three well defined groups: (1), the metal and alloy group; (2), the organic non-metallic group; and (3), the inorganic non-metallic group. The first group comprises the major and minor metals and their alloys. The organic non-metallic group includes coal, lignite, peat, petroleum, natural gas and other natural fuels. While it may be questionable if petroleum is of organic origin, for the purposes of research and investigation it logically falls within this group. The inorganic non-metallic group includes granite, sandstone, limestone, marble, slate and other structural stones; sand and gravel; limestone, dolomite, fluorspar and other fluxing stone; cement; clays and clay products; glass sand and

The economic importance of this group is great, and it is worthy of careful study.

Most of the minerals of this group are used as mined with but little modification, and their physical properties are preserved without change. Noteworthy exceptions to this are the manufacture of glass from glass sand, and cement from limestone and clay or shale. In the latter industries, the manufacture of glass and cement corresponds to the smelting or other metallurgical treatment of the metals. But in most instances the value or suitability of a non-metallic mineral depends upon preserving intact, in the finished products, its original physical and chemical characteristics. Thus the fibrous structure of asbestos, the platy structure of mica and the soft, white, greasy characteristics of talc are essential to their use.

IMPORTANCE OF GROUP NOT GENERALLY RECOGNIZED

The importance of this non-metallic group and its proper place in mining investigation and literature have not been generally recognized. Quarrying is really but a special form of open-pit mining. Moreover, many non-metallic minerals are produced by underground mining methods. Methods of milling are strictly comparable with those used in the treatment of the metallic ores, and the "metallurgy" of such non-metals as glass sand and cement materials makes use of machinery, furnaces and methods similar to those used in true metallurgy. The largest screening and milling plants in the world are to be found in the sand, gravel and crushed rock industries. The largest gyratory crusher ever built has recently been installed at a limestone plant in Michigan, and likewise one of the largest, if not the largest, washing plant in the world is in operation in Michigan, washing limestone used as fluxing stone in the smelting of iron in the blast-furnace.

There are probably several reasons for this comparative oblivion. The intrinsic value of the crude materials in the ground is often low in comparison to that of the metals. Such materials as clay, sand, limestone and soapstone do not appeal to the average miner or prospector as do the metals. They are not surrounded with the glamour and romance that has made the search for the metals full of interest since prehistoric times. Another reason is that the value of many non-metallics depends largely upon collateral conditions, such as local demand, proximity of markets, freight rates, size and availability of deposits, rather than on intrinsic value. Copper or silver ores have a definite value depending upon their metal content, and the prospector does not have to consider how to market his product. Clay, talc, limestone and mica require a knowledge of market possibilities, and thus the needs for definite knowledge and engineering and business ability are even greater. The winning of most non-metallics has seemed easy compared to that of metals; and consequently little atten-

glass; feldspar, flint, and other ceramic materials; salt and salines; phosphate rock, potash salts and other fertilizer materials; emery, corundum and other abrasives; magnesite; asbestos; mica; chalk, bauxite; talc and soapstone; gypsum; fuller's earth; graphite, etc.

Research in the metal group has been important for several decades. The need for research in the organic non-metallic group has been emphasized during the war and, while much work remains to be done, this field is now receiving much attention. The inorganic non-metallic group, however, has received but comparative little attention by mining and metallurgical engineers.

tion has been paid to these subjects by the engineer. In the past many non-metallic mines and quarries have been started and run in a small, inefficient way by farmers or others as a side line. They have not, as a rule, until recently been considered as engineering problems of a magnitude comparable with metal mining operations, or as business propositions.

ECONOMIC IMPORTANCE OF THIS MINERAL GROUP

That this mineral group is of great economic importance is shown by the following statistics compiled for the year 1916 by the U. S. Geological Survey in which the figures have been changed to round numbers. The total value of all mineral commodities was about \$3,500,000,000. The combined value of groups 1 and 2, or the metal group and the organic non-metallic group, was about \$3,000,000,000, while the value of group 3, the inorganic non-metallic group, was about \$500,000,000. Thus there was a ratio of 6 to 1 between the combined

METHOD OF MOVING A CHANNEUSING MACHINE WITH A
DERRICK, BEDFORD, IND.

values of groups 1 and 2 and group 3. If all of the minerals and metals are arranged in descending order of value, clay stands third in the list, being only preceded by coal, iron and steel.

Evidence of the small amount of work already done in this group may be obtained by an examination of the shelves or index of a large mining library or by consulting volumes of the transactions of any large mining and metallurgical society, such as the American Institute of Mining and Metallurgical Engineers. It is safe to say that there are at least fifty volumes relating to the metallics to one relating to the non-metallics. It is probable that, taking all mining and mineral literature, research and investigations together, this discrepancy would be far greater. There are a hundred consulting engineers in the one group to one in the other. Our technical mining and metallurgical societies

ANOTHER VIEW OF HURON PORTLAND CEMENT CO.
QUARRY, ALPENA, MICH.

contain few members interested primarily in the non-metallics, and their publications contain very few references to technical work in this group. Research and investigation in this group would improve methods of mining and milling, increase safety and efficiency, decrease waste, find new uses and wider and more varied markets, make available large deposits of valuable minerals not now workable and improve the preparation of many domestic products so that we might be independent of foreign sources of supply.

INFLUENCE OF THE NON-METALLICS ON DAILY LIFE

Let us consider for a moment the influence of the non-metallics upon the daily life of the community. All large buildings are preponderantly non-metallic. They are built of stone or brick, tile, terra-cotta or concrete. Highways are stone, brick, concrete or asphalt and crushed rock. Large dams, dry docks, piers, breakwaters, bridges or bridge foundations, fortifications, subways and lighthouses are all built wholly or in major part of non-metallic mineral products. Water-distributing systems use concrete in the construction of dams, and sand and gravel in filtration plants; sewerage systems use clay sewer pipe. Metallurgical industries use limestone, dolomite and fluorspar fluxes; silica, clay, magnesite, dolomite, chromite and graphite refractories; abrasives, minerals, pigments, molding and filtering sand, and asbestos, and magnesite heat insulations. In almost every home are tiled bath rooms with their sanitary porcelain fixtures, living rooms with their marble or tile mantels, and tile, brick or stone fireplaces, glass mirrors, windows, lighting fixtures and glass-protected pictures, dining rooms with all their china, porcelain and glassware, the enamel on cooking

GENERAL VIEW OF THE BEDFORD, IND., LIMESTONE QUARRIES

utensils and sinks, asbestos mats, mica lamp chimneys and mica insulations in electric flatirons, basements with concrete floors, with their furnaces and pipes protected by asbestos and magnesia pipe-coverings and cements, and laundries with soapstone sinks and tubs. There is not a phase of our everyday life that is not touched directly or indirectly by the non-metallic minerals. Even the newspapers and magazines which we read use clay, talc, gypsum, chalk or other minerals as fillers and coatings. Rubber automobile tires contain talc, clay, magnesite or chalk as a filler; brake linings are of asbestos.

The importance of many of these things is often unrealized until supplies are suddenly cut off. During the war imports of Grecian and Austrian magnesite, Ceylon and Madagascar graphite, Italian, French and German talc, English fuller's earth, English china clay, German potash salts and other vital mineral commodities were cut off entirely or greatly reduced. Immediately our industries felt the loss and our war activities would have been crippled seriously had not domestic sources been immediately developed and by research adapted to our needs. If we had not possessed large resources of common salt, our great production of chlorine and other asphyxiating gases would have been impossible.

FIELD A WIDE ONE

The problems and needs for research are as great in the non-metallic fields as in the metallic. Quarrying seems simple, but there is a large and almost untrodden field here for the application of modern engineering and mining principles. The methods of mining, milling and grading of talc and the mining, trimming and grading of mica offer fields for great improvement. It has been stated that domestic mica could fill all of the needs of this country, if properly trimmed and graded, yet over 60 per cent of the mica used in the country is imported. There are vast resources of high-grade clays in this country, but owing to improper methods of mining, washing, grading and blending, they are not considered satisfactory for our best porcelain and paper, and a very large amount of such clay is imported from England.

The chemical and physical properties of the metals have been accurately measured and standard tests of strength, composition and purity have been devised. Most metallic products are now purchased on specification, and checked up by standard tests. It is of interest to note that very few standard tests have been devised for the non-metallic minerals or their products, and few specifications are used in purchasing. Each producer makes certain grades which are in accord with his own

ideas, but practically no two producers in certain industries offer the same or comparable grades. Consumers do not even know what grades are best suited to their needs. This creates confusion and dissatisfaction, and in the long run greatly injures the producer. For example, a papermaker may be induced to try talc as a substitute for English clay as a filler. The grade of talc which he tries may be totally unsuited to his uses and prove a failure. That papermaker then concludes that the use of talc in his paper is impossible and he condemns talc in general. A different grade of talc, intelligently selected from standard specifications, might have been found far superior to English clay. The lack of standardization of caustic magnesite for the plastic flooring industry has caused great dissatisfaction with California magnesite for this purpose. Doubtless this has been one of the factors in the lack of development of California magnesite for use in the flooring industry.

Our non-metallic minerals are more valuable than is ordinarily supposed. English china clay sells for over \$30 per ton, Italian and French talc for \$60 per ton, and asbestos No. 1 crude for over \$1,500 per ton. Even fluxing limestone sold for \$2.50 per ton or more in certain sections during the war. These values compared favorably with those of many of our metallic ores.

It has been argued that the mining problems in the non-metallics are the same as those in metallics, and that a consulting engineer experienced only in metallic ore mining can successfully enter the non-metallic field. So he can, if he is willing to make a detailed study of the new problems involved. But the non-metallic problems are usually very different from those in metallics.

INTERIOR VIEW OF A GEORGIA MARBLE QUARRY

MILL NO. 3, EASTERN TALC CO., ROCHESTER, VT.

For example, in the quarrying of structural stone, the shape and size of the finished blocks are important. Fault and joint planes, color and grain, hardness and texture must be considered. The machinery involved is different. Few metal-mining engineers are familiar with the use of channeling machines or sawing, grinding and polishing machinery. In mining talc to be used for ground talc, grit must be excluded and iron-bearing surface water must not be allowed to discolor the talc. If the talc is to be sawed into crayons, or used for "lava" (baked talc used for gas burner tips and electrical insulation), it must be removed underground in large, sound blocks. In the milling of asbestos, the ore must not be left too long in a "breaker," or the fibers will be broken. In the mining of mica, large plates must not be broken by drilling or blasting. The white color of kaolin must not be spoiled by surface water or a mixture with iron-bearing clay or overburden. In preparing magnesite, care must be taken to exclude all dolomite or other lime-bearing carbonate.

In the underground mining of limestone, the value of the product is such that very little timbering can be afforded and methods of mining without timber must be used. Few metal-mining engineers appreciate the great difference between the two fields, and they are apt to minimize the essential distinctions, or to overlook the importance of this field entirely. These problems are often very difficult of solution, and call for the use of the best engineering skill, backed up by experience.

Another field of research in this group is that of determining accurately the physical and chemical properties of many minerals, looking toward the discovery of new uses. A good example of this is the mineral talc. Contrary to the impression which prevails in the minds of many, the principal use of talc is not for talcum powder, but as a filler for paper. Probably 80 per cent of the talc consumed in this country goes into the manu-

facture of paper. But there are many other important uses, among which are the roofing, paint and rubber industries, foundry facings, fillers for cotton cloth, "lava" gas tips and electric insulation. Over forty uses for talc are now known, many of which were developed during the last few years. But these uses could be greatly expanded if all of the chemical and physical properties of talc were studied and tabulated. For example, the colloidal properties of finely ground talc should be studied to determine further possibilities of talc as a lubricant in a water or oil suspension. The hardening of talc under heat is utilized in the manufacture of "lava," and research might extend this use. The presence of grit and dark color in some ground talcs is objectionable for many uses. These objectionable points might be eliminated by better methods of grinding and grading or by chemical treatment.

The subject of clay is one upon which much has been written, though there is little of permanent value. Of the best methods of mining and washing clays very little is known, and practically nothing has been published.

Within the last few years the producers of non-metallic minerals have begun to realize the importance of their industries and have awakened to the possibilities of expansion. Producers' associations have been formed

TRAVELING CRANE AT VERMONT MARBLE CO. STOCK PILE, WEST RUTLAND

with energetic technical and publicity committees. Advertising campaigns aimed to educate the public and popularize their products have been inaugurated, and as a result great progress has been made. Many persons who had never heard of magnesite a few years ago are now using magnesite pipe coverings in response to the slogan, "Let 85 per Cent Magnesite Defend Your Steam." A good beginning has been made and great expansion in this group of minerals seems inevitable.

SUMMARY

1. The great economic importance of the inorganic non-metallic minerals cannot be denied.
2. Literature, research and investigations in this field have been very meager and unsatisfactory.
3. The intrinsic values of the individual minerals are large enough to attract the best engineering and business talent.
4. Mining and milling problems in the non-metallics are different from those in metallics and often are not appreciated by metal mining engineers.
5. A comparatively untrodden field lies open for consulting mining engineers and industrial chemists.
6. All present tendencies indicate a period of great expansion in this field in the near future.

CHANNELING MACHINES AT WORK, BEDFORD, IND.

Glucinum

An Introduction Intended to Encourage the Metallurgical and Chemical Development of the Industry of Glucinum, Its Alloys and Salts—Abundance of the Glucinum Minerals—Description of Some Relatively Successful Methods Employed for the Production of Glucinum Metal

By J. S. NEGRU

THE minerals of glucinum have been, and to some extent still are, considered useful only as precious stones for ornamental purposes, but only an infinitesimal quantity of these minerals is found to be of sufficient purity and beauty of color to make them valuable as ornaments. The minerals of lower quality were, and still are, practically useless, and their mining is neglected. There is an abundance of glucinum minerals in the United States and elsewhere, some of them in crystals weighing about 60 lb. (gadolinite, Texas) and even about 2900 lb. (beryl, New Hampshire). According to J. H. L. Vogt¹ between 0.01 per cent and 0.001 per cent of the entire earth's crust is glucinum. The progress realized in industrial chemistry has opened new aspects as to the value of these minerals for their glucinum content.

VAUQUELIN FIRST TO DISCOVER EXISTENCE OF GLUCINUM

In 1797 the mineralogist Haüy, having found that the minerals beryl and emerald have the same physical structure, hardness and specific gravity, entrusted L. N. Vauquelin with the work of determining whether these minerals were also of identical chemical composition. Vauquelin, besides proving that they are identical chemically, also discovered that they contain an oxide which until then was considered to be alumina, but which he separated from the alumina by the precipitation occurring when the caustic potash solution of the hydrates is concentrated by boiling. He studied this new product and assigned to it many distinctive properties, of which the most characteristic are: Its salts are sweet and lightly astringent; soluble in dilute ammonium carbonate; insoluble in ammonia; does not form alums; absorbs $\frac{1}{2}$ of its weight of carbon dioxide; decomposes salts of alumina. He has given to the oxide a place between alumina and magnesia. Due to the fact that the salts of this new oxide are sweet, it was named glucina.²

Humphry Davy attempted to reduce glucina with potassium vapors, but without success. He then fused glucina with iron filings and potassium in a clay crucible, dissolved the fused mass in water and obtained a residue of a semi-malleable mass. This was in reality a glucinum-iron alloy.³

F. Wöhler in 1827 was the first to succeed in isolating glucinum metal. He worked on the chloride obtained by mixing glucinum hydroxide with carbon and heating the mixture to red heat in a current of chlorine gas. He placed in a platinum crucible a layer of potassium, then the glucinum chloride and then another layer of potassium, and heated to fusion. The fused mass was thrown into a beaker of water; the potassium salt

formed was dissolved, and there was left a dark-gray residue which when washed, dried and burnished presented a metallic luster.⁴ Bussy in France prepared a similar product almost simultaneously with Wöhler, and by the same method. The product was an impure glucinum. Subsequent work by others led to the separation of a 99.8 per cent pure glucinum.

Up to the present the only methods by which the metal is extracted from its minerals are based on the obtainment of its haloids directly or by subsequent treatments, and by reducing these haloids mainly with potassium or sodium, or by electrolyzing a solution of a double chloride, bromide or fluoride of glucinum. These methods, although already employed on a quasi-industrial scale, render the cost of glucinum quite prohibitive. The direct reduction of glucina has not yet been made on a practical scale, but when this is realized the special properties of the metal, combined with its reduced cost, will contribute to its becoming one of the most valuable metals in chemical and other industries.

USES OF GLUCINUM

Glucinum possesses properties which will make it useful for the manufacture of special electrical and other scientific instruments and apparatus; its organic and inorganic salts have, some at least, useful pharmaceutical properties; its alloys, especially the glucinum-copper alloys, are already known to possess important properties, and their more extensive use is only a matter of lower cost. The synthetic preparation of pure precious stones for ornamental purposes, some of which have already been produced, is another field for the industrial use of glucinum and its salts.

Glucinum Minerals

The metal glucinum is not found in a native state, but is present in a great number of granitic rocks in the form of aluminates, silicates, phosphates, borates, etc. The minerals of glucinum which are already known to occur in the United States in quantities sufficient to permit their economic use are:

Bertrandite. A glucinum silicate of the composition $4\text{GlO} \cdot 2\text{SiO}_2 \cdot \text{H}_2\text{O}$ (50.3 per cent SiO_2 , 42.1 per cent GlO , 7.6 per cent H_2O). It is found in Bohemia, France and in the United States (Colorado, Maine, Virginia). Colorado: Mount Antero, Chaffee County; Maine: Stoneham, Oxford County; Virginia: Amelia Court House, Amelia County.

Beryl. A glucinum-aluminum silicate of the composition $3\text{GlO} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{SiO}_2$ (67 per cent SiO_2 , 19 per cent Al_2O_3 , 14 per cent GlO). It is found in Austria, Bo-

hemia, Brazil, Colombia, Cornwall, Island of Elba, Egypt, Finland, France, India, Ireland, Madagascar, New South Wales, Norway, Peru, Scotland, Siberia, Sweden and the United States (Alabama, California, Colorado, Connecticut, Georgia, Maine, Massachusetts, New Hampshire, New Mexico, North Carolina, Pennsylvania, South Carolina, South Dakota, Utah, Virginia).

Alabama—Near Rockford and Hissop, Coosa County.

California—Riverside County: Coahuila and near Hemet; San Diego County: Pala, Rincon, Mesa Grande, Ramona, and in the Polomar Mts. 9 miles southeast of Pala; Tuolumne County: Jamestown.

Colorado—Boulder County: near Glendale; Chaffee County: near top of Mount Antero; Clear Creek County: Georgetown; Fremont County: at East Gulch, 6½ miles north of Texas Creek; Jefferson County: near Creswell; Park County: Buffalo Mt.

Connecticut—Fairfield County: Branchville; Litchfield County: 6½ miles north of New Milford; Middlesex County: Middletown, Portland, Chatham and Hadam; New Haven County: Southford Quarry.

Georgia—Rabun County: Beck Beryl Mines, 7 miles east of Clayton.

Maine—Kennebec County: Winslow; Oxford County: Albany, Newry, Paris, Greenwood, Stoneham, Peru, Hebron (Cæsium beryl), Buckfield (Cæsium beryl); Sagadahoc County: Topsham; Androscoggin County: Auburn, Poland (Cæium beryl); Hancock County: Catharine Hill.

Massachusetts—Worcester County: Royalston; Franklin County: Northfield; Hampden County: Blandford; Hampshire County: Chesterfield, Goshen, Norwich.

New Hampshire—Cheshire County: Sullivan, Alstead, Roxbury; Grafton County: near Orange, near Grafton, Wentworth, Alexandria; Merrimack County: 2 miles west of Danbury; Sullivan County: near South Acworth.

New Mexico—Santa Fé County: near Santa Fé.

North Carolina—Alexander County: near Hiddenite; Burke County: near Burkmont; Jackson County: south of Cashiers; Macon County: at head of Tennessee Creek; Mitchell County: Wiseman and other mica mines; Yancey County: Ray and other mica mines.

Pennsylvania—Chester County: near Northrop and Unionville; Delaware County: Leipsville, Chester, near Media; Philadelphia County: Fairmont Park, Germantown, Logan, Mount Airy, Shawmont.

South Carolina—Anderson County: along the Anderson Spartanburg zone.

South Dakota—Custer County; Pennington County: near Keystone.

Utah—Tooele County: about 35 miles southwest of Simpson Springs, Ibapah Mountain.

Virginia—Amelia County: Amelia mica mine; Henry County: near Axton; Rockbridge County: in Irish Creek area.

Beryllonite. A sodium-glucinum phosphate of the composition $\text{Na}_2\text{P}_2\text{O}_7 \cdot \text{Gl}_2\text{P}_2\text{O}_7$ (55.9 per cent P_2O_5 , 19.7 per cent GIO , 24.4 per cent Na_2O). It is found in the United States at Stoneham, Oxford County, Maine.

Chrysoberyl. A glucinum-aluminium oxide of the composition $\text{GIO} \cdot \text{Al}_2\text{O}_3$ (80.2 per cent Al_2O_3 , 19.8 per cent

GIO). It is found in Brazil, Ceylon, Ireland, Moravia, Siberia and the United States (Colorado, Connecticut, Maine, New Hampshire and New York).

Colorado—6 miles west of Sedalia, Fremont County. Connecticut—Haddam, Middlesex County.

Maine—Newry and Stoneham, Oxford County.

New Hampshire—New Orange Summit, Grafton County.

New York—Greenfield, Saratoga County.

Danailite.—A complex mineral of the composition $(\text{Gl}, \text{Fe}, \text{Zn}, \text{Mn})_2\text{Si}_2\text{O}_7\text{S}$ with about 14 per cent GIO . It is found in the United States (Colorado, Massachusetts, New Hampshire).

Colorado—West Cheyenne Canyon, El Paso County.

Massachusetts—Essex County: Rockport, Cape Ann, Gloucester.

New Hampshire—Bartlett.

Gadolinite. A complex silicate of glucinum, iron and yttrium, of the composition $2\text{GIO} \cdot \text{FeO} \cdot 2\text{Y}_2\text{O}_3 \cdot 2\text{SiO}_2$ (23.9 per cent SiO_2 , 51.8 per cent Y_2O_3 , 14.3 per cent FeO , 10 per cent GIO). It is found in Greenland, Ireland, Norway, Silesia, Sweden and the United States (Arizona, Colorado, Texas).

Arizona—Mohave County: In cliffs, 30 miles south of Hackberry, and near Kingman, about 6 miles west of Chin Lee Valley and 2 to 4 miles south of the Utah line.

Colorado—Douglas County: Devil's Head Mountain; Washington County: Akrcn.

Texas—Burnett County; Llano County: Baringer Hill.⁵

Helvite. A complex silicate of the composition $(\text{Mn}, \text{Fe})_3\text{S}_3(\text{Gl}, \text{Mn}, \text{Fe})_2\text{SiO}_7$ with about 13.5 per cent GIO . It is found in Finland, Hungary, Norway, Saxony and the United States (near Amelia Court House, Amelia County, Virginia).

Herderite. A fluophosphate of calcium and glucinum of the composition $(\text{CaF})\text{GIPO}_4$ (43.8 per cent P_2O_5 , 15.4 per cent GIO , 34.6 per cent CaO , 5.9 per cent F). It is found in Saxony and the United States (Maine: Hebron and Stoneham, Oxford County, and Auburn, Androscoggin County).

Phenacite. A glucinum orthosilicate of the composition $2\text{GIO} \cdot \text{SiO}_2$ (54.45 per cent SiO_2 , 45.55 per cent GIO). It is found in the Urals (near Ekaterinsburg), France, Mexico (near Durango), Switzerland and the United States (Colorado, Maine, Virginia).

Colorado—Chaffee County: Mount Antero and Devil's Head; El Paso County: Crystal Park, 2 miles southwest of Manitou; Teller County: Topaz, Butte, near Florissant, and at Cripple Creek in the Gold King Mine.

Maine—Near Stoneham, Oxford County.

Virginia—Amelia Court House, Amelia County.

Other important glucinum minerals, which have not yet been located in the United States, are:

Euclase. A glucinum-aluminum silicate of the composition $2\text{GIO} \cdot 2\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$ (41.3 per cent SiO_2 , 35.2 per cent Al_2O_3 , 17.3 per cent GIO , 6.2 per cent H_2O). It is found in Brazil (Province of Minas Ceraes), Ural (Orenburg District) and in the Austrian Alps.

Eudidymite. A glucinum-sodium silicate of the composition $\text{H}_2\text{O} \cdot \text{Na}_2\text{O} \cdot 2\text{GIO} \cdot 6\text{SiO}_2$ (73.4 per cent SiO_2 , 10.2 per cent GIO , 12.7 per cent Na_2O , 3.7 per cent H_2O). It is found in southern Norway, near Langesund fiord.

⁵Here are found crystals of beryl weighing up to 2900 lb.

⁶Here are found crystals of gadolinite weighing up to 60 lb. The Stoneham mineral is also called *glocline*.

Hambergite. A glaucinum borate of the composition $4\text{GIO.B}_2\text{O}_3.11\text{H}_2\text{O}$ (53.25 per cent GIO, 36.72 per cent B_2O_3 , 10.03 per cent H_2O). It is found in southern Norway, near Langesund fiord.

Leucophane. A complex silicate of the composition $\text{NaF.3GIO.3CaO.5SiO}_2$, with 10.3 per cent GIO. It is found in the southern part of Norway, near Langesund fiord.

Meliphanite. A complex silicate, somewhat similar to leucophane, of the composition $\text{NaF.2GIO.2CaO.3SiO}_2$, with 13.1 per cent GIO. It is found in Norway, near Langesund fiord.

Trimerite. A complex silicate of the composition $(\text{Mn,Ca})_2\text{SiO}_4.\text{GIO}_2$, with 16.6 per cent GIO. It is found in Sweden, at Vermland.

Glaucinum is also found in some natural waters, monazite sand, and some aluminous schists.

Treatment of Glaucinum Minerals for Glucina

METHOD OF VAUQUELIN⁴

The mineral (beryl) is crushed and heated. The cooled mass is pulverized and mixed intimately with 3 parts of its weight of caustic potash, and the mixture is fused. The mass obtained is cooled and dissolved in water; filter to separate the silica. The filtrate is treated with an excess of caustic potash solution and boiled until a precipitate is obtained which contains the hydroxides of all the glaucinum and some of aluminum. The precipitate is filtered off and dissolved with hydrochloric acid and reprecipitated with potassium carbonate. This precipitate is filtered off and dissolved with sulphuric acid, and potash is added to the solution, when aluminum separates in the form of crystallized alum. Filter. The filtrate, which has a very sweet taste, is diluted with water and an excess of ammonium carbonate is added. Only the glaucinum salt remains in solution. Filter. The filtrate is concentrated by boiling until a precipitate is obtained, which is washed and dried, yielding basic glaucinum carbonate. This when calcined yields glucina (GIO).

METHOD OF DEBRAY⁵

The mineral (beryl) is pulverized and mixed with half its weight of powdered quicklime. The mixture is fused in clay crucibles. The glass obtained is powdered and treated first with dilute nitric acid, then with concentrated nitric acid, with continuous agitation till it is reduced to a homogeneous jelly. This is evaporated to dryness and calcined sufficiently to decompose the nitrates of aluminum, glaucinum, iron and also a small portion of the nitrate of calcium. The residue, which consists of silica, alumina, glucina, iron sesquioxide, calcium nitrate and a little lime, is boiled with an ammonium chloride solution, when the calcium nitrate and the lime are dissolved with evolution of ammonia. (If there is no evolution of ammonia it indicates that the calcining has not been carried out sufficiently, when it is necessary to calcine again and re-treat as above.) Filter. Pour the filtrate into an excess of an ammoniacal solution of ammonium carbonate. Allow to stand for 8 days, when all the glaucinum and a small amount of iron salts are dissolved. Add a little ammonium sulphide to precipitate the iron completely. Filter. The filtrate contains

only the glaucinum salt. Concentrate the solution by boiling, when the ammonium carbonate is decomposed with the formation of a basic glaucinum carbonate which separates as a white powder precipitate. Filter. This precipitate washed, dried and calcined yields glucina.

METHOD OF SCHEFFER⁶

This method is based on the fact that when metallic zinc is introduced into a solution of aluminum sulphate, zinc sulphate is formed along with basic sulphate of aluminum which precipitates. This precipitation is complete in a dilute solution. The glaucinum sulphate treated in an analogous manner is decomposed with the formation of dibasic sulphate which remains completely dissolved.

The mineral (beryl) is powdered and mixed with fluorspar. The mixture is digested with sulphuric acid at a gentle heat (about 200 deg. C.) and ultimately heated to dull red to expel the silicon fluoride and the excess of sulphuric acid. The residue is dissolved in water acidulated with sulphuric acid. In order to remove the greater part of aluminum add to the solution potassium sulphate or ammonium sulphate, thus forming alums which crystallize out. Filter. The filtrate is greatly diluted, and metallic zinc is added. Allow to stand 2 to 3 days. Heat and filter. To the filtrate add a quantity of potassium sulphate proportional to the amount of zinc used (1.4 parts K_2SO_4 for 1 part Zn) to form with the sulphate of zinc a double salt which crystallizes out. To remove the rest of the zinc add to the solution an excess of sodium acetate and pass a current of hydrogen sulphide. Filter. The filtrate is treated with ammonia and ammonium sulphide to remove the iron. Filter, and neutralize the filtrate with ammonia and add an excess of ammonium carbonate. Filter and concentrate by boiling, when a precipitate will be obtained. Filter. The residue washed and dried yields the basic glaucinum carbonate. This when calcined yields glucina (GIO).

METHOD OF GIBSON⁷

This method is based on the principle that ammonium-hydrogen fluoride effects the complete decomposition of beryl at a relatively low temperature, even when the mineral is only coarsely powdered. The crude ammonium-hydrogen fluoride employed is prepared by neutralizing commercial hydrofluoric acid in a leaden vessel with ammonium carbonate, then a quantity of hydrofluoric acid equal to the quantity taken in the first place is added, the solution concentrated by boiling, and on cooling the double fluoride crystallizes out.

The mineral (beryl) is coarsely ground and mixed thoroughly in a large iron pot with 6 parts of ammonium-hydrogen fluoride. The mixture is liquefied and boiled with continuous stirring until it becomes a thick mass and dense white fumes (ammonium fluosilicate) are given off. The mass is cooled, powdered roughly, boiled with water for several hours, allowed to settle and filtered. The residue is re-treated as above and filtered. Combine the filtrates, and then evaporate to dryness. The fluorides are converted into sulphates, by treating with concentrated sulphuric acid. Heat until a partial decomposition of the sulphates has taken

place. Digest with water and filter. Add to the filtrate nitric acid to oxidize the iron and pour the solution in small portions at a time into an excess of ammonium sesquicarbonate with frequent agitation. The aluminum salt and the bulk of the iron are precipitated and only the glucinum salt and a small quantity of iron remain in solution. Filter. To remove the last traces of iron from the filtrate add mercuric chloride and ammonium sulphide and filter. The filtrate is neutralized with ammonia and treated with an excess of ammonium carbonate. Only the glucinum salt remains in solution. (If some mercury passes over it will be eliminated in the subsequent calcining.) Filter. The filtrate is boiled until basic glucinum carbonate separates out, which is washed, dried, and ignited to yield glucina (GIO).

METHODS OF LEBEAU¹²

The mineral (beryl) is mixed with two parts of calcium fluoride, and the mixture fused in a graphite crucible. The fused mass is poured into water, thus yielding a porous material which is easily pulverized. The powder is placed in a stoneware vessel and attacked with sulphuric acid in the cold, avoiding excessive heat. Silicon fluoride escapes. When this reaction is complete, heat on a sand bath until white fumes of sulphuric acid appear. Now throw the mass by small portions into water, when the sulphates of aluminum, glucinum and iron are dissolved, and there remains a deposit of calcium sulphate. Decant. The precipitate is washed and filtered and the solutions are concentrated. The excess of acid is then partially saturated with potassium carbonate, and the liquid is allowed to cool, when the greatest part of the aluminum separates in the form of alum. Filter. The filtrate is saturated with ammonia with the further addition of an excess of ammonium carbonate. Allow to stand for a few days with frequent stirring. Filter. The filtrate on ebullition deposits an impure glucinum-ammonium carbonate. Filter. The residue is redissolved in nitric acid. Dilute, and add a little potassium ferrocyanide, which throws down all the iron. Filter. (The last precipitation is avoided if instead of potassium ferrocyanide ammonium ferrocyanide is used and the iron separated by H_2S .) The filtrate free of iron is treated with ammonia; leave stand 3 or 4 days; the supernatant liquor is decanted and replaced by a concentrated solution of ammonium carbonate, which slowly dissolves the glucinum salt, leaving a slight white deposit of aluminum hydroxide. Filter. Boil the solution, the precipitate formed is carefully washed and dissolved in nitric acid. Evaporate to dryness and ignite. The product which is obtained is pure glucina (GIO).

Lebeau also used an electric furnace.¹³ Instead of fusing a mixture of the mineral with calcium fluoride in an air furnace he melted and boiled the mineral (beryl) by the heat of an electric furnace. The finely powdered mineral is mixed with its own weight of clean coke. The mixture is heated in an electric furnace for $1\frac{1}{2}$ hr. with a current of 1500 amp. Abundant vapors of pure silica are driven off, leaving a fused substance which consists of a mixture of aluminum carbide, glucinum carbide, iron silicide and carbon silicide. By subjecting the mass to weathering conditions it disintegrates. The disintegrated mass contains the aluminum and glucinum partly as hydrates and partly as carbides, which are easily attacked by acids. By using hydro-

fluoric acid and sulphuric acid the silica is expelled as silicon fluoride, and the residue, which consists of the sulphates of aluminum, glucinum and iron, is treated as above.

METHOD OF WARREN¹⁴

The mineral (beryl) is powdered and incorporated thoroughly with four times its weight of sodium carbonate. The mixture is fused for 3 hr. at the highest temperature of a powerful blast-furnace. Cool the melt, dissolve by supersaturated steam and an excess of hydrochloric acid. Evaporate to dryness, take up with water and filter off the silica. The filtrate is freed of its iron content and the precipitate is filtered off. The filtrate is rendered alkaline by means of an excess of sodium carbonate, and heated with an excess of gaseous sulphurous acid in which both the alumina and glucina dissolve. The solution is heated to boiling, when aluminum hydroxide is precipitated in a granular form instead of the tedious gelatinous deposit obtained when using ammonia. Filter. Add to the filtrate an excess of ammonium carbonate. The solution is concentrated by boiling, when basic glucinum carbonate separates out as a white granular powder. Filter the residue, wash, dry and calcine for glucina, or keep as carbonate for further treatment. (See page 358.)

METHOD OF WYROUBOFF¹⁵

In examining various compounds of glucinum, Wyrouboff has found that the oxalate $2GiC_2O_4 \cdot 3K_2C_2O_4$ is only sparingly soluble; thus at 15 deg. C. 100 parts of water dissolve only 1.4 parts, and the solubility does not increase appreciably with the temperature, whereas at the same temperature the oxalates of aluminum, iron and chromium are completely soluble in only 2 to 3 parts by weight of water. He has made use of this property for a process to treat glucinum minerals for glucina.

The mineral is attacked with potassium hydrate, the silica separated in the usual way, the solution of chlorides evaporated to a small volume and treated with a concentrated solution of potassium oxalate. After a short time of standing a crystalline precipitate of oxalates is formed. Decant. The residue is treated with a small quantity of water, when only the glucinum salt remains undissolved. Filter the residues, dry and calcine to glucina, or preserve as oxalate and use as a starting product for other glucinum salts. To avoid the presence of acids during the operation, as the oxalate of glucinum is very soluble in dilute acids, it is best to neutralize the solution with an alkali after adding the potassium oxalate.

METHODS OF POLLOK¹⁶

The mineral (beryl) is finely powdered and mixed with its own weight of caustic soda. The mixture is fused; the cooled mass is pulverized and treated with strong hydrochloric acid with constant stirring. The heat generated by the reaction brings the whole mass to the boiling point without the necessity of external heat. Allow to settle for one day. Decant, add more hydrochloric acid and water, and boil with steam. Allow to settle, siphon the solution and throw the silica on a linen filter and wash. Treat the whole of the solution

with ammonia, re-dissolve the precipitate with hydrochloric acid and saturate the solution with hydrochloric acid gas, thus precipitating nearly all the aluminum as chloride and leaving all the glucinum and iron in solution. Filter. Concentrate the filtrate by boiling until it becomes of syrupy consistency, and add it by small quantities at a time to a saturated solution of ammonium carbonate with repeated stirring. Only the glucinum salt and a little iron remain in solution. Treat with ammonium sulphide to separate the iron, allow to stand for 2 days and filter. The filtrate free of aluminum and iron is concentrated by boiling to about half its volume, when all the glucinum is precipitated in the form of basic glucinum carbonate, which when washed, dried and calcined yields glucina.

By another method of Pollok the powdered mineral is mixed with caustic potash and fused. The cooled mass is pulverized and treated with dilute sulphuric acid and well boiled with steam. Filter to separate the silica. The filtrate is evaporated to the crystallizing point, allowed to cool and stand for one day. The alum crystals formed are drained off. Re-evaporate the filtrate and repeat the process until a portion of the mother liquor, when poured into an excess of ammonium carbonate, gives a precipitate that completely re-dissolves on shaking up. The whole of the liquors containing all the glucinum as sulphate and some impurities is poured by small quantities at a time into a saturated solution of ammonium carbonate with repeated stirring. Add ammonium sulphide to separate the iron. Filter. The filtrate containing only the glucinum salt is treated as in the first method.

By still another method of Pollok the powdered mineral is mixed with its own weight of caustic soda and fused. The cooled mass is pulverized, treated with dilute sulphuric acid and well boiled with steam. Filter to separate the silica. The filtrate is treated with ammonia, the precipitate is re-dissolved with sulphuric acid, and potassium sulphate is added to the solution. Evaporate down to the crystallizing point, and after most of the alum has crystallized out treat the solution with its own volume of alcohol, which precipitates the remainder of the alum, leaving only glucina and iron in solution. After distilling off the alcohol the iron and glucina are separated as in the first method.

METHOD OF PARSONS AND BARNES¹⁰

The powdered mineral (beryl) is mixed with its own weight of potassium hydroxide and fused in a carbondum crucible. The fused mass is broken up, just covered with water, and concentrated sulphuric acid is added in slight excess. The now gelatinous mass is heated and broken up until fumes of sulphuric acid are given off and the whole has the appearance of a fine white powder. The residue is next treated with hot water and on evaporation most of the aluminum crystallizes out as alum. Filter to separate the silica and the formed alum. To the filtrate which contains all the glucinum together with impurities add nitric acid and boil to oxidize the iron. Neutralize with ammonia and add enough sodium carbonate crystals to saturate the solution. Warm for 24 hr. with frequent stirring, when most of the glucinum will be left in solution almost perfectly free from aluminum and from nearly all the

iron. Filter. The residue is re-dissolved and re-treated as above, and all the glucinum will be found in the bicarbonate solution. Treat with ammonium sulphide to remove any dissolved iron. Filter, dilute the filtrate to 5 times its original volume and blow steam through the solution to the boiling point, when the glucinum precipitates as a fine granular basic carbonate which is easily filtered and washed. The basic carbonate thus obtained is pure save for about 2 per cent of occluded sodium salt. To remove this salt the precipitate is dissolved in hydrochloric acid, boiled to remove carbon dioxide, and treated with ammonia. Allow to settle, filter and wash with ammonium acetate solution to prevent the formation of colloidal hydroxide. The residue consists of glucinum hydroxide, which on drying and calcining yields glucina.

METHOD OF JAMES AND PERLEY¹¹

The mineral (gadolinite), crushed and pulverized, is treated in iron tanks with sulphuric acid, and heated until dense fumes of sulphuric acid are copiously evolved. The sulphated mineral is transferred into copper tanks, where it is stirred in a water solution. By adding the material slowly the temperature is not allowed to rise. The solution of sulphates is allowed to settle, the clear liquid is siphoned off and precipitated with a hot solution of oxalic acid. Allow to stand for 12 hr. Filter off the crystalline rare-earth oxalates and wash with boiling water. The glucinum and iron are in the filtrate, which is heated and treated with an oxidizing agent (say potassium bromate) in order to remove the excess of oxalic acid. Add ammonium hydrate followed by a concentrated solution of sodium hydroxide until the odor of ammonia is detected. Boil. The glucinum and iron are precipitated. Filter. The precipitate is treated with enough hydrochloric acid or sulphuric acid to dissolve about two-thirds of the whole, with constant stirring. This brings about the solution of all the glucinum and some iron. Filter. The residue is tested for glucinum, and if this is found, repeat the operation. The acid extract is heated to boiling and carefully precipitated with sodium hydroxide until a small amount of the filtered liquid gives a light colored precipitate with ammonium hydroxide, showing that nearly all the iron has been removed. Heat the filtrate to boiling, treat with an oxidizing agent to oxidize the iron, and precipitate with sodium hydroxide until a small amount of the liquid gives a white precipitate of hydroxide when treated with ammonia. Filter. The filtrate is treated with sodium-hydrogen sulphide to remove the last traces of iron. Filter. The glucinum is now precipitated as a basic carbonate by adding a concentrated solution of sodium carbonate to the boiling liquid. Filter. The precipitate is washed with boiling water, dried and calcined, yielding glucina.

METHOD OF COPAUX¹²

This method is based on the fact that sodium fluosilicate is decomposed at about 750 deg. C. into sodium fluoride, which fuses at about 980 deg. C., and silicon fluoride, a very active gas which at about 850 deg. C. decomposes the mineral beryl with the formation of sodium fluogluconate and sodium fluo-aluminate, the fluogluconate being very soluble in water and the fluo-

aluminate (artificial cryolite) nearly insoluble. The mineral is powdered and mixed with twice its weight of sodium fluosilicate, and the mixture is heated to 850 deg. C. The cooled mass is easily pulverized and treated with boiling water. All the fluogluccinate and only a small quantity of the fluo-aluminate are dissolved. Filter. The filtrate is treated with ammonia to transform the fluorine salts into hydroxides. Filter. The precipitate is dissolved in sulphuric acid, and the solution concentrated by boiling until white fumes of sulphuric acid appear, when it is certain that all the hydrofluoric acid has been driven off.

It is now best to treat the sulphates by any one of the methods mentioned above for the purification of the glucinum salt in a solution of sulphates.

Chemical and Electrochemical Separation of Glucinum

METHOD OF WÖHLER

As mentioned before Wöhler was the first to separate glucinum metal by reducing glucinum chloride with potassium. He has studied the product obtained and has assigned to it properties which have not been corroborated by subsequent studies on glucinum. This was due to the fact that his product was very impure.

METHOD OF DEBRAY²⁰

Debray in 1855 separated glucinum metal by reducing glucinum chloride with sodium in a current of hydrogen. The glucina is transformed into glucinum chloride by mixing it with charcoal and oil to the consistency of a paste and by heating this paste in a retort in a current of chlorine gas, when the glucinum chloride sublimes. The chloride and the sodium are placed in two separate parts of a retort cleaned of air by a current of hydrogen. Heat until the sodium fuses and the chloride vaporizes. The current of hydrogen carries the vapors to the fused sodium, when the chloride is decomposed with the formation of a dark mass consisting of sodium chloride and metallic glucinum. The mass is cooled and treated with water, which dissolves out the sodium chloride, leaving a residue of metallic glucinum of about 85 per cent purity.

METHOD OF NILSON AND PETERSSON²¹

Nilson and Petersson obtained the metal by heating to bright redness a mixture of glucinum chloride with a slight excess of sodium in a hermetically closed crucible of wrought iron. The separated glucinum was partly fused into globules and partly in the form of aggregations of little prismatic crystals, which in brightness and color resembled needles of polished steel. The average analysis of these two products gave 86.94 per cent glucinum, whereas the analysis of the globules gave 94.41 per cent metallic glucinum.

METHOD OF KRÜSS AND MORAHT²²

Krüss and Morahat separated the glucinum by reducing potassium-glucinum fluoride with sodium. The glucina is transformed into the double fluoride by dissolving it in hydrofluoric acid, adding potassium fluoride to the concentrated solution and crystallizing out the salt repeatedly. The crystals were heated to bright redness for 30 min. with a calculated quantity of sodium in a

steel crucible. The residue left, after washing with water, consisted of hexagonal crystals of glucinum and glucinum powder slightly contaminated with iron and glucinum oxide.

METHOD OF WARREN²³

Warren has separated glucinum by electrolyzing glucinum bromide. The basic glucinum carbonate previously obtained (see page 356) is intimately mixed with an excess of lampblack and ignited out of contact with the atmosphere. The mass thus obtained is converted into glucinum bromide by the action of bromine vapors at a full red heat in a clay retort. The sublimed bromide is dissolved and reduced to metallic glucinum by an electric current of 8 amp. and 12 volts.²⁴

METHOD OF BORCHERS²⁵

Borchers separated glucinum metal by electrolyzing potassium-ammonium-glucinum chloride. Basic glucinum carbonate, obtained by any of the methods given above, is transformed into glucinum chloride by dissolving it in hydrochloric acid with the addition of potassium chloride and the solution evaporated to dryness, giving glucinum-potassium chloride. This is mixed with ammonium chloride, and placed in an iron crucible, which also forms the cathode. The anode consists of a carbon rod. Fuse the mixture, and the glucinum is reduced by a current of 1000 amp. per sq.m. of electrode at 5 volts. It is necessary to avoid too high a temperature, otherwise a glucinum-iron alloy is formed instead of the glucinum metal.

METHOD OF LEBEAU²⁶

Lebeau obtained glucinum metal by electrolyzing sodium-glucinum fluoride. He prepared the double fluoride by dissolving in hydrofluoric acid exactly calculated proportions of glucinum hydrate and sodium carbonate and evaporating to dryness. The electrolysis is carried out very conveniently in a nickel crucible, which also serves as the negative pole, the positive pole consisting of a graphite rod which will not disintegrate under the influence of the current. First melt the salt by means of a bunsen burner, then pass the current and withdraw the heat. The mass remains in fusion. Avoid a heat exceeding a very dull red, otherwise alloys of glucinum-nickel will be formed. Use a current of 6 to 7 amp. and from 35 to 40 volts. The product obtained is a non-adherent, crystalline mass, which is isolated and treated with boiling water. After prolonged washing the disintegration is complete and the residue is a powder formed entirely of rather irregular crystals of glucinum of 99.81 per cent purity.

METHOD OF POLLOK²⁷

Pollok separates glucinum by reducing glucinum chloride with sodium. He obtained the chloride by mixing glucinum oxide with four times its own weight of sugar and heating the mixture to a dull red. The mixture of carbon and glucinum thus obtained is heated in a porcelain tube maintained at a bright red heat, and a steady stream of perfectly dry chlorine gas is passed over the heated mass. The chloride condenses in white silky needles beyond the red-hot zone of the

tube. This chloride is reduced by sodium in a nickel crucible. Sodium is placed at the bottom, then the chloride and then another layer of sodium. Cover well and heat until the reaction is complete. The whole mass is then plunged in absolute alcohol to dissolve the excess of sodium; boil with fresh portions of absolute alcohol, and finally wash with hot water. The glucinum thus obtained is a powder which after burnishing presents a white metallic luster.

METHOD OF FICHTER AND JABLOCYNSKI*

Fichter and Jabloczynski have separated the metal electrolytically by the method of Lebeau; but instead of using the salt composed of 1 molecule of glucinum fluoride and 2 molecules of sodium fluoride they reversed the proportions. They claim for this modification that the separation of the metal by dissolving the difficultly soluble sodium fluoride is made much easier. They obtained the double fluoride by mixing calculated quantities of glucinum carbonate or hydroxide with sodium carbonate and treating the mixture with hydrofluoric acid. The product is dried, fused and powdered. The powder is placed in a nickel crucible which also forms the cathode, the anode being a carbon rod. The current used is 7 to 10 amp. at 15 volts. The melt after electrolysis of 2½ hr. is removed from the crucible while still hot. After cooling and finely pulverizing, the substance is thrown, a little at a time, into a large volume of water with constant stirring. The salt dissolves almost immediately, the metallic residue being left on the bottom. The deleterious effect of the hydrofluoric acid which forms during the electrolysis is counteracted by the addition from time to time of a little ammonia and by frequent renewal of the water. The residue after washing with alcohol and drying gave on analysis 92.4 per cent glucinum metal. Microscopic examination revealed particles of glucinum oxide, which were separated mechanically by centrifuging the crude metal in ethylene bromide diluted with alcohol to a specific gravity of 1.95. The oxide settled at the bottom, leaving a 98 per cent pure metal suspended in the liquid. They also advise to avoid too high a heat, as they obtained during their work alloys containing 71.39 nickel and 27.61 glucinum, and one containing 72.07 nickel and 26.93 glucinum.

Brinton[†] followed the method of Fichter and Jabloczynski, but he found rather quantitative than qualitative differences in the results.

Properties of Glucinum

Glucinum is a white malleable metal, and can be easily forged and cold rolled into sheets. It takes a high polish and scratches glass, the hardness being between 6 and 7. Specific gravity 1.61[‡]; atomic weight 9.1. Its melting point is not yet known definitely. Its specific heat is the highest of any useful metal. According to Humpidge[§] the specific heat varies with the temperature up to between 400 deg. and 500 deg. C., when it becomes nearly constant, about 0.62. (See Fig. 1.) Its latent heat of fusion is abnormally high, possibly 300 calories. Its latent heat of vaporization is probably

higher than that of any known element, except carbon and boron. Its electrical conductivity is as high as that of silver, and thereby higher than that of copper. So far practically nothing is known about its tensile strength or rigidity, or about how it might be strengthened by small additions of other metals. Mendeleef places glucinum in the same group with magnesium, calcium, strontium and barium, and gives the following correlative proportions:

Glucinum does not exhibit allotropy. It is not altered in the air, nor does it burn even when heated to redness in a current of pure oxygen, but becomes covered with a thin coat of oxide which seems to protect it from further oxidation. It is not acted upon by cold or boiling water, nor by steam even at red heat.

FIG. 1. CURVE SHOWING SPECIFIC HEAT OF GLUCINUM AT VARYING TEMPERATURES

When heated by an electric arc in an atmosphere of hydrogen it volatilizes without fusion and condenses to a gray metallic mirror, like arsenic. It is not attacked by sulphur even when treated with sulphur vapors. Chlorine, fluorine and bromine attack it with incandescence and form the corresponding glucinum haloids. Iodine acts more difficultly. At the heat of an electric furnace it unites readily with silicon, forming a hard brittle substance susceptible of a high polish; it also unites directly with carbon and boron, and forms many alloys with a number of metals. It is attacked with evolution of heat by hydrochloric acid gas at a temperature produced by a small alcohol lamp and with evolution of hydrogen by dilute and concentrated hydrochloric acid. It is also attacked by concentrated sulphuric acid with evolution of sulphur dioxide, and by dilute sulphuric acid with evolution of hydrogen. It is not acted upon by dilute or concentrated nitric acid at ordinary temperature and only very slowly at a boiling heat.

It is not attacked by ammonia, but dissolves readily in a potash solution. Its salts are colorless when the acids are colorless, and a large majority of them are soluble in water. The solutions have a sweet taste and give an acid reaction. In dilute acid solutions glucinum is electro-negative to magnesium and electro-positive to aluminum.

To quote again Dr. J. W. Richards: "Beryllium (glucinum) is a metal which will well repay extended metallurgical research and minute physical and chemical study of its many unique properties."

Application of the Cottrell Process to the Recovery of Fume From Silver Refining Operations

Description of the Recently Installed Fume Precipitator at the United States Metals Refining Co.
Works—Construction of Header Chambers, Electrode Tubes and
Electrode System—Operation Control

By W. G. SMITH* AND A. A. HEIMROD†

THE application of the Cottrell electrical precipitation processes found early recognition as a standard means of removing the suspended particles of fume from exit gases arising from copper and lead smelting operations, as well as in the recovery of the fume from the further operation of refining the gold and silver by-products of these two major metals into commercial or marketable form.

It is the intent of this article, first, to touch briefly upon one of the earliest commercial Cottrell installations, placed in operation in one of the Eastern refineries, and, second, to describe in detail the latest developments in fume treatment by the Cottrell processes on virtually the same kind of fume. It is assumed that the readers of this article are familiar with the general principles of electrical precipitation, therefore these are not touched upon. Those, however, who wish to familiarize themselves on the terminology involved can do so by referring to the literature on the subject¹ in which will be found a very comprehensive discussion of its theory.

FIRST INSTALLATION AT THE RARITAN COPPER WORKS

The first commercial installation of this kind was the Cottrell plant installed at the Raritan Copper Works, Perth Amboy, N. J., where, in September, 1913, a box type precipitator was put into operation for the recovery of values in the fumes coming from furnace operations for the refining of copper slimes. This precipitator was of the horizontal gas flow type and was built in one section, having an active length of approximately 13 ft. and an active width of 8 ft. There were thirteen sets of discharge electrodes, making thirteen aisles or passageways in parallel through which the fume and gases passed and were subjected to the high voltage discharge from the discharge electrodes. These discharge electrodes consisted of 1-in. lead strips sharpened at the edges and spaced at equal intervals on the discharge electrode supporting frame. The gases, before they entered the precipitator, were passed through a scrubber and spraying system, where some of the fume in the gases was removed and the gas temperature lowered to approximately 150 deg. F. The spraying, in addition, performed the very vital function of humidifying the gases properly for later treatment

in the precipitator and ultimately the scrubbers were eliminated. The operating voltage was 40,000 volts, with a total power consumption of 3 to 4 kw. The box type treater on this problem caused considerable trouble due to building up of the fume on the collecting and discharge electrodes, and this, together with the nature and the composition of the fume, necessitated continual attention by the operator in order to keep the precipitator in service at a high point of efficiency. This precipitator was, however, operated continually until the summer of 1916, when a pipe type installation was placed in service.

INSTALLATION AT THE U. S. METALS REFINING PLANT

Since the installing of the initial electrical precipitation installation at the Raritan Copper Works, the art of precipitation of silver refinery fume has been advanced to a marked degree. The latest development along this line is the installation which has very recently been completed and placed into successful commercial operation at the plant of the United States Metals Refining Co. at Chrome, N. J.

The electrical precipitation installation on the silver refinery gases at this plant is installed at the end of a considerable length of flue system in which is also located a large settling chamber, spraying and scrubbing apparatus. The precipitator proper consists of a steel frame supporting lead top and bottom headers, connected by means of lead precipitator pipes. Three units are provided, each of which is suitable for handling approximately 4000 cu.ft. of gas per min. at 115 to 150 deg. F. at a velocity of 7 ft. per sec. through the pipes, or in case of necessity 8000 cu.ft. per min. at a velocity of 14 ft. per sec. through the pipes with only a very slight decrease in efficiency.

Each precipitator unit is 8 ft. 8 in. x 8 ft. measured from the inside of the precipitator column supports and has an overall height from foundation to the peak of the open top header of 34 feet.

PRECIPITATOR LEAD LINED

All of the parts of the precipitator which come directly in contact with the gases are made entirely of the very best high grade U. S. Smelting, Refining & Mining Co. electrolytic lead, free from impurities of antimony. It has been found that the gases containing selenium and selenic acid destroy lead which contains as low as 0.1 per cent antimony, therefore no lead containing antimony was used in the construction. Any steel work that might be subjected to exposure to the gases was covered with lead in such a way that no fume could come in direct contact with the iron.

The fumes and gases from the furnaces used in the silver refinery operations are conducted into the bot-

tom header through an inlet at each side of each unit close to the top of the bottom header chamber. Each of these inlets is provided with a liquid seal gas-tight jug damper in order to permit the shutting off of any unit and clear it entirely of gas without interfering with the operation of the remaining units, thereby giving to the whole installation flexibility and assuring continuous operation. These jug dampers are located on and supported by the top of the 2 ft. x 3 ft. rectangular bustle pipe extending along each side of the precipitator units. This bustle pipe is in turn supported by hanger rods from the main structure. (See Fig. 1.)

FIG. 1. CROSS-SECTIONS AND PLAN OF COTTRELL INSTALLATION, U. S. METALS REFINING CO.

The bottom header chamber is made of 8-lb. lead, the end walls being supported by lead clips fastened to the structural steel frame. In the bottom of the header box a 6-in. diameter lead drain pipe is provided in order to facilitate the flushing out of the collected precipitated material into settling tanks located alongside the precipitator. Ready accessibility to the bottom header is provided by means of doors which can be easily opened to inspect the electrode systems.

COLLECTING ELECTRODE PIPES

Each precipitator unit has 30 collecting electrode pipes 16 ft. long. Twenty-six of these pipes have an internal diameter of 8-in. and the four corner pipes have an internal diameter of 11 in. The increased diameter of these corner pipes permits installing of a stiff electrode to steady the discharge electrode system and prevent it from swinging or swaying due to irregularities of gas flow or in electrical conditions. This avoids the use of insulators in the bottom header and thereby eliminates possibilities of insulator leakage trouble at this point. (See Fig. 1.)

The precipitator pipes extend into the bottom header 4 ft. The gas inlets are so arranged that the gas flows in near the top of the bottom header box, circulates around the pipes, flows down to the bottom, then up through the pipes and discharges into the top header box. This arrangement tends to break up any irregularities in the flow of the incoming gases, equalizes the gas pressure in the bottom header, tends to heat all of the pipes to a uniform temperature and thus insures proper distribution of the gas in the various pipes. The gases passing through the electrical field are cleaned and are discharged at the top of the precipitator into the top header and to atmosphere. The solid and liquid particles carried by the gas are collected on the inside surfaces of the collecting electrode pipes, from which the precipitate is periodically washed into the bottom header by means of a washing system installed in the top header. This cleaning operation is performed only on idle units, the gas temporarily being diverted to other units and the electric power line switch opened. This can readily be done, as high voltage selector switches have been installed in the electrical house whereby a precipitator unit can be put in or taken out of service without disturbing the operation of the electrical equipment or gas flow to the remaining units.

The top header of each precipitator unit is lead lined throughout and open to atmosphere at the top. The end walls of these headers have been provided with two openings to allow the high tension framework to pass through to the steel insulator compartments, where it is supported on 3-ft.-high corrugated pillar type insulators. These are properly hooded with steel hoods in order to protect the insulators from moist gas and bad weather conditions.

The installing of the collecting electrode pipes was accomplished by passing a mandrel through the pipes so as to remove any irregularities such as projections or dents. They were then passed through the lead-covered steel top header supporting plate, which was drilled to allow the pipes to pass through freely to the second steel lead-covered supporting plate 9 ft. 9 in. below the top header. After the pipes were in place they were burned to the sheet lead covering on the supporting plates and to the top plate of the lower header, thereby making the pipes hang plumb and assuring a tight joint around pipes where they enter the bottom header.

THE ELECTRODE SYSTEM

The discharge electrode system of each unit consists of, first, four corrugated pillar type insulators¹, two on each side of the precipitator unit, insulating the high tension frame from ground, these insulators, as stated before, being protected against bad atmospheric conditions by means of sheet iron hoods. Second, the electrodes are made up of a star section lead-covered iron wire, carefully centered in the pipes and supported from 2-in. pipe bus bars. The corner pipes have stiff electrodes made of 1½-in. lead-covered extra heavy wrought iron pipe. Around that portion of the electrode that is in the precipitator pipe is a spiral of star section lead-covered iron wire² the same as used in the other pipes. Third, the electrode system is tied together at the bottom by a sway frame to the stiff corner electrodes, and on the end of each electrode in order to hold it straight in the center of the pipe is a 20-lb. lead weight.

¹Research Catalog No. 3-1-3.

²Research Catalog No. 3-E-1

ELECTRICAL EQUIPMENT

The electrical equipment for the transformation of the available power supply at 250 volts direct current to the required potential of 65,000 volts is placed in a building close to the base of the precipitator.

The supply lines run through a main line switch and fuses mounted in a steel cabinet on the wall and from this point to the switchboard. This arrangement makes it possible to disconnect entirely the main switchboard buses and all auxiliary wiring from the power supply lines.

The switchboard consists of two slate panels, each having a main and a lower section, and each controlling independently one of the duplicate sets of electrical apparatus. The lower panel sections are reserved for the motor starter face plate, manual operating handle, overload and under voltage trip coils. The main sections of each panel have mounted upon them all the control equipment except the motor starters and high tension switching devices. On each main section is a single pole circuit breaker in the motor circuit (protecting that side of the circuit not protected by the overload coil on the motor starter); a main line motor switch; a generator field switch and a field discharge resistance; a generator field rheostat operating handle (with rheostat on the back of the panel); a double pole, overload trip, under-voltage release, circuit breaker in the line from the generator to the transformer; a rheostat switch; a double pole double throw reversing switch and a transformer tap switch in this same line; and a voltmeter and an ammeter in the transformer circuit. By means of a potential plug the voltage may be measured either at the generator terminals or the transformer terminals, the difference being the voltage drop across the line rheostat (plus a small line drop).

GENERATOR EQUIPMENT

The two motor generator sets consist of a 40-hp., 220-volt, 150-amp. motor and a 25-k.v.a., 220-volt, 113-amp. single-phase 60-cycle generator, both manufactured by the Westinghouse Electric & Manufacturing Co., and supplied to generate the alternating current. The mechanical rectifiers, directly connected to and therefore operated in synchronism with the motor generator set, were manufactured and supplied by the Research Corporation. Near the rectifiers are the high voltage transformers rated as follows: 25 k.v.a., 200 volts low tension, 75,000 / 70,000 / 65,000 / 60,000 /

FIG. 3. INSTALLATION IN OPERATION WITH 8000 CU.FT. OF GAS, CURRENT OFF

55,000 volts high tension; 60 cycles, complete with oil gage and choke coils. The arrangement of the apparatus is such that the high-tension equipment of each set is completely screened off from the other set and from the low-tension apparatus.

The "path" of the electric power is from the generator at 220 volts, single phase, 60 cycles, through the switchboard control equipment and line rheostat to the transformer at the same frequency but at reduced voltage (line rheostat drop). The transformer "steps up" the voltage to about 65,000 volts and furnishes power at this voltage directly to the mechanical rectifier without going through any switching devices. Choke coils in the transformer circuit and resistances in the line afford protection against surges. The rectifier reverses the polarity of one-half of each complete cycle and supplies unidirectional current at about 65,000 volts to its main high-tension bus. One terminal of the rectifier is permanently grounded. Each rectifier is connected directly without switching devices to its individual high-tension bus. The three lines from the precipitator units are brought in through the wall of the building near the roof to three separate switching buses, which are so arranged that by means of a grounded mechanical remote control handle near the motor generator sets any or all of the three precipitator units may be connected to either of the main power buses. These switches can be operated with the buses alive, and the change over from one unit to another can be made in a very short time. It is good practice to reduce the voltage about 25 per cent before undertaking any high-tension switching. The high-tension switches are provided with padlocks so that a mechanic before going to work on a precipitator unit can lock the switch in an open position, take the key with him and be certain that voltage cannot be applied to the unit upon which he is working, the operator meanwhile being free to manipulate the two other precipitator units without interference.

THE PRECIPITATOR AND ITS OPERATION

A fair idea of the precipitator may be obtained by examining Figs. 2 and 3, which show the end view of one unit; top header, insulator compartment, pipes, part of the bottom header, jug damper and main flue system. Part of the electrical equipment building with monitor, to hold the inlet bushings, can be readily located alongside the flue system.

FIG. 2. INSTALLATION IN OPERATION WITH 8000 CU.FT. OF GAS, CURRENT ON

Fig. 2 shows the precipitator operating at full capacity under normal operating voltage and Fig. 3 with the high-tension current shut off. The fume being very light in color, it is difficult to obtain a clear idea from the photograph of the contrast between "current on" and "current off" conditions, but careful note of the lamps on the top platform in each illustration will serve to emphasize this difference.

The precipitator operates as close to 100 per cent clearance as any one can wish for, and this condition is always maintained on account of the high values in the fume recovered. As soon as this precipitator becomes overloaded with the precipitated fume in the precipitator pipes the operator can readily detect this condition by his instruments on the switchboard and by the general operation and appearance of the spark at the rectifier. The high-tension selector switches in the electrical equipment house are then operated, to cut in the spare unit; the jug dampers on the inlets to the units are opened or closed as the case may be to put the unit into service or to take it out. The precipitate is then washed from the pipes by means of the flushing system. This operation varies, due largely to the selenium content of the fume; the higher the percentage of selenium in the precipitated fume the more often it is necessary to take a unit out of operation to clean the collecting and discharge electrodes.

The recoveries, judging from the short time the precipitator has been in operation, will be even greater than those indicated by the preliminary single pipe tests based on which appropriations for the construction of the commercial installation were readily made.

Exportation of Refined Sugar From U. S.

The suspension of the exportation of refined sugar from the United States by order of the United States Sugar Equalization Board, in order to correct local deficiencies and prevent the upward movement of local prices, lends interest to a statement compiled by the National City Bank of New York showing the exportation of refined sugar from the United States during the last fifty years. It shows that the quantity of refined sugar exported in the 5 years since the beginning of the war is more than double that of the half century preceding the war. The quantity sent out of the country in the 5 years ended with June, 1919, is in round terms, 5,000,000,000 lb., against 2,000,000,000 lb. in the half century preceding the war, and the value in the 5-yr. war period was \$290,000,000, against \$120,000,000 in the half century prior to the war.

The sudden demands on the United States for refined sugar which came with the beginning of the war, says the bank's statement, is due to the fact that most of the European countries which had formerly relied for their sugar upon the beet fields of Germany, Austria-Hungary and Russia found their usual supplies cut off by the war and were compelled to look to the cane sugar area of the world for supplies. The cane sugar area is chiefly Cuba, Porto Rico, Hawaii, the Philippine Islands, Java and India. Cuba and our own islands send their raw sugar to the United States to be refined; India consumes all of its sugar locally; and Java exports a large proportion of her product in the raw state to her neighbors in the Orient, especially India, Australia and Japan. The Latin-American countries, which produce about 1,000,000 tons annually, have little for exportation. This left Cuba and the islands belonging

to the United States as the chief available source for cane sugar, and as all of these islands have been sending their raw products to the United States for refining, quite naturally the European countries requiring sugar turned to this country for supplies of the refined article.

As a consequence of this condition the quantity of refined sugar exported from the United States in our fiscal year 1915, the first year of the war, was 550,000,000 lb., in 1916 1,630,000,000, in 1917 1,250,000,000, in 1918 575,000,000 and in 1919 about 1,000,000,000 lb.

While export prices prior to the war were much higher than those in the period immediately preceding the war, they were materially less than those in the early part of the 50-yr. period prior to the war. The average export price of the refined sugar sent out of the United States during the war ranged from 4.7c per lb. in 1915 to about 7.1c in 1919, while the average export price in 1871 was 13.2c per lb., in 1875 10.8c, in 1880 9.0c, 1890 7.0c, 1900 4.5c, 1905 3.5c, and in the fiscal year 1914, all of which preceded the war, 3.6c.

While most of the exportation from the United States has gone to Europe, the other parts of the world are gradually turning to the United States as a new source of supply, and the exports of refined sugar in the fiscal year 1918 were: to Argentina 93,000,000 lb., Uruguay 21,000,000, Mexico 18,000,000, Canada 12,000,000, Africa 4,500,000, and to Asia (chiefly Japan and India) nearly 1,000,000 lb.

This habit of the cane sugar producers of America of sending their product to the United States to be refined grew out of the fact that the United States was the chief consumer of their product, while Europe, the other great sugar-consuming section of the world, was supplied from the beet fields, especially those of Germany, Russia, and Austria-Hungary. The United States consumed at the beginning of the present century one-fourth of the sugar of the world, but with the great enlargement of world production which followed the year 1900 the share of the world's crop consumed by us fell to about one-fifth, although the quantity consumed by us steadily increased. World production in 1900 was 19,000,000 lb., in 1910 33,000,000,000 and in 1914 42,000,000,000, and as a consequence of this tremendous increase in production, the percentage of the world's crop consumed by us fell from 25.7 per cent in 1910 to 20.9 per cent in 1914, although our consumption grew from 4,477,000,000 lb. in 1900 to 8,793,000,000 in 1914.—*Fortnightly Information Review*, Aug. 1, 1919.

Foreign Trade of France for Six Months

Imports into France for the first 6 months of 1919 were valued as follows: Food products, 3,488,837,000 francs; industrial material, 5,000,621,000 francs; manufactured articles, 3,638,745,000 francs; total, 12,128,203,000 francs.

Exports were: Food products, 249,272,000 francs; industrial materials, 382,190,000 francs; manufactured articles, 1,464,875,000 francs; postal packages, 162,147,000 francs; total, 2,258,484,000 francs.

Imports from the United States were valued at 3,774,858,000 francs; from England, 3,243,306,000 francs; and from Argentina, the next important country, 567,389,000 francs.

Exports to the United States totaled 160,492,000 francs; to England, 533,176,000 francs; and to Belgium, the next important country, 262,152,000 francs.

Notes on the Metallurgy of Wulfenite*

Source and Importance of Wulfenite—Description of Its Metallurgical Treatment, Acid Leach, Alkaline Leach, and Fusion Methods—Comparison of These Methods—Costs of Treatment—Tabulated Results

By J. P. BONARDI

Assistant Chemist, U. S. Bureau of Mines

VERY little information concerning the hydro-metallurgical treatment of wulfenite ores has appeared in the technical journals. Those who have developed processes for the treatment of such ores are either working the methods behind closed doors or have patented their ideas and, as a consequence, little is generally known about the subject.

The molybdenum market at the present time is being supplied principally from the ore molybdenite, MoS_2 . This has been chiefly due to the fact that there are larger deposits of this mineral than wulfenite in the United States. The advent of flotation and its adaptability to the concentration of molybdenite resulted in the United States producing, during the war, more molybdenum than any other country in the world; and it would be safe to say that nearly 90 per cent of this came from molybdenite ores. The principal working deposits of this ore are located in Colorado, at Climax and at Empire. Other deposits being worked at the present time are at Questa, New Mexico, and near Nogales, Arizona. Colorado, Arizona, New Mexico, California, Montana and Washington constitute the principal States where either molybdenite or wulfenite, or both, occur. These, as well as the minor deposits of molybdenum ores in the United States, are described by F. W. Horton.¹

SOURCE AND IMPORTANCE OF WULFENITE

Until recently wulfenite ores constituted the principal source of molybdenum in this country. Horton¹ states that:

"Wulfenite ores from Arizona have supplied the larger part of the molybdenum produced in this country to 1915, and on account of the ease with which they are concentrated they should prove a strong competitor of molybdenite for markets that do not require concentrates with a high molybdenum content."

Besides the deposits occurring in Arizona, wulfenite has been reported in several scattered localities throughout the Western States of Nevada, New Mexico, Utah, California and Montana. Several of these deposits of wulfenite might be worked at a profit and would have a better chance to compete with molybdenite if sufficient information could be obtained concerning a profitable metallurgical treatment for the concentrates.

The successful concentration of wulfenite ores presents few difficulties, as the ordinary wet processes of concentration by jigs, tables and vanners, such as are used in the concentrating mills for treating lead, copper, zinc and pyrite ores, may be applied with success on wulfenite ores, which are also amenable to pneumatic separators of various types. Vanadinite and

several of the lead minerals—cerussite, anglesite, galena, pyromorphite and mimetite—which oftentimes occur with wulfenite are also recovered in the wulfenite concentrates, being of practically the same specific gravity. Usually a concentrate of 15 to 20 per cent MoO_3 is the best obtainable when the above-mentioned lead minerals occur to any extent in the ore. A pure wulfenite mineral contains 39.23 per cent MoO_3 and 60.77 per cent PbO . Wulfenite buyers sometimes specify that the ore should contain a minimum of 20 per cent MoO_3 , or 13.33 per cent Mo. Though the presence of other lead minerals would lower the grade of concentrates, any smelting process employed would recover the lead, which would also carry along the precious metals, gold and silver, which sometimes are found associated with the wulfenite crystals or in the lead gangue minerals. Horton¹ cites a case where gold was found as native metal in the wulfenite crystals themselves. The Mammoth mine, about 3 miles from Mammoth, at Shultz, Pinal County, Arizona, was worked originally for its free gold content. Part of the tailings from these workings later supplied 750 tons of wulfenite concentrates out of 795 tons of combined wulfenite and molybdenite concentrates that constituted the total production of this country in 1903.²

PURPOSE OF INVESTIGATION

In view of the little that has been published concerning the metallurgical treatment of wulfenite ores and the difficulties connected with some of the processes used, it was deemed advisable to make a preliminary study into the metallurgical possibilities of wulfenite. Although the now known commercial deposits of wulfenite may not be able to supply the molybdenum demand even in normal times, this mineral may still prove to be a strong competitor of molybdenite in the future. Wulfenite offers some advantage over molybdenite in that any successful process for recovering molybdenum would necessarily recover the lead and any precious metals as by-products, and thus reduce the cost of treatment.

The material used consisted of wulfenite concentrates kindly furnished by the Rowley Copper Mines Co., Gila Bend, Arizona. Analysis of the concentrate gave the following results:

	Per Cent		Per Cent
MoO_3	23.77	Mo	15.85
PbO	47.93	Pb	44.53
Fe_2O_3	1.16		
Al_2O_3	1.34		
SiO_2	4.90		
V_2O_5	.74		
P_2O_5	.20	P	.08
As_2O_3	1.02	As	.66
BaSO_4	18.56		
Total determined	99.62

⁴Pratt, J. H., "The Steel-Hardening Metals: Mineral Resources, U. S., for 1903," U. S. Geol. Survey, 1904, p. 308.

An assay for gold and silver gave respectively 0.007 and 0.293 oz. per ton of material, quantities altogether too low to justify commercial recovery. The above content of MoO_3 indicates a product containing 60.59 per cent of lead molybdate. Although the sample could have been graded up by elimination of the barium sulphate and siliceous gangue matter, this was not deemed advisable, since the molybdenum content was representative of the usual run of wulfenite concentrates. The presence of vanadium, arsenic and phosphorus and the excess of lead oxide indicated the presence of vanadinite, mimetite, pyromorphite and other lead minerals. Aside from the contained molybdenum, the material would be considered a valuable ore to smelt for its lead content alone.

METALLURGICAL TREATMENT

Any metallurgical treatment for wulfenite ores should include the recovery of the lead and precious metals besides the molybdenum. The principal methods may be classed under three general heads:

- (1) An acid leach.
- (2) An alkaline leach.

(3) Fusing the ore with some material that will give the lead in metallic form carrying the gold and silver, and the molybdenum as a soluble compound in the slag which can be extracted by solution methods or may be used directly in the electric furnace for the preparation of ferromolybdenum.

(1) *Acid Leach Method.* Treating wulfenite material with any acid or combination of acids did not offer any special advantage. Wulfenite is only soluble in acids when used in considerable excess and concentration. The cost of alkali to neutralize such a solution, in order to obtain proper conditions to precipitate the molybdenum from solution, is prohibitive. Further, lead is found in solution, or in the residue, depending upon what acid is used, and requires further treatment. Experiments conducted in this laboratory upon vanadinite concentrates which respond with acids similarly to wulfenite indicated the necessity of large excess of acids to effect complete solution and therefore considerable quantities of alkali for neutralization prior to precipitation. If an ore contains any gold or silver values, the recovery of such values with such a treatment requires further expense. In addition, the elimination of arsenic, phosphorus or other elements from solution makes this method of treatment complicated and expensive. If molybdenum is to compete with vanadium, an expensive method of ore treatment cannot be used, even though the metal vanadium has a high price at present. In view of these facts, detailed experiments were not conducted with acids, as the smelting processes, described later, offered better possibilities for recovering the lead as bullion together with any gold or silver values.

(2) *Alkali Leach Method.* Strong solutions of caustic or alkali carbonates will render only a very small percentage of the wulfenite soluble, so these methods of treatment were discarded. The solubility of wulfenite in hot sodium sulphide solution was first noticed by the writer during the course of sulphidizing wulfenite material previous to flotation experiments. The solubility of wulfenite in sodium sulphide is fairly complete in boiling solution, and from this solution, after the elimination of impurities, such as phosphorus and arsenic, the molybdenum can be recovered as calcium

molybdate. The exact conditions necessary for precipitating molybdenum as calcium molybdate from alkali solutions will be described later in detail under fusion methods.

The sodium sulphide treatment offers an excellent method for treating wulfenite, as the lead, together with the precious metals, will be found in the residue as sulphides in a concentrated form, which can easily be shipped to the smelters for further treatment. The molybdenum goes into solution as sodium molybdate.

A method, somewhat similar, for treating vanadinite is described by G. Fester in German patent No. 294,932.⁴ A description of this method is as follows:

"A V-Pb ore is finely ground and boiled, with stirring, with a solution of Na_2S , whereby the following reaction takes place: $\text{Pb}_3(\text{VO}_4)_2 + 3\text{Na}_2\text{S} = 3\text{PbS} + 2\text{Na}_2\text{VO}_4$. The resulting solution, still containing an excess of Na_2S , is saturated with fresh ore according to the counter-flow process, whereby all sulphur is taken up by the lead ore with the production of a sodium vanadate solution entirely free of sulphide, from which ammonium vanadate can be separated by means of ammonium chloride. If vanadic acid or iron vanadate is to be obtained, Cl_2 is conducted into the hot sodium vanadate solution, until it is only weakly alkaline. By this treatment, at first small amounts of dissolved SiO_2 and Al_2O_3 are separated; secondly, the thiosulphate formed from the sulphide by oxidation is further oxidized to sulphate, and thirdly, arsenite is converted into arsenate and can be precipitated in the known manner as the ammonium magnesium double salt, together with any H_3PO_4 which may be present. From the purified solution V_2O_5 is obtained by acidifying, or iron vanadate is obtained by the addition of FeSO_4 ."

It is known that the method of treating wulfenite concentrates with sodium sulphide is now being used by at least one company in the United States. This company is now producing high-grade calcium molybdate of about 60 per cent MoO_3 content, practically free from sulphur, phosphorus and arsenic. The high-grade calcium molybdate thus produced can be used for the manufacture of ammonium molybdate, ferromolybdenum, or added directly to molten steel in the manufacture of special alloy steels.⁵ The molybdenum in the calcium molybdate is easily reduced to the metal by the carbon or silicon in the steel at the temperature of the molten bath. This method of utilizing calcium molybdate has the further advantage of introducing only small impurities into the steel, but allowance must be made for the carbon used in reducing the calcium molybdate.

(3) *Fusion Method.* Since it is desirable to collect the lead as bullion, which requires a reducing flux in the treatment of the ore, it would be useless to try any melt which would not give reducing conditions, even though the molybdenum could be leached from the fused mass. A calcium chloride flux would react to form calcium molybdate, which would be insoluble in water. Attempts to fuse wulfenite ore with the common fluxes, such as niter cake, sodium bisulphate, sodium nitrate, sodium sulphate, calcium chloride, sodium chloride, or a combination of these chemicals with carbon, were not made therefore except with salt

⁴Fester, G., "Extracting Vanadium Ores by Treatment with Alkali Sulphide," *Chem. Abstr.*, vol. 12, No. 8 (1918), p. 953.

⁵Kissack, Alan, "Process of Making Alloy Steel," U. S. Patent 1,300,279, April 15, 1919.

In the fusion conducted with salt it was found that molybdenum would volatilize as the chloride, the amount depending upon the duration of treatment and the temperature. Attempts to use excess of salt and carbon, besides volatilizing some molybdenum, gave no lead button. When four parts of molybdenite ore were treated with one part of sodium chloride in a clay scorifier at 1000 deg. C. as much as 98 per cent of the molybdenum was volatilized.

FUSION EXPERIMENTS WITH SODA ASH AND CARBON

One commercial fusion method involves the use of soda ash and carbon. The lead is recovered as bullion along with any gold or silver, while the molybdenum remains in the slag as sodium molybdate. The sodium molybdate slag, if sufficiently high in molybdenum content, is used in the electric furnace in the manufacture of ferromolybdenum. The ore, soda ash and carbon are charged into a lead blast-furnace of the ordinary type, or water-jacketed, and the charge smelted to recover the lead as bullion. The proportion of fluxing material varies with the class of ore treated, but in all cases a considerable excess is necessary to insure a high recovery of the molybdenum. A similar method was used at one time for smelting vanadinite ore at Cutter, New Mexico. The method is described by Grider.⁷

In the above method it is desirable that the slag shall carry as much molybdenum as possible, with a minimum amount of alkali, on account of the corrosive action of the alkali on the linings of the furnaces used for making ferro. On account of this difficulty, the method has been more or less discontinued.

In view of these facts, it was deemed advisable, first, to determine the minimum amount of fluxing material necessary to recover completely the lead as bullion and at the same time extract the molybdenum as sodium molybdate; and, second, to recover the molybdenum from the slag as a product which when used in an electric furnace would eliminate the trouble heretofore experienced with the furnace linings.

The possibility of precipitating a molybdate as calcium molybdate having less basic properties than sodium molybdate was suggested to the writer in the fall of 1917 by Dr. R. B. Moore, superintendent of the Colorado Station. Previous to this time, in 1915-1916, attempts had been made in the laboratory of the Colorado Station to precipitate a molybdate from an alkali leach using calcium chloride, barium chloride and ferrous sulphate, but in no case was the precipitation complete; and no further attempts were made until the early spring of 1918. During the past year, working at interrupted intervals, a series of fusion experiments have been conducted, and the exact conditions for precipitating molybdenum completely as calcium molybdate have been found.

The following data represent the results of the experiments which, though performed on a small scale, are applicable to commercial conditions. Since the exact conditions for precipitating calcium molybdate have been determined, they can be applied to any sodium molybdate slag produced either by the fusion process or by the alkali sulphide leach method. Many of the standard textbooks on chemistry have mentioned the compound calcium molybdate, but the details for complete precipitation from solution are lacking.

Several preliminary fusions were conducted using soda ash and carbon. The sample of wulfenite concentrate which has been described was crushed to pass 100 mesh, and all fusion experiments were conducted upon this material. By using a minimum charge of soda ash and carbon (0.75 soda ash, 1 ore; 0.05 carbon), the lead could be completely reduced to the metal, but in order that this should collect in a button the maintenance of a high temperature was required. This was probably too high for a lead blast-furnace, without seriously affecting the furnace lining. It was found that the molybdenum from such a fusion could be completely leached from the slag. Sodium carbonate alone has a melting-point of 849 deg. C. and, when mixed with ore in about equal proportions, a considerably higher temperature is required before the mass becomes liquid. Although soda ash can be used for smelting wulfenite to form soluble sodium molybdate, the use of salt and sodium hydroxide in combination with soda ash presents some advantages, since such a mixture requires a lower temperature to effect a fusion, and consequently gives less trouble with furnace linings. Salt, besides the above advantages, would, if successful in replacing soda ash, effect a saving in cost of chemicals. On the other hand, although caustic soda costs a little more than soda ash, the advantages gained in its lower melting-point and its efficiency in decomposing wulfenite would probably repay the additional charge over soda ash used alone.

FUSION EXPERIMENTS WITH SODA ASH, SALT AND CARBON

Table I gives in a brief form the results of the fusion experiments using soda ash, salt and carbon.

In the following runs and subsequent experiments, fusions were made in iron-spun crucibles in a small electric furnace and carried to the point where the mass became liquid. While hot, the fused mass was poured into a conical iron mold so that the lead button

TABLE I

No. of Run	Weight of Ore, Grams	Weight of Na_2CO_3 , G.	Weight of NaCl , G.	Weight of Charcoal, G.	Ratio Ore to Na_2CO_3	Ratio Ore to Flux	Extraction % as Sol. Sodium Molybdate	Recovery of Pb as Metal in a Button	Remarks
1	10	10	10	1	1:1	1:2.1	85.09	80.90	Metallic lead globules disseminated throughout mass.

could be collected and weighed separately. After cooling, the fused mass was broken up, dissolved and filtered, and the filtrate made up to a volume of one liter. An aliquot portion of 10 cc. was taken for analysis and for the alkalinity tests as described later. The molybdenum was determined after making this alkaline solution acid with sulphuric acid, then passing the solution through a Jones reductor and titrating with a one-twentieth normal permanganate.

13	20	20	10	1	1:1.55	93.90	97.8	Fluid.

A review of the results of the experiments as given in Table I shows that the use of sodium chloride with soda ash, although it lowered the temperature of fusion somewhat, did not indicate that it could be substituted for soda ash, as the per cent recovery of lead and molybdenum fell off in attempts to use a flux containing less than 75 per cent soda ash to ore. The lead globules do not run together so well into a button when the soda ash is decreased and the salt increased in the fluxing charge. In a run using straight salt and carbon there was no reduction of the lead to metallic form. Further, at the temperature which the fusion required, there was a loss of molybdenum, as the chloride, from the baked cake on the side of the crucible.

The use of soda ash and caustic in combination, as shown in Table II, Run 9, where the ratio of ore to combined fluxing material was 1:0.75, gave over 95 per cent recovery of lead and molybdenum. This run was the best from the standpoint of molybdenum extracted and lead recovered, with the minimum amount of fluxing material. Runs 7 and 8 gave good recoveries of lead, indicating that the lead minerals had been decomposed, but not enough excess alkali was left over from the reaction to combine with the molybdic oxide to make the most soluble salt of sodium molybdate. Molybdic oxide combines with the requisite quantity of sodium carbonate or caustic soda to form at least six different molybdates from the normal sodium molybdate ($\text{Na}_2\text{Mo}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$), the most soluble variety, to decamolybdate ($\text{Na}_2\text{Mo}_{10}\text{O}_{31} \cdot 12\text{H}_2\text{O}$), which is only slightly soluble. The least soluble is the sodium octomolybdate ($\text{Na}_2\text{Mo}_8\text{O}_{27} \cdot 4\text{H}_2\text{O}$); this compound under the proper conditions can be crystallized out of solution. As a salt of this character had no special advantage for recovering molybdenum from solution outside of its purity, no attempts were made to make use of this insoluble property of octomolybdate.

The use of a proportion of flux—less than 75 per cent of the weight of ore—could in all probability be employed on wulfenite which did not contain such a large percentage of barite as this material. As the analyses indicated, it contained 18.56 per cent BaSO_4 and besides requiring the presence of caustic soda as a flux, enough soda ash must be added to convert the sulphate to carbonate so that barium carbonate would be left behind with the residue and prevent barium hydroxide from

going through into the filtrate. In every run made, analyses of the leached liquors containing the sodium molybdate gave no test for vanadium, iron, barium or phosphorus; and these were found left behind with the insoluble residues. Practically all the silica remained in the residue.

PRECIPITATION OF MOLYBDENUM AS CALCIUM MOLYBDATE

As previously explained, the precipitation of molybdenum from an alkali leach solution as calcium molybdate offers the following advantages:

1. Under the proper conditions a complete precipitation can be made.
2. CaMoO_4 may be used in the manufacture of special alloy steels.
3. CaMoO_4 may be used in the electric furnace in manufacture of ferro-alloys.
4. CaMoO_4 may be used for the preparation of purified chemical salts.

The precipitation experiments on calcium molybdate were made on 100 cc. aliquot portions of solutions which were obtained from the previous fusion runs as indicated in Tables III and IV. The methods of preparing these solutions from the fusions have been previously described.

TABLE III

Precipitation With Large Excess of CaCl_2 Solution at Room Temperature					Remarks
Leached Solution From Run No.	Mo Extracted by Leach	Grams Mo per Liter of Solution	Per Cent Mo Precipitated as CaMoO_4		
1	85.09	1.35	47.30		Solution stood over night before filtering.
2	83.10	1.32	49.60		Solution stood over night before filtering.
3	89.30	1.41	50.90		Solution stood over night before filtering.
12	91.05	5.96	40.03		Solution stood over night before filtering.
13	93.90	2.88	60.00		Solution stood over night before filtering.

The above figures clearly indicate that molybdenum cannot be precipitated completely at room temperature by calcium chloride solution, even if employed in large excess and allowed to stand several hours. The best precipitation found was 60 per cent, that of run No. 13, given above. To be certain that an excess of calcium chloride had been used the filtrate from the calcium molybdate precipitation was tested for the presence of calcium salts.

TABLE IV

Precipitation by Slaked Lime Emulsion at Room Temperature					Remarks
Leached Solution From Run No.	Mo Extracted by Leach	Grams Mo per Liter of Solution	Per Cent Mo Precipitated as CaMoO_4		
5	97.4	6.18	8.9		Excess amount of slaked lime added to bottle—shaken 6 hr.
6	98.2	6.23	7.8		Excess amount of slaked lime added to bottle—shaken 6 hr.
11	99.1	6.28	8.4		Excess amount of slaked lime added to bottle—shaken 6 hr.

As indicated above, the use of slaked lime with prolonged agitation gave at the best less than 9 per cent precipitation of molybdenum.^a Attempts to use a

^aExperiments performed in this laboratory for precipitating vanadium in the presence of molybdenum were successful by using slaked lime in a boiling solution. The alkalinity of the liquor was found to be increased by this treatment—a fact which assists in keeping molybdenum in solution. No special alkalinity was necessary or desirable for the precipitation of the vanadium, as some of the liquors after precipitation of the vanadium varied in alkalinity from an equivalent of 27.4 to 73.1 g. of sodium hydroxide per liter. See Conley, J. C., "A Proposed Metallurgical Process for the Treatment of Vanadinite for the Recovery of Lead and Vanadium," *Chem. & Met. Eng.*, vol. 20, No. 10, p. 514.

large excess of CaOCl_2 , bleaching powder solution, at room temperature on duplicate solutions of runs 5, 6 and 11, gave respectively 73.1, 77.9 and 66.9 per cent molybdenum precipitated; indicating that the complete precipitation did not depend upon the oxidized state of the molybdenum in the leached liquors. Bromine was tried as an oxidizing agent, followed by excess calcium chloride at room temperature, without improving the results. However, on boiling these solutions the molybdenum was completely precipitated.

TABLE V

Precipitation From Run No.	With Excess CaCl_2 Mo Extracted by Leach	Conc. of Mo per Liter	Followed by Boiling the Solution Per Cent Precipitated as CaMoO_4	Remarks
5	97.4	6.18	99.8	Solution boiled until precipitate formed became granular.
6	98.2	6.23	98.6	Solution boiled until precipitate formed became granular.
11	99.1	6.28	97.2	Solution boiled until precipitate formed became granular.
4	92.7	5.88	98.6	Solution boiled until precipitate formed became granular.
9	96.7	6.12	98.3	Solution boiled until precipitate formed became granular.
10	97.8	6.20	95.6	Solution boiled until precipitate formed became granular.

The fact that in every one of the experiments described over 95 per cent of the molybdenum was precipitated by boiling the solution, after adding calcium chloride, clearly shows the importance of boiling, since the best precipitation, after prolonged standing at room temperature, as given in Table III was only 60 per cent. The necessary amount of calcium chloride needed for complete precipitation has been worked out and will be given in detail.

CONDITIONS FOR PRECIPITATION

The complete precipitation of molybdenum is brought about only in practically neutral solutions. That is, sufficient calcium chloride solution should be added to completely combine with all the carbonate and hydroxyl radicals in solution up to the limits of the solubilities of CaCO_3 and Ca(OH)_2 , which will be precipitated along

TABLE VI

Alkalinity Tests on Fusion Leached Liquors From 40 Grams Concentrates, and Total Alkali Equivalents

Leached Solution From Run No.	Grams Na_2CO_3	Equivalent Grams NaOH	Equivalent Grams CaO	Grams CaO for Leached Liquor From 100 G. Concentrate, per Cent
4	27.56	20.80	14.56	36.40
9	30.74	24.20	16.24	40.60
10	31.34	31.20	21.84	54.60

with the calcium molybdate. When this condition has been satisfied, the resulting solution will be found to be only slightly alkaline, due principally to the small amount of calcium hydroxide still in solution. When this solution has been boiled and agitated vigorously, until the precipitate has become granular in appearance, it will settle quickly and can be easily filtered and washed. Only a trace of molybdenum will be found in the filtrate.

The total alkalinity of leached liquors from 40 g. of wulfenite concentrate obtained in runs 4, 9 and 10 gave total alkali equivalents in grams as indicated in Table VI; the alkalinity being first determined as total Na_2O , and then calculated as the chemical equivalent Na_2CO_3 , NaOH and CaO .

From several experiments made, it was found that the amount of CaCl_2 solution required, figured in equivalent terms to CaO , to completely precipitate the molybdenum, was only slightly more than the amount of calcium chloride necessary to combine with the hydroxyl and carbonate radicals.

The figures for CaCl_2 requirement for precipitating calcium molybdate in an alkaline solution are best found by calculating the strength of the CaCl_2 solution in terms of equivalent of CaO , and then adding enough of this solution to correspond to the amount of CaO required, as measured by alkalinity tests illustrated in Table VI, last column. If an excess of CaCl_2 solution is added beyond this equivalent CaO requirement, it will remain in the filtrate solution as the chloride. The filtrate from such a precipitation will be found only slightly alkaline, indicating that the alkalinity had been reduced down to the limits allowed by the solubility of calcium hydroxide, and that the molybdenum had been completely precipitated as calcium molybdate.

GRADE OF PRODUCT

The grade of product produced can be governed by neutralizing most of the free alkali before the addition of calcium chloride, in which case less calcium carbonate and hydroxide will be precipitated with the molybdenum. No attempts were, however, made to improve the grade of precipitate obtained, although, aside from the above suggestion, this could be further improved by ignition, which would decompose the hydrate and carbonate of calcium, leaving only calcium molybdate and calcium oxide. A composite sample from the calcium molybdate precipitates obtained in the experiments, dried at 100 deg. C., gave the following analysis:

	Per Cent
CaO	48.15
MoO_3	28.65
Mo.....	19.10
As.....	0.17
S.....	0.48
P.....	None
Si.....	Trace
Fe.....	
Al.....	
H_2O and CO_2	Not determined

In the original concentrate the ratio of As to Mo was 4.16 to 100, while in the calcium molybdate it is 0.89 to 100, indicating that 78 per cent of the arsenic and all the phosphorus had been eliminated in the leaching and precipitation steps in producing calcium molybdate.

The above grade if ignited would produce a product assaying approximately 37 per cent MoO_3 . Although the presence of arsenic, phosphorus and sulphur are objectionable in ferro-alloys, the purchasers of ferro-molybdenum vary in the penalty for their presence. Some will allow 0.5 per cent total P, S and As, while others will allow only 0.2 per cent. The removal of sulphur can be accomplished by an excess lime charge. A calcium molybdate obtained from a concentrate carrying a smaller amount of barite than was contained in the material experimented on would in all probabilities carry down but a very small percentage of sulphur. Arsenic or phosphorus, if in considerable amount, can be eliminated from the alkali leach liquor as described by Fester,* or by adding an oxidizing agent such as NaOCl and then a magnesium salt. Further, some arsenic can be driven off in the electric furnace, and it has been stated that some can be further removed

*Loc. cit.

by a refining charge, such as ferric oxide and sodium carbonate. The details for grading up the product and eliminating the small amount of impurities can be worked out for each particular grade of ore treated.

A qualitative run made in a small electric furnace, using a charge of CaMoO_4 , silica, iron oxide and carbon, gave very promising results. A button of ferromolybdenum was easily made which could be poured from the furnace; the odor of arsenic fumes during the run indicated some volatilization of this element. In making ferromolybdenum, molybdic oxide obtained by roasting molybdenite concentrates was used in crucibles before the introduction of the electric furnace, but the purity of such a roasted product in regard to As, P and S is often inferior to the calcium molybdate made in the foregoing experiments. Besides MoO_3 , a ferromolybdenum charge is usually made up of lime, ferric oxide or iron scraps, and some reducing agent like resin, charcoal, coke or aluminum. Silica is often-times added for fluxing purposes, and in some cases silicon element has been used as a reducing agent. Calcium molybdate then is an ideal product, since it contains MoO_3 and CaO , which are required in the furnace charge. Ferromolybdenum is now being made directly from molybdenite in the electric furnace with carbon and a large excess of lime along with iron ore or scrap-iron, since the sulphur can be readily slagged as calcium sulphide with a charge of excess lime.

COSTS OF A FUSION PROCESS

The following estimated value of products and cost of chemicals is based upon a 90 per cent recovery of lead metal and molybdenum as calcium molybdate. Although the recoveries for lead and molybdenum on Run 9, Table V, which run will be taken for the basis of calculation, represent an extraction of 96.70 per cent molybdenum and 98.50 per cent recovery of lead, the actual recoveries on a large scale would probably be less.

ESTIMATED VALUE OF PRODUCTS—BASIS ONE TON

4.53% lead, 890.6 lb. (90%), 801.5 lb. at \$5 per cwt	\$ 40.08
3.85% Mo,* 317.0 lb. (90%), 285.3 lb. at \$1 per lb	285.30
Total value of products	\$325.38

* Molybdenum in the final product as calcium molybdate; price for this element in crude concentrates varies from 75¢ to \$1 per lb. content

COST OF CHEMICALS

400 lb. Na_2CO_3 , soda ash, at \$2 per cwt	\$8.00
1000 lb. NaOH , caustic soda, at \$2.50 per cwt	26.50
100 lb. coal or charcoal, best grade, at \$8 per ton	40.00
1605 lb. CaCl_2 , fused lump, at \$25 per ton	20.00
Total cost of chemicals	\$54.90

† 1605 lb. CaCl_2 , equivalent to 812 lb. CaO , amount required to precipitate molybdenum from leached liquors from one ton of fused concentrates.

To the above must be added the cost of mining and milling sufficient ore to produce one ton of concentrates of the grade used in experiments. This is dependent upon so many factors and local conditions that no attempt at an estimate will be made here. Wulfenite ores have been mined and milled for their gold and silver content; consequently, in such cases, wulfenite concentrates could be cheaply produced. This has been well illustrated by the concentrates produced from the Mammoth dump. The ore from the Mammoth mine was originally treated for its free gold content, said to have been \$6 to \$7 per ton. The dump tailings from these treatments were later concentrated for the wulfenite alone. Horton states that the cost of concentrating wulfenite ores by wet processes is in general comparable to those of treating ores of galena,

sphalerite, chalcopryrite, etc., by similar methods. No estimate can be made on the cost of treatment per ton for labor, overhead expenses, depreciation, etc., involved in a chemical plant treating such material, as these items are variable and depend upon local conditions.

It can be said, however, that the demand for molybdenum and the market price will have more to do with the future of wulfenite than any other factors. If the price paid for molybdenum does not warrant a sufficient margin of profit for the extra expense involved in smelting, extracting and recovering the molybdenum as calcium molybdate, then the wulfenite concentrates will be treated for their high lead content alone, or remain unused.

Considering the difference of \$270 between the estimated value of products and the cost of chemicals for one ton of concentrates, it appears that there is sufficient margin to take care of all expenses involved in the mining, milling and metallurgical treatment.

In conclusion, the author wishes to express his appreciation and gratitude to Dr. R. B. Moore, superintendent of the Rocky Mountain Station of the U. S. Bureau of Mines, for his valuable suggestions throughout the progress of the work.

Golden, Colo.

Sheet Zinc Stencils

Rolled zinc has desirable characteristics not found in other materials used for making stencils and will have extensive commercial use. This is the gist of a statement made by William L. Muehler of the Patent Die & Stencil Works, New York City. In view of this concern's wide experience in making stencils, the opinion of its representative is regarded as important to the industry.

"Not only is zinc the only material that does not stretch and buckle in continuous use, but it has several other important advantages," says Mr. Buchler. "The oil board used up to now for stencils certainly is low in price but the cutting and making of a paper stencil involves the same skilled work as a stencil made of zinc, and while the former hardly will give 20 to 25 impressions or reproductions a zinc stencil will reproduce 10,000 copies.

"Zinc remains flat indefinitely. Another feature that recommends the use of zinc is the low cost of producing the finished stencil, this metal possessing qualities that permit stamping as many as 1000 stencils in one operation.

"When the manufacturer realizes the economy and value of zinc stencils, as compared with others, it will mean vastly increased demand for this metal. Stencils form the background of nearly every manufactured article—from laces to showcases.

"Right now negotiations are being carried on to supply Japanese producers with zinc stencils for use in stamping silk designs to replace the slower and more expensive hand methods now in vogue."

The Allen-Moore Cell in the Pulp and Paper Mill

Description of the Chlorine Bleach Department in the Paper Mill of Dill & Collins Co.—Brine, Cell, Evaporator and Bleach Room—Diaphragm Cell Construction—Summaries of Operating Reports—Present Installations

By F. H. MITCHELL
Chief Chemist, Dill & Collins Co.

THERE is a decided tendency among progressive pulp and paper manufacturers to control so far as possible the production of their own raw materials, not merely for the purpose of the extra profit, but for the security realized in times of commercial stress and bad railroad conditions, and for securing a uniform product. Many of the large pulp and paper mills manufacture their own bleach electrolytically, not only for the reasons mentioned above, but because, added to the advantages of greater economy and security, there is the benefit of a product which is more active chemically. Many manufacturers claim actual savings in bleach consumption amounting to from 10 to 20 per cent, but the question as to whether a pound of available chlorine in a solution made from commercial bleaching powder is the equal in color produced to a pound of chlorine in electrolytic bleach liquor has been the subject of much discussion. There is, however, no question that the electrolytic bleach solution is quicker in action, and that it is possible to get a solution free from suspended lime, avoiding at the same time the losses which are incidental to getting the bleaching powder into solution. These losses are frequently more serious than is supposed. Actual tests in mills have shown losses from 2 to 20 per cent, the results varying with the quality of the bleach and the carefulness of the men.

In view of this situation, it is believed that a description of the electrolytic bleach plant of the Dill & Collins Co., of Philadelphia, is of interest. Its first cell installation was started in operation on Sept. 16, 1916, and has been in steady, successful operation since that time.

It consists of one series of 1200-1500-amp. Allen-Moore cells, which are operated ordinarily at a load of 1200 amp. These cells were designed by the Electron Chemical Co., and the plant and auxiliary equipment were designed by the Moulton Engineering Corporation, both of Portland, Me.

The accompanying photographs show the different parts of the plant and make detailed description unnecessary. Although but 62 cells were installed at first, a 2-story cell house was built, with a view to further

ALLEN-MOORE CELL, WITH RECTANGULAR LEADING-IN RODS

growth, and the second series of cells was installed in 1918, together with 128 cells in a separate cell house, the increase being for the Chemical Warfare Service.

The Dill & Collins bleach plant is naturally divided into the following departments: Brine room, cell room, evaporator room, bleach room and power; and for the sake of clearness these subdivisions will be considered in order.

BRINE ROOM

The first essential for the successful operation of a diaphragm cell is a brine freed not only from dirt and insoluble matter, but also from calcium and magnesium compounds. In the Dill & Collins plant the salt is carried by a conveyor to the reinforced concrete saturating column, which is kept full of salt. Water enters at the bottom and overflows at the top, the rate of flow being so regulated that a continuous flow of saturated brine issues from the top of the saturator, whence it flows by gravity to concrete purifying tanks. Here soda ash is added, with air agitation, time being allowed for the precipitation of impurities. The contents of this tank with its impurities in suspension are run through a sand filter, so constructed as to be easily washed and cleaned. The clear brine flows into storage tanks, where hydrochloric acid is added in sufficient amount to neutralize any excess of alkali. The purified brine flows by gravity

ALLEN-MOORE CELL WITH ROUND LEADING-IN RODS

SHOWING THE EASE WITH WHICH THE DIAPHRAGM MAY BE CHANGED ON THE ALLEN-MOORE CELL

into a small flow box, the brine being kept at a constant level by a hard rubber float valve, and from this flow box the brine is fed to the cells. Each tank of purified brine holds 12 hours' supply of brine, so that little labor or close attention is required in the brine room.

A good quality of mineral salt (frequently testing 98 per cent NaCl) requires small quantities of soda ash. There is rarely sufficient magnesium present to require special treatment, and the sulphates are seldom present

Zaremba evaporator, 84-in. pans, with two salt filters under the second effect. The salt caustic liquor to be evaporated contains approximately 120 g. NaOH per liter, and in the two effects is concentrated to a caustic solution of about 46 deg. B. The salt precipitated by the concentration of the liquor is caught in the filters, where it is washed to free it from caustic, and then returned to the brine system. The wash-water, collected in a storage tank, is subsequently returned to the evaporators.

CELL HOUSE NO. 2, DILL & COLLINS CO.
PHILADELPHIA, PA.

The concentrated caustic, cooled to permit the deposit of any suspended salt, is used in the pulp mill for cooking the wood, or is sold in liquid form. The finished caustic liquor contains on the average $1\frac{1}{2}$ per cent of salt.

BLEACH ROOM

The tower system is used, the equipment consisting of two concrete towers, each with a partition in the middle, and a series of concrete tanks, with agitators. Each tank holds sufficient milk of lime to make the equivalent of two tons of 35 per cent bleach, in the form of a liquid carrying the equivalent of approximately 80 g. 35 per cent bleaching powder per liter.

The milk of lime in the tank is raised by a centrifugal pump to the top of the towers, down which it falls in a spray, thus absorbing chlorine, which is drawn upward by a fan. The liquor returns to the tank by gravity and is recirculated until it has reached the strength desired. In order to avoid chlorating, an excess of lime is

CELL HOUSE NO. 1, DILL & COLLINS CO.
PHILADELPHIA, PA.

in an amount to necessitate precipitation. Careful tests are made to insure a supply of properly purified brine for the cells.

CELL ROOM

Each Allen-Moore cell, of which a detailed description follows, carries a float valve operated in a brine well, so that the proper level of electrolyte is maintained. By a simple device, the level can be raised as the diaphragm becomes clogged, to keep the flow at the required rate. The cells are arranged in two rows, electrically connected in series.

The caustic soda effluent flows from the front of the cells into a tile main, and the chlorine from each cell enters a tile main on which a slight vacuum is maintained by a suction fan. The hydrogen gas is discharged into the atmosphere.

The evaporator room is equipped with a double effect

INTERIOR OF CELL HOUSE, ILLUSTRATING ARRANGEMENT OF CELLS

SECOND INSTALLATION DILL & COLLINS CO.

maintained at all times. When one tank is finished, a second tank of milk of lime is cut in, and the first tank is allowed to settle. After the clear bleach liquor has been decanted to the pulp mill, fresh lime is added to the empty tank and it is ready for a second run. At intervals of ten days or two weeks, depending on the purity of the lime used, the sludge from each tank is washed into the sludge tank, and the residue, consisting of silicates and other insoluble matter, is thrown away.

It is important that the lime be as free as possible from magnesium, since otherwise the bleach will not settle quickly, and it will become increasingly difficult to recirculate the residue. The chlorine apparently does not combine with magnesium until after the calcium has been used up, with the result that there is an accumulation of magnesium which proves disastrous to the keeping qualities of the bleach and to the efficiency of the process. A particularly careful study of the effects of magnesium compounds, as well as iron and manganese, was made by Messrs. Martin Griffin and John Hedalen, the results having been published in the *Journal of the Society of Chemical Industry*, May 31, 1915.

In this installation the current for electrolysis is furnished by generators direct connected to reciprocating engines, and the layout does not call for special description.

DEVELOPMENT OF ALLEN-MOORE CELL

On account of the interest created by the operation of the Allen-Moore cell, a full description of its development and operation follows:

The Allen-Moore cell is not new, for its inception dates back to 1895, when Hugh K. Moore and Edward A. Allen were co-workers in the first commercial electrochemical plant in the United States, established in Rumford, Me., after the plans of Ernest LeSueur and Charles N. Waite. Indeed, this plant was the starting point of the development of the electrolysis of salt, and most diaphragm cells can be traced to this beginning. The story of the trials experienced in this plant is intensely interesting and should some day be told.

Besides Moore and Allen, above mentioned, were other men whose names have become well known in connection with electrolytic cells. Among them were MacDonald, Barton and others who have been responsible for a great

deal of the development which has been made, and the results of the work of the four men above mentioned is seen in practically every diaphragm cell now in successful operation.

The first installation of the Allen-Moore cell in its present form was completed in May, 1912, in the pulp mill of the Jessup & Moore Paper Co., Wilmington, Del., and the plant has been in steady successful operation ever since. The Jessup & Moore Paper Co. made a second installation in 1916, in its mill at Elkton, Maryland.

CONSTRUCTION OF CELL

The Allen-Moore cell is a porous diaphragm cell with one face only of each diaphragm in contact with the electrolyte and was the first cell to adopt this principle.

Referring to the illustration, it will be noted that the Allen-Moore cell consists of a rectangular frame of carefully placed reinforced concrete, formed by a base, two ends, and a chamber at the top, this latter being formed by the two side walls, the cell cover, and that portion of the cell ends between the side walls.

It should be realized that this reinforced concrete body serves as an insulating medium to separate the product of the anode compartment from the cathode compartment, and experience has shown that it has decided advantages. It is easily cast and it is so cheap that the total yearly cost is a very small item per ton of products. Moreover, the construction permits the accessibility which is one of the features of the cell, and is one of the factors in the high operating efficiency. The concrete bodies in the Dill & Collins plant are in excellent condition today, after being in constant use for nearly three years.

The arrangement of base, ends and chamber forms an opening in the cell body which, when closed on each side by the diaphragms and cathode chambers, constitutes the space for the electrolyte and the cell anodes. These graphite anodes are disposed in this space in such a manner that their active surfaces oppose the surfaces of the diaphragms which, backed by perforated cathode plates, cover the openings in the cell body. The arrangement of anodes, diaphragms and cathode plates is such that the asbestos diaphragms lie against the cathode plates, while between the diaphragms and active anode surfaces there is a clearance of approximately one-half inch. The electrolyte of saturated brine fills

CONCRETE BRINE TANKS

CAUSTIC POTS

this space between the anodes and diaphragms and covers the anode plates. The anodes extend through the electrolyte chamber, through the gas chamber at the top of the cell and the cell cover, and they are connected to the copper bus bar running along the top of the cell.

The brine is admitted to the anode compartment of the cell from the iron brine main through wrought iron pipes, which are connected with a hard rubber float valve which automatically controls the level of the brine in the well located in the center of each cell and maintains a constant level in the anode chamber.

The brine in the anode chamber comes in contact with the immersed graphite anode and one face of each asbestos diaphragm, of which there are two, one on each side of the anode chamber. The chlorine gas generated in the anode chamber is discharged from each cell into the tile chlorine main at the rear of each bank of cells by means of a tile U with luted connections on both the cell and the chlorine main.

TABLE 1—DAILY SUMMARY

24 Hr. Ending at 7 A.M., Jan. 18, 1917

Number of cells running	53
Average voltage at switchboard	200
Average amperes	1,200
Deliveries to Mill:	Total
Pounds, 35 per cent bleach	10,997
Pounds of caustic soda	4,520
Chemical Tests:	
Grams total chlorine per 1,000 cc	84.15
Grams 35 per cent bleach per 1,000 cc	1.72
Grams free line	
Caustic Soda:	Grams per 1,000 cc.
Effluent from cells	NaOH NaCl
Finished product	140 163
	713 17.52
Efficiencies:	
Current efficiency, per cent	94.05
Decomposition efficiency, per cent	55.75
E. h. p. per ton of bleach	58.60
Per cent salt recovered	

The brine, percolating through the permeable asbestos diaphragms, which are supported against each open side of the cell body by means of perforated wrought iron cathode plates, is decomposed and flows down the face of the cathode plates into the channel trough of the steel frame cathode box and deposited there in the form of a salt caustic solution containing about 12 per cent salt and 8 to 10 per cent caustic soda.

As typical of the operation of the cells, a copy of a daily summary of plant operation (Jan. 18, 1917), showing the data kept is given in Table 1.

On Feb. 2, 1917, after the plant had been in operation since the preceding September, an official 24-hr. test run was made. Each cell was tested for voltage and current efficiency at 6-hr. intervals, with the following average results:

0. Cells in operation	54
1. Active cathode area, sq. ft.	24.12
2. Amperes per cell, average	1,200
3. Voltage drop on individual cells (average)	3.6
4. Current efficiency based on four tests at 6-hr. intervals, on caustics	95.3
5. Caustic soda per cell, lb.	91.7
6. Voltage drop on cell circuit	292
7. Saturation of electrolyte, grams NaCl per liter	305
8. Decomposition efficiency, per cent	55.1

It is of added interest to note that other installations of the Allen-Moore cell are operating with similar good results. Five different plants were the subject of tests not long ago, and the summary of their tests is given in Table II.

The energy efficiencies in the last column of Table II are derived in the following manner (illustration taken from the data of Plant No. 5):

$$2.3 \text{ (theoretical voltage)} \div .96 \text{ (current efficiency)} \times 100 \\ = 59.6 \text{ total energy efficiency}$$

It will be noted that, in compiling the results of the tests, a distinction is made between voltage efficiency and total energy efficiency.

The actual average power required for producing 1 lb. of chlorine in the five separate plants considered is, therefore, 1292 kw.-hr.; derived in the following manner:

$$1344.2 \text{ (average amperes)} \times 0.00290 \text{ (lb. theoret-}$$

DOUBLE EFFECT EVAPORATOR WITH SALT FILTERS

ical chlorine per ampere hour) $\times 0.9477$ (average current efficiency) = 3.9 lb. chlorine per cell each hour.

$1344.2 \text{ amperes} \times 3.55 \text{ average voltage per cell} = 4.77 \text{ kw.}$

$4.77 \text{ kw.} \div 3.9 \text{ lb.} = 1.292 \text{ kw.-hr. per lb. of chlorine.}$

TABLE II—PLANT TESTS UNDER ACTUAL COMMERCIAL CONDITIONS

	No. Cells	Average Amp.	Average S. B. Volt.	Voltage Efficiency	Current efficiency per cent	Energy efficiency per cent	Notes
Plant No. 1	31	1362	3.32	69.27	95.00	65.8	Official — Tests run about one month after cells were put in operation.
	31	1226	3.33	69.06	96.47	66.5

PRODUCTS ARE EXCEEDINGLY PURE

It is obvious to those acquainted with the electrolytic chlorine industry that the products of the Allen-Moore cell must be exceedingly pure. The high current efficiency is sufficient proof of that. The chlorine is entirely free from hydrogen, and contains merely air and small amounts of CO_2 . The purity of the caustic is best attested by the long life of evaporator tubes, different

BASE OF GAS ABSORPTION TOWERS

effects frequently running more than two years without replacing a tube, and the fact that the caustic is almost entirely prevented from entering the anode compartment is proved from the fact that the anodes, operated at 1200 amp., have an average life of 18 months.

The voltages in the column illustrate the effect of different loads. At 1200 amp., with new diaphragms and new anodes, the voltage is approximately 3.3, increasing slowly to 3.5 or 3.6, when the diaphragm becomes plugged. The maximum voltage under this load is reached at 18 months, when the anodes require replacing. This maximum voltage averages 3.8. Each time the diaphragms are changed the voltage drops. After the first change, at the end of 3 months, the voltage will be nearly the same as with the new cell, but with subsequent change, as the anode wears, and the electrode distance increases, the initial voltage is higher until, at the end of the graphite cycle, a maximum voltage of 3.8 is reached.

A diaphragm life of much longer than three months can be realized, but with a loss of output per kw.-hr. The diaphragm change and the washing of the cell can be accomplished with so little labor (the regular cell attendants taking care of changes) that the increased output makes the use of more asbestos profitable.

The economical operating load of this cell naturally varies with local conditions and with power cost. It will yield almost equally good results in output over a range of from 900 amp. to 1500 amp. In fact recently, in a test at one installation, cells were operated for a period of 6 weeks at loads varying from 1500 to 1900 amp., at a voltage of 4.5, and with a current efficiency of from 90 to 92 per cent.

BLEACH INSTALLATIONS

It is evident from the results secured in the Dill & Collins Co. plant and in others where this type of cell is used, as well as in pulp and paper mills where other types of cells are in successful operation, that the electrolytic manufacture of bleach has long since passed the experimental stage. There is no guesswork as to what a cell or the auxiliary equipment will do. Given definite premises as to cost of power, raw materials and labor, it is possible to fix the production cost of bleach and caustic soda just as accurately as the cost of pulp can be figured.

TOPS OF GAS ABSORPTION TOWERS AND LIME-MIXING PLANT MAKING BLEACH LIQUOR

Following is a list of the pulp and paper mills producing their own bleach:

Americanization Work in Newark, N. J.

THE sculptor Rodin was a good deal of a prophet. Most of us know his statue "The Thinker"—which is not a white-bearded old man resembling the Rev. Lyman Abbott at all. This thinker is young, he is nearly all muscle and brawn; his brow is low, and he has never thought before. But he is thinking, is thinking now, and he is thinking very hard. With all the world a-quiver with emotion, and history that none of us can understand seething in the making, in the melting-pot before us, everybody tries to think—and the man of muscle and brawn is no exception. He is trying his best, but it is not at all certain whether he will think right or wrong—with the general welfare in view, or toward the red riot of calamity as an end. He will, however, think very much as he is led. The mere presence of a leader may be a determining factor. If, then, the only one present is an I. W. W. organizer, the thinker is likely to follow him, and in the end to range himself among the powers of evil and against all government and order. But if there is any one present to teach him the ideals and ways of American citizenship, the chances are that he will follow such a leader by preference, because most men prefer law and order to chaos. On the other hand, he will not follow any leader who is not in earnest for reasons that are too obvious to need exposition.

NEWARK'S INDUSTRIAL EAST SIDE

The manufacturers of Newark, N. J.—or some of them—have grasped this fact, and, being men of imagination, they have become alive to its significance. Now the purpose of this paper is to tell what has happened in the industrial east side of the city which contains a great many chemical works and a shipbuilding yard which alone employs some 15,000 men. The phenomenon is not peculiar to Newark; doubtless other places have done as well, and some may have done better. But Newark is near by, it is in earnest, and we feel related to it by many ties of chemistry. So let us discuss Newark.

The so-called Ironbound District extends from the Pennsylvania Railroad tracks to the shore of Newark Bay. It covers about three square miles, and some 203 industrial establishments are housed within its boundaries. These employ about 40,000 persons. The total population is 62,189, while those of foreign birth and their children constitute 50,392. There were, according to the last census, 11,807 foreign-born males of voting age, of whom only 3048 had been naturalized. And there were 4588 illiterates of 10 years and over.

In regard to the people who live and work in the Ironbound District, up to a year ago nobody had been very much interested in them. They were not fashionable, nor were they picturesque. Nevertheless, they went right on living, and increasing, and multiplying. And when the thinker of the Ironbound District put his hand over his head and began to think, he was reached by the following organizations:

INFLUENCE OF VARIOUS ORGANIZATIONS

His church and his priest. The purpose of these is to hold him to ethical standards, which is a good thing. The hold, however, is often frail.

The yellow newspapers. These preach the gospel of hate and discontent, usually with a political end in view, or to enlarge their circulation. They prepare the way for I. W. W. propaganda.

The labor unions. With their present passion to unionize everybody and everything, the labor unions have loosened up in their discussion of ideals of betterment, and have substituted problems in economics for consideration among their members in the place of problems in the art of living. This is of no help to the man who is not advanced beyond the stage of elementary thought; in fact it is more likely to upset him than to aid him. It is a great mistake to neglect the art of living as of first consideration, because the subject of economics will begin to manifest itself as soon as proficiency in the art of living has been attained.

RADICALS PREACH REVOLUTION

The I. W. W. and the Left Wing Socialists tell the thinker that he is the slave of Capitalism; that the world is divided into two great hostile camps, of which one gets the rich proceeds of all the harvests and growth, while the other gets only the poor leavin's; and that it is only by a mere fiction of possession that the rich hold their property. The gospel is preached that the only way for the poor man of today to achieve abundance is by revolution; by a regular invasion of the lands and estates of the minority rich by the majority poor. The methods are very much the same, whether expounded by Left Wing Socialists, I. W. W., Bolsheviki, or any other section of the angelic choir; the main differences have to do with who shall lead the crowd, and who shall divide the swag.

There's no profit in getting excited over it. A better way of understanding it is to imagine what we should do—we and our friends—if we were Estonians or Yugoslavs or Transylvanians, with a language of which the native-born Americans are grossly ignorant. Suppose we worked by the day in the Ironbound District, and that we had difficulty in learning this amazing English language with its ridiculous and impossible pronunciation. Supposing practically nobody on the continent except people from back home could talk to us. Suppose we had no decent books or papers, and were restricted to a pathetic little weakly weekly newspaper, printed in our own language as much for those who can't read as for those who can. We should know only the ugly side of the town, and the chances are we should show only the ugly side of ourselves.

NEWARK MANUFACTURERS TAKE ACTION

It was in October, 1918, that Newark seemed ripe for propaganda and the brotherhood in Russia went so far as to send a number of their slumbering not nor

sleeping Bolshevik organizers to establish headquarters right in the Ironbound District, where a large number of Russians live. And it was then that a number of Newark manufacturers got together. It is not recorded who said what, or just who made the next move, but the fact is there was soon developed and organized a concern which is known as "The Ironbound Community and Industrial Branch of the Y. M. C. A. of Newark." The organization has its own officers, and it minds its own business. It gives the impression of being free from that element of the Y. M. C. A. which is addicted to white lawn ties and to prayer meetings and revivals. Mr. A. V. Hamburg of the Hamburg Button Co. is president. Associated with him on the executive board are Messrs. J. H. Bacheller of the Ironbound Trust Co. and F. W. Volk of J. H. Ladew Co. Of the committee of management Mr. Volk is chairman. The vice-chairman is Mr. Eugene Merz of Heller & Merz Co.; Ex-Senator J. H. Bacheller is treasurer; John Campbell of Maher-Flockhart Co. is secretary, while the other members are Messrs. Joseph Doyle of W. S. Rockwell Co., S. C. Coey of Celluloid Co. and W. F. Mullin. A number of these names will probably be familiar to many of our readers. Mr. Edward B. Jacobson, 203 Essex Building, Newark, is the executive secretary. He is an alumnus of the University of Nebraska and of the School of Civics and Philanthropy of Chicago. He has been engaged in social and welfare work for several years in Chicago Stock Yards, in Pittsburgh, and with the du Ponts.

The next step was to organize, which was easy since these men of business wanted to. They didn't want to raise a little Russia right there in Newark; and while they are nearly all ambitious manufacturers they did not want to add *bad Americans* to their products.

MEETINGS HELD IN FACTORIES

Mr. Jacobson secured from the Prudential Life Insurance Co. and the New Jersey Law School some thirty young men who were soon trained to teach English and citizenship. They were volunteers, and they bit right into the work. Another thing was to visit the priests of the various foreign-language churches, mostly of the Roman and Greek Catholic persuasion, and these, to a man, were hearty in their co-operation. At this time Mr. R. I. Vail, who has had some fourteen years of experience in Americanization work, was added to the supervisory staff. Then meetings began all over—in factories, sometimes as part of the lunch hour, and sometimes after closing; sometimes on paid time, and sometimes on the men's own time; they work it every way, but principally in two directions: teaching English through the Peter Roberts system, and citizenship. The English classes go right on, with new ones forming constantly. In the meantime various foremen in factories have taken the teaching course, and they are now teaching also. The citizenship meetings, classes and lectures disclosed the remarkable phenomenon that Bolshevism, I. W. W. propaganda and the like were the only ideas that theretofore had been propounded. The idea of representative government appealed to them as soon as they could understand, and the appeal of revolutionary ideas lost force as soon as others were placed in competition. To those who love system and order the appeal of revolution and disorder is not strong.

Illustrated talks on government were introduced, and

these have been carried on in various languages. Open forums are held, and at one of them lately, attended by 600 Russians, the speaker of the evening, who had recently returned from Russia, was invited to come again, to explain more fully the differences between the American ideals of democracy and those of the Russian Bolsheviks. Within the short time the work has been under way over 630 men have been aided in getting out their naturalization papers.

GRAND PAGEANT ON MEMORIAL DAY

Then on Memorial Day there was a grand pageant in which 10,000 people participated in East Side Park. There was a Parade of All Nations to Four Corners and back, and a silver loving cup given to the best appearing division. There were tableaux, and pledging allegiance to the flag, an address by the Mayor, and folk dances, with a silver loving cup as prize for the best dancers. Then followed addresses in English, Russian, Polish, Italian, Lithuanian and Czechoslovakian. That may not sound important, but in point of fact it was so; it was the first participation of those new citizens in a public affair. It had more meaning in it than any other Decoration Day parade that we know of.

It was the privilege of the writer to visit two classes in English at the Heller & Merz works. They began after the evening whistle blew, were held on men's time, and the energy and enthusiasm of the pupils were no less than inspiring. We need not be afraid of such men. They are workers, not idlers. The loose-lipped pervert and the swaggering high-class idiot were not among them. We may well welcome them as citizens. Their situation, however, is difficult. They do not yet know the language of the country, nor are they familiar with its customs. Few of them know anybody who has got rich, except by sight. Heretofore nobody has been interested in them except their own little group, and it has been difficult to determine where to seek good advice, or to know which advice was meant for the recipient's good, and which for the adviser's own profit. In the old days things were different, and a man could know his boss. Now that concerns have grown so big a man hardly knows his foreman.

This reminds us of another department about to be started in the Ironbound Community Service. It is a foremen's organization of different factories and industries. Who would have thought of that twenty years ago? Through this we may learn of exceptional talent occasionally. And the long day's work may be made into a thing desired.

GOOD AMERICANS THERE IN THE MAKING

The Ironbound District of Newark is not a fashionable quarter. But we believe there are Americans in the making there who may in time prove much more illumined leaders of us all than some of the most puffed up and vainglorious Senators in Washington today. The men are in earnest, the teachers are in earnest, the employers are in earnest, and social conditions have greatly improved since this movement has been under way. Maybe some day in addition to the reputation for high-class merchandise which the city of Newark enjoys there may be added the tradition that the men that came from Newark are upstanding and dependable; that they do not break faith; and that they bring with them ideals of fairness to all and of liberty through justice.

Commercial Testing of Metallurgical Electric Furnaces

A Comprehensive Outline of Methods to Be Used in Testing Metallurgical Electric Furnaces—Interpretation of the Collected Data, Summarizing the Results, Conclusions as to Suitability, Reliability, Production, Cost of Operation and Maintenance and Other Considerations

By H. M. ST. JOHN

DURING the past three years there has been a notable increase in the use of electric furnaces as applied to metallurgical processes, and the question of electric-furnace design and operation for various metallurgical purposes has become one of absorbing interest to many who previously had little knowledge of the subject. This development has not been without its publicity, but, among the valuable contributions which have filled so much space in the technical press, one searches in vain for a comprehensive discussion of suitable and adequate methods for use in testing furnaces of this type, for the purpose of determining their real economic value under any given set of conditions.

It is not the intention of the writer to attempt, in this article, the presentation of an authoritative and final exposition of testing methods, which might be accepted as a complete and trustworthy guide for use under any and all conditions. Desirable as such a conclusive statement of methods may be, it can result only from an open discussion, from different angles and by men of varied experiences, each of whom can contribute something not common to the experience of others. It is partly in the hope of arousing such a discussion that this article is written. If, at the same time, the results of the writer's experience prove to be of any value to others faced by similar problems, his purpose will have been completely served.

THREE FACTORS TO BE CONSIDERED

The consideration of an electric-furnace installation for use in a metallurgical plant naturally resolves itself into three parts. First, it is necessary to select for trial some type of furnace likely to give the desired results in the work of that particular plant. Second, the furnace chosen must be subjected to an adequate test, to determine the quality of its performance as compared with other types of equipment, electric or otherwise, which are suitable for use on the same work. Finally, the furnace, once accepted as satisfactory, must be fitted into its place in the manufacturing scheme of the plant by the development and use of suitable operating methods, designed to secure a maximum of operating economy with a minimum of expensive supervision.

The question of initial selection of the furnace, and that of development of operating methods, are reserved for later discussion. Let us confine ourselves here to a consideration of electric-furnace testing and the interpretation of test results, principally for the reason that this phase of the matter has so often been neglected, sometimes with serious results.

In dealing with the commercial testing of electric furnaces, as differentiated from laboratory testing incidental to their experimental development, it is necessary to remember that, as a rule, at least three parties have a vital interest in the successful use of the furnace. These are the seller of the furnace, the prospective user,

and the company which is to supply electric power for its use, or, if the manufacturing plant generates its own power, its power engineer may be considered as the third party. Each of these has important interests which must be satisfied, and no furnace test is complete which does not supply the necessary data to meet their varying requirements.

FAILURES SOMETIMES DUE TO LACK OF CO-OPERATION

The failure of certain furnace installations can be traced directly to a lack of co-operation among these three interested parties. In general, each has certain information and experience pertaining primarily to his own sphere of operations but having an important bearing, nevertheless, on the successful use of the furnace. The seller is familiar with the characteristics of his furnace, but is not likely to have complete knowledge of the requirements peculiar to the plant in which the furnace is to be installed, nor does he always realize the effect which these requirements will have upon the operation of the furnace. The manufacturer understands the necessities of his plant, but as a rule he is not familiar with electric-furnace operation and often does not understand that he can profitably modify the practice which he has previously adopted as suitable for use in connection with fuel-fired furnaces, in order that he may enjoy, to the fullest extent, the advantages of the electric furnace. Even if he is convinced that the methods in use in his plant should, so far as practicable, be made to conform with electric-furnace requirements, he himself, and his technical staff, are handicapped by lack of experience with electric-furnace operating methods. Neither the seller of the furnace nor the manufacturer who is to make use of it is likely to be aware of the special problems of electrical generation and distribution which must be solved in order that the power company may supply satisfactory service for the furnace at a reasonable cost, nor can they easily calculate what the cost of power will be under given conditions.

CENTRAL-STATION COMPANY OF ASSISTANCE

With respect to these points, the central-station company occupies a unique position in that its true interests are identical with those of both the seller and the buyer, while at the same time it usually has at its disposal information dealing with the application of electric furnaces which is more general and comprehensive—if less detailed and specific—in its nature than is readily available to either of the other parties. As a result the power company is in a position to render a great deal of assistance in the development and proper application of electric furnaces in the territory which it serves, and is the natural arbiter in case of misunderstanding or dispute concerning the nature and conduct of acceptance tests. It has, of course, its own interests to guard, but these do not in any sense conflict with those of the

furnace manufacturer and the buyer, who may be termed the "mutual customer."

General Outline of the Test

The ultimate object of a commercial or acceptance test of an electric furnace is to determine the quality of its performance with respect to suitability, reliability and overall economy. With any furnace these factors vary widely, depending upon the conditions of its use, and it is accordingly necessary to consider them afresh in the case of each new installation.

In order to prove its suitability in any given field, the furnace must turn out a product of at least as high a quality as that ordinarily produced by the industry, using the raw materials and operating under the conditions which the general requirements of the industry impose. Its performance must be at least as good, in all essential respects, as that of equipment already in use in the same plant or in similar plants.

Having met the requirements of suitability by showing a high quality of performance when at its best, the furnace must further demonstrate its ability to maintain its favorable performance, day after day, under average working conditions. Sustained mediocrity is preferable to intermittent perfection. A furnace which requires delicate handling, frequent repairs and expensive supervision is not a satisfactory industrial tool.

Finally, the electric furnace, in order to make a place for itself, must show that it has, in addition to suitability and reliability, economic advantages which will make its use a money-saving, money-earning proposition. It must not merely be as good as other equipment used for the same purpose; it must be better. It must either turn out as good a product more cheaply, a better one at the same cost, use cheaper raw materials, require less labor, show a substantially greater production for the same capital investment, or in some equally important way prove its economic superiority.

QUESTION TO BE ANSWERED

The electric-furnace test is expected to furnish the data by means of which these factors can be evaluated in dollars and cents, and an overall summation obtained for comparison with other furnaces. Other electric furnaces in other plants have proved that they possess some one or more of these advantages, and have consequently continued in successful operation; the question is: Can this furnace show that it has an economic right to exist in this plant?

The answer to this question lies in a thoroughgoing analysis of the furnace performance as related to plant operation, followed by correct interpretation of the results of analysis. It is the purpose here to discuss how this analysis can best be made and what form the interpretation should take, confining our attention to the various types of furnaces employed in the melting and refining of steel and non-ferrous alloys. These are the fields in which electric-furnace development is experiencing its most rapid growth and in which the practice of adequate methods of test is at present most needed.

In this class of work the data to be obtained from a comprehensive furnace test may be listed under the following heads:

1. Reliability and production.
2. Electrical characteristics.
3. Metallurgical characteristics.
4. Cost of operation.
5. Cost of maintenance.
6. Miscellaneous considerations.

The electric-furnace test proper naturally resolves itself into three parts: the preliminary test, the intensive test, and the operating test. These must sometimes be supplemented by various special tests to determine some one factor which cannot readily be studied under ordinary operating conditions. These three tests are of nearly equal importance, and no one of them can be omitted without seriously impairing the value of the test as a whole.

The Preliminary Test

DETERMINING THE FURNACE'S SUITABILITY FOR THE WORK

The preliminary test covers the period from the time current is first turned on until the furnace is operating smoothly under regular plant conditions. This period will ordinarily include from one to two weeks, although it may be much more prolonged. During this time what has been termed the suitability of the furnace will be determined. If it is entirely unsuitable for the work, this fact will at once become apparent. If the lack of suitability is inherent and ineradicable, the furnace test is at an end and the furnace is rejected without further ado. If, on the other hand, it seems probable that the difficulty can be remedied by minor changes of design, the test may be continued, depending principally upon how far the furnace user is willing to co-operate with the seller in carrying on what must really be classed as additional development work of an experimental nature. In any event, the intensive portion of the test cannot be started until the furnace is operating smoothly under practical rather than experimental conditions.

If no serious defects develop in the furnace itself the period of the preliminary test is utilized in testing the auxiliary equipment and in co-ordinating the operation of the furnace with that of the plant as a whole. Defects in auxiliary equipment, such as motors, regulating devices, charging and conveying mechanisms, are frequently troublesome, but can usually be remedied without serious difficulty. These must all be in proper condition before the furnace can be given a fair trial. The facilities for bringing metal to the furnace and for removing molten metal after pouring must be at least as good as those in use with other furnaces in the same plant. In fact, it is often true that electric-furnace operation justifies more complete and efficient equipment of this nature than could profitably be used with other furnaces.

CO-ORDINATION IMPORTANT

Co-ordination of the furnace with other parts of the plant is no less important and often more difficult in a long-established plant than perfecting the operation of the furnace itself. Elimination of waste time, always of importance, is absolutely essential to the successful use of the electric furnace. Everything must be ready when it is needed, and every man, from the furnace operator to the laborer in the pouring gang, must know exactly what is required of him and be prepared to carry through his part immediately, whenever his services are needed. The electric furnace cannot be fairly tested until the operator, the weighmaster, the boss of the pouring gang and the foreman of the casting shop are thoroughly familiar with this requirement and ready to comply with it.

The time occupied by the preliminary test can also be utilized to good advantage by those who are to take

an active part in the test, in familiarizing themselves with the conditions which must be met. The operator may already be familiar with the characteristics of his furnace, but he must also learn the characteristics of the metal which the furnace is to melt, and the specific requirements as to pouring temperature, etc., which the furnace must satisfy. The man who is to supervise the test, and his assistants, must acquaint themselves with the nature of the furnace and other equipment and must obtain a good working knowledge of the manufacturing methods in use in the plant in so far as these have a bearing on the operation of the furnace. If these men are not members of the plant organization, they should become sufficiently familiar with it and its personnel to insure full and willing co-operation at times when such co-operation is of vital importance. Under such circumstances personal acquaintanceship and good feeling are essential to success.

The data taken during the preliminary test are of minor importance and should consist of an approximate determination of the electrical characteristics of the furnace and of such general observations as are required in order to co-ordinate the furnace with the rest of the plant. This includes a determination of the approximate time required for the melting operation, for the charging, pulling the slag, pouring, etc., the weight and mixture of charge which gives best results, and other factors upon which the operation of the furnace directly depends.

Intensive and Operating Tests

DETERMINING BEST PERFORMANCE

The object of the intensive test is to determine the best possible performance of which the furnace is capable under the stipulated manufacturing conditions. A careful determination is made of all the factors which enter into the reliability and economy of furnace operation. This test normally requires from three days to a week, during which time skillful supervision and trained observation are necessary. It consists of a brief operating test, supplemented by such special tests as may be required, conducted in such a way as to establish standards of performance, with which the operation of the furnace later on, under more practical conditions, may be compared. The intensive test eliminates the personal equation of the human element so far as possible, and furnishes data which, if correctly interpreted, will demonstrate the virtues and defects of the furnace itself, as distinct from the men who are using it and the other foundry equipment with which it is used. Frequently these data will also point the way to improvement in design and modification of operating methods calculated to make of the furnace a more satisfactory foundry tool.

OPERATING TEST UNDER ROUTINE CONDITIONS

When the intensive test has been completed, unless the furnace has already exhibited defects so serious as to make its further use undesirable, it should be put to work as a regular part of the plant equipment and operated steadily in a routine manner for at least a month. This constitutes the operating test, the final stage of the acceptance test. During this period the taking of data continues, but operating supervision should be limited to the degree which would ordinarily be employed if the furnace already occupied an accepted place in the foundry. The operating methods used should be based

on the experience obtained during the preliminary and intensive tests.

The data taken during the operating test should include all points which have a direct bearing on the cost of production, but need not be so exact for each heat turned out as is desirable during the intensive test. The weight of metal melted and the kilowatt-hour consumption should be taken for each heat, as well as the time required for the melting operation; the metal lost in spillings and in the slag should be determined for the test as a whole, and, together with the weight of castings obtained, compared with the total weight of metal charged during the same period; the quality of metal and the percentage of defective castings, with the nature of the defects, should be carefully noted; irregularities in operation should be noted and traced to their sources; finally, the cost of maintenance should be determined as completely as is possible in such a comparatively short period of time.

COMPARISON OF FIGURES

At the conclusion of the operating test the results obtained under regular manufacturing conditions should be compared with the more ideal figures taken during the intensive test, for the purpose of establishing what may be called the best practical performance of the furnace. This comparison is also useful in pointing out defects in furnace construction or operation which may perhaps be remedied. It is now possible to predict, with a fair degree of precision, what may be expected of the furnace as a tool, and to determine its status as compared with other types of melting equipment, for which accurate data may be at hand. On the basis of this prediction the furnace may be definitely accepted, tentatively accepted for further development and test—if circumstances seem to justify such a course—or definitely rejected.

The series of tests described may seem to some unnecessarily comprehensive and detailed, but in the procedure outlined it is merely proposed to carry out, carefully and according to a definite plan, work which is more often done aimlessly or without due consideration. It is only by careful and thorough test that one may learn in a relatively short time what the electric furnace will do in actual practice. It is far better to obtain reliable information on this point before one pays for the furnace than to learn later on, from a perusal of the yearly balance sheet, that the furnace has been unprofitable.

Testing Equipment

SELECTION OF MEASURING DEVICES IMPORTANT

The selection and use of electric meters and other measuring devices is a matter of considerable importance in electric furnace testing. The permanent switchboard equipment of every electric furnace should include, at the very least, a watt-hour meter, to show the energy consumption of the furnace, and a voltmeter, to indicate the voltage across the furnace, if the latter is of either the arc or resistance type. In the case of the induction furnace the use of an ammeter, to show the current flowing in the primary circuit of the furnace, is perhaps of more importance. Ammeters are useful, in any case, especially with a 2-phase or 3-phase furnace, where it is desirable to detect any unbalancing of phases which may exist. An indicating wattmeter in the primary circuit enables the operator to tell at a

glance what his power input is, and is of distinct assistance to him. The use of a power-factor meter is advisable in the operation of any furnace which tends to have a low power factor, in order that the operator may be able at all times to keep the power factor at the highest practicable point.

RECORDING INSTRUMENTS A VALUABLE CHECK

Recording instruments are valuable as a check on the operator, especially in case of 24-hr. operation, where the plant superintendent seldom sees the night operator. A glance at the instrument chart will show the time taken for each heat and the characteristics of the load, while comparison of the chart with the operator's report will indicate the cause of trouble, if trouble exists. Not more than one recording instrument need be used for this purpose, usually either a wattmeter or a voltmeter, or, in the case of the induction furnace, an ammeter rather than a voltmeter.

For purely test purposes a voltmeter should also be used on the primary side of the furnace transformer, since a comparison between supply voltage and furnace voltage is desirable, particularly with arc furnaces. If the permanent equipment of the furnace does not include a power-factor meter, it is necessary either to provide such a meter during the test or to add a wattmeter and ammeter to the voltmeter already specified for the primary circuit, in order that the power factor of that circuit may be calculated.

CURRENT AND POTENTIAL TRANSFORMERS

These instruments must, of course, all be connected through suitable current and potential transformers. In the case of the watt-hour meter the ratios of these instrument transformers must be such that readings as small as one kilowatt-hour can be made with a fair degree of accuracy. It is only by a study of the energy consumption of the furnace during heats made at different times of day and under varying conditions that the highest economy of furnace operation can be attained. The watt-hour meter used by the power-supply company—upon the monthly readings of which the power bills are based—cannot ordinarily be read with sufficient exactness to be suitable for test purposes.

The temperature of the molten metal delivered by the furnace is of great importance, and, during the test period at least, should be known as exactly as possible. The metal should, of course, always be heated to the temperature required by the casting shop, but additional superheat is expensive and should be avoided, because the added energy required to produce even a few degrees of unnecessary superheat is relatively large. In melting brass or other alloys which contain a volatile constituent, unnecessary superheat also means unnecessary loss of metal and added expense on that score. Energy consumption and metal loss figures cannot be properly interpreted unless one knows the temperature at which each heat is poured.

The temperature of molten alloys up to 1250 or 1300 deg. C. (2280 to 2370 deg. F.) can be measured by means of a base-metal thermocouple, and such an instrument should be provided for this work. In the present state of the art the constant use of a thermocouple for registering molten metal temperatures in regular practice is often too expensive and inconvenient, but for test purposes the trouble and expense involved are well justified. Under these conditions the ordinary steel protecting tube cannot well be used, since it is rapidly at-

tacked by the molten alloy, and also because its thermal lag results in a slow reading. A bare couple gives rapid results which are fairly accurate if the determination is made with care. The couple is consumed rather rapidly by the action of the molten metal and its use is, therefore, somewhat expensive. It is not necessary to maintain the weld at the tip of the couple, since, if the elements are not allowed to separate widely, sufficiently good contact is made through the molten metal. Special protecting tubes may also be used, which, while rather expensive and having a tendency to retard the reading, are suitable for test purposes. It is usually more convenient to measure the temperature of the metal after it has been poured into the ladle rather than to attempt measurements of metal still in the furnace.

In the case of steel or other metals which are poured above 1300 deg. C. (2372 deg. F.) the problem of temperature measurement is an extremely difficult one, since the use of a thermocouple immersed in the metal is no longer practical. The use of an optical pyrometer, provided with a special temperature scale calibrated for the light emissivity of molten iron and steel, has been proposed, but such a pyrometer is very expensive and its value for this purpose limited. By installing a thermocouple permanently in some part of the wall or roof of the furnace it is possible to get relative temperatures which may be found useful. This practice is also advisable in the case of certain resistance furnaces which have a high capacity for absorbed heat, not so much for the purpose of estimating metal temperatures, but in order to limit the rate of heat input to a safe value.

The whole question of temperature measurement and methods is one which merits a much more detailed discussion than can be given it here. Its importance in metallurgical tests of all kinds can hardly be overestimated and it should be given careful study by the engineer who conducts such work.

OTHER INSTRUMENTS NEEDED

Other instruments needed for the electric furnace test are thermometers, stopwatches and a water meter, although the last named, while useful for determining the amount of water used for cooling purposes and for regulating the rate of water flow, can be dispensed with. Unless it is used, however, the amount of heat dissipated in the cooling water can be found only by weighing the quantity of water which passes through the cooling system in a specified time. A thermometer should be used to measure the temperature of the water supply, another to measure the temperature of the water as it leaves the furnace. The furnace transformer should be equipped with a thermometer to measure the temperature of its oil, and the room temperature in the immediate neighborhood of the transformer should also be taken. Stopwatches can be used to advantage in measuring various time intervals during furnace operation.

All instruments to be used during the test should be calibrated and tested very thoroughly, as inaccurate meters betray the confidence of the user and sometimes lead to serious errors.

Reliability and Production

Reliability and rate of production are closely linked, although the latter also depends, in marked degree, on the power input and thermal efficiency of the furnace. In judging reliability it is very important to make a distinction between delays in operation due to failure of

the furnace and delays due to lack of co-ordination between the furnace and other parts of the foundry. Interruptions in the continuity of furnace operation resulting from a failure of the weighmaster's department, or the casting shop, to meet the furnace requirements on schedule time are largely avoidable and should not be charged against the furnace. A distinction should also be made between unavoidable delays, resulting from defects inherent in the design of the furnace itself, and interruptions due to defective operation of auxiliary apparatus, such as tilting mechanism, electrode-operating devices, etc. These, together with such loss of time as may be due to lack of skill on the part of the operator, are also, for the most part, avoidable.

THE FURNACE LOG

Most of the information upon which conclusions with respect to reliability and production are to be based is contained in the furnace log. This log should be kept carefully throughout, from the time power is first turned on until the end of the operating test. In it should be noted the time interval required for each principal phase of the furnace operation, together with all irregularities and their cause, and such other happenings as may seem to have a bearing upon the performance of the furnace. In tabulating and interpreting the mass of data which must be digested, after the final test has been completed, it is often possible to explain puzzling and seemingly contradictory results by a glance at the log for the particular heat in question. The principal data for each heat should be kept in an orderly manner on a separate sheet, and, for the sake of convenience, should be unaccompanied by remarks or other extraneous matter.

SAMPLE OF A LOG

Following is given, as an example, a log for two consecutive heats of an arc furnace melting a copper alloy:

HEAT NO. 10	
Time A.M.	Remarks
3:25	Started charging
3:30	Power on
3:41	Power off to add new electrode
4:15	Power on
4:45	Power off to remove slag, metal ready
4:55	Started pouring
5:00	Finished pouring

HEAT NO. 11	
Time A.M.	Remarks
5:00	Started charging
5:10	Power on
5:20	Power off to adjust electrode
5:23	Power on and off immediately, broken electrode, new one added
5:28	Power on
5:32	Power off to adjust electrode
5:34	Power on
6:05	Power off because of changing shifts
6:12	Power on
6:14	Power off to remove slag
6:19	Power on
6:25	Power off, started pouring; spilled quite a bit in pouring
6:30	Finished pouring

The conduct of both of these heats is open to criticism, which, however, should not be directed toward the furnace. In the first heat 34 minutes was required to add a new electrode section, although the normal time for this operation was not more than 5 minutes, as was the case during the second heat. The man keeping the log neglected to note down the reason for the abnormal delay in the first case, a regrettable omission, as such delays are serious and should always be traced to their source. The loss of 7 minutes because of changing shifts was inexcusable. Such losses of time look small, when considered separately, but loom large when taken in the aggregate. On the day when these two

heats were made, the total of lost time, not in any way attributable to the furnace or its auxiliary equipment, amounted to 1 hour and 20 minutes, ample time for another heat to have been made. Examination of the data sheet for these heats showed that in each case the energy consumption was abnormally high, which was readily explained by the fact that the time consumed was at least 50 per cent more than necessary. The gross metal loss in Heat No. 11 was excessive, and a glance at the log gave the answer as "spilled metal."

LOG USEFUL IN MANY WAYS

The log, then, is useful in answering riddles propounded by eccentric data, but it serves an even more useful purpose in a way which has a direct bearing on the study of reliability and production. Its record should be analyzed and tabulated to show the manner in which time has been spent, usefully or otherwise. Time lost due to failure of the furnace, failure of the auxiliary equipment, lack of skill of the operator and dilatoriness on the part of other foundry employees can each be summed up and given its proper label as avoidable or unavoidable. It is then possible to judge the reliability performance of the furnace fairly and to estimate what production it is capable of giving if the avoidable delays are eliminated, or at least reduced to the point where added supervision brings diminishing returns.

Such a time analysis, made on the operation of an arc furnace in another plant, and covering a period of several days, showed the following conditions:

	Per Cent of Total Time
Time power on	57.1
Time power off	
Charging, pouring and pulling slag	20.2
Electrode adjustment and trouble	5.7
Motor trouble	3.1
Lunch period	2.2
Balance of time (wasted)	11.7
	42.9

By eliminating unnecessary superheating of the metal, arranging the operating schedule so that the furnace was not interrupted during lunch periods, utilizing time which had formerly been altogether wasted and reducing the time spent in electrode adjustment and for remedying troubles of various kinds from 8.8 per cent of the total time to 3.3 per cent, greatly improved results were obtained from this furnace. An average production of 19 to 20 heats per 24 hr. was raised to 24 heats, without changing the furnace in any way, and at the same time the operating cost per ton of metal was greatly reduced. This will illustrate the importance of analyzing the test results in order to credit the furnace with the performance of which it is really capable.

The nature of metal charged, especially its cleanliness and state of physical division, must also be considered in determining production. Ingots, chips and borings, thin scrap, heavy scrap, foundry gates and sprues, punchings, concentrate from the recovery plant, etc., will, as a rule, melt down much more rapidly if they are mixed with one another than if an attempt is made to melt any one class by itself. Borings or chips which are oily or wet are particularly troublesome if they are not mixed with cleaner metal in larger pieces. The production of the furnace must be estimated on a basis of the quality of charge which it will actually be called upon to handle. If test results are obtained under conditions which are either uncommonly favorable or peculiarly unfavorable, due allowance must be made for that fact.

Electrical Characteristics

The electrical characteristics, including power input, power factor and steadiness of load, play an important part in determining the output of the furnace, the rate which must be paid for electric energy and the desirability of the load from a central-station viewpoint. If the electrical characteristics of the furnace load are manifestly undesirable in any important respect, the central station may require the furnace user to install auxiliary equipment in order to modify and compensate for the objectionable features. Such equipment is likely to be expensive and must be taken into consideration in determining the installation cost and the investment charges. This applies particularly to large single-phase furnaces in a district supplied by 3-phase power, to furnaces which tend to have a low power factor and to furnaces which are subject to violent fluctuations of power. It is necessary to determine how these factors will influence the cost of power and of the initial installation in the district where the furnace is situated. It may, for example, be necessary to install a motor-generator set, or a phase converter, in order to improve the characteristics of the load; otherwise the power company may be compelled to isolate the furnace load by building a special line to the plant, in which case the manufacturer is likely to be called upon to deposit for a term of years part of the first cost of the new line. On the other hand, if a high-voltage power line, of large capacity and devoted exclusively to power business, happens to be conveniently located, even a single-phase, low power-factor load can be handled by the power company without serious inconvenience.

POWER INPUT

The average power input is measured by taking frequent readings on the wattmeter, or, if a recording wattmeter is used, may be integrated directly from its charts. This result should be checked against the energy input shown by the watt-hour meter. The variations in power input are also of importance; its maximum points and their duration should be noted.

The rate of power input has a direct effect on speed of production, and from that standpoint should be raised to the highest possible point. It is limited, however, by other considerations. For example, in the case of copper alloys, most of the constituents of which are somewhat volatile, too high a power input results in local overheating and excessive metal losses. Steel is not so sensitive, but the best furnace refractories available will not stand up against too rapid generation of heat, at the high temperatures of the steel furnace. In the induction furnace the power input, for a furnace of given size, is limited by still other considerations which need not be discussed here.

RATE OF POWER INPUT IMPORTANT

The rate of power input also has a direct influence in determining the rate paid for electric power. Power, in quantity, is almost universally sold on a schedule which bases the rate on two factors, the maximum demand, and the quantity of energy used. The demand charge consists of a fixed monthly rate per kilowatt of demand, and is in addition to the energy charge of a certain sum per kw-hr. used during the month. By maximum demand, in the case of an electric furnace, is meant the highest average power input, during a specified period of time, which has been recorded for the

furnace. The period of time taken as a unit of measurement is specified in the rate schedule of the power company, and varies, with different companies, all the way from 5 min. to 3 hr. The methods employed in measuring maximum demand also differ greatly. For example, in one city the maximum demand is taken as the highest average input during any 5-min. period which happens to be selected, and the determination is made with a watt-hour meter and a stopwatch. In another city the maximum demand is taken as the average input during any three individual hours which show the three highest averages, and the determination is made by means of a permanently installed instrument which records the input every 15 minutes.

The maximum demand so determined usually holds good for a considerable period of time (often 12 months) unless it is superseded during that time by a still higher demand, which, in its turn, becomes effective for a similar period. In determining the cost of energy to be used by the furnace it is evidently important to be in a position to predict what maximum demand the furnace will show under the particular rules and regulations which govern the sale of power in the locality where the furnace is to be used. The ideal power curve, from this standpoint, is a straight line, with a maximum average and minimum which are identical, an ideal which, of course, is not satisfied by any electric furnace.

The most desirable power input, under the given conditions, should be approximately determined during the preliminary test, and this value should continue to be used until a more suitable one is established by the intensive and operating tests.

POWER FACTOR

The power factor of resistance or induction furnaces may be measured by means of a power-factor indicator, or may be calculated from the readings of an ammeter, voltmeter and wattmeter. The power factor of an arc furnace may be roughly determined in the same manner, but frequent and violent fluctuations of the power input render it impossible to obtain a very accurate result, unless an average is taken from a large number of readings spread over a considerable period of time. These methods, imperfect as they are in the case of the arc furnace, are, nevertheless, the best means available for learning the variation in power factor during the changing conditions of a single heat, or for comparing separate heats.

When it is desired to determine the average power factor of the furnace during a period of a week or more, the sine-meter method is much to be preferred, and serves equally well with arc, resistance or induction furnaces. In this method two watt-hour meters, differently connected, are used, and, by the use of suitably plotted curves, power factor is calculated from the ratio of the reading of one instrument to that of the other. The method cannot be explained in detail here, but can be found, fully discussed, in standard works on electrical measurements.

In any case, power-factor measurements should be taken in the supply circuit—on the high side of the furnace transformer. The power factor in the furnace circuit is often much higher than that of the supply circuit, and the latter is the significant value.

Since a low power-factor load results in as great a demand on the current-carrying capacity of the power line as does a heavier load at a correspondingly higher power factor, the load with unsatisfactory power factor

is sometimes penalized by means of a higher demand charge. This penalty is applied in the case of all power factors below a certain specified minimum, usually in the neighborhood of 60 or 70 per cent.

DETERMINING POWER FACTOR UNDER DIFFERING OPERATING CONDITIONS

It is often desirable to learn what the power factor will be under differing operating conditions. This can best be done during the preliminary test, since, during later tests, uniform operating conditions are to be preferred. The curve in Fig. 1 shows the relationship between arc voltage and power factor in a high-voltage single-phase arc furnace. The power factor of this furnace was low and was subject to a penalty for all values below 70 per cent. It was, therefore, important to maintain the power factor at a point as close as possible to 70 per cent, if higher values proved unattainable. This test, and the curve showing its results, indicated the advantage of operating the furnace at an arc voltage as high as possible with relation to the supply voltage. At higher arc voltages the arc became unstable and could not be held.

The nature of the charge, under the conditions just mentioned, also has an appreciable influence on the stability of the arc, and hence on the power factor. This applies somewhat to the physical nature of the charge, but more particularly to its composition. The presence of any constituent which tends to stabilize the arc makes possible a higher arc voltage and more favorable power factor; the reverse is equally true. Some metals—zinc, for example—have a depressing effect on the arc

FIG. 1. ARC VOLTAGE AND POWER FACTOR

and, if present in considerable quantity, prevent the maintenance of a high-voltage arc. Certain slagging materials, on the other hand, have a stabilizing influence and improve the power factor. In one case it was found that the concentrates from the foundry recovery plant had a very marked and favorable influence when they formed a considerable percentage of the charge. The various kinds of materials normally making up the furnace charge in the plant, and their effects on the arc, will govern the practice to be followed.

The relative steadiness of load can be determined, imperfectly by observation, more satisfactorily by the use

of a recording wattmeter in the supply circuit. This point is of no great importance to the furnace user, except in its effect upon the attitude of the power supply company. The latter will usually be able to learn from charts taken in its station or substation whether the furnace load is exercising a seriously detrimental influence on its power line. If the power fluctuations are so violent, relative to the capacity of the line, that other customers of the company who take power from the same line are inconvenienced, it is necessary either to transfer the furnace load to a line of higher capacity or to isolate it entirely by building a separate line for its exclusive use. In the case of 2-phase or 3-phase furnaces, unbalancing of the phases may be a serious factor, which, unless it can be overcome by the furnace user, must be remedied by isolation or by the use of compensating equipment.

Resistance and induction furnaces are, as a rule, fairly free from violent fluctuations, and do not tend to unbalance the phases unless they are single-phase furnaces, in which case the unbalancing effect can be definitely predicted.

ADEQUACY OF ELECTRICAL EQUIPMENT

The adequacy of the electrical equipment which supplies the furnace must be learned by observation throughout the series of tests. The furnace transformer and the leads connecting it with the furnace have undoubtedly been chosen to take care of the expected power input at the expected power factor, with an ample margin of safety. If, however, the power input is unexpectedly high, or the power factor not so favorable as had been supposed, the transformer may be dangerously overloaded. The difference in temperature between the transformer oil and the surrounding air, taken when the furnace has been drawing its maximum load for some time, will indicate whether the transformer is likely to overheat seriously at any time, during a hot summer day, for example.

Low power factor may, in some cases, be caused by improperly designed or poorly placed leads, a condition which can be promptly detected and rectified. This subject has been thoroughly discussed by Lindstrom¹ and by Meyer.²

Metallurgical Characteristics

The metallurgical characteristics include the loss of metal during the melting operation, the quality of the metal with respect to the uniformity of its composition and the absence of undesirable impurities, the ease with which a specified composition can be produced, and the uniformity of temperature at which the metal is delivered from the furnace. It is upon these features of its performance that the superiority of the electric furnace commonly depends, and they must be determined with great care. With respect to all of these points it is desirable to get an exact comparison between the electric furnace under test and other furnaces operating on the same kind of work under similar conditions.

METAL LOSS

The weight of metal lost during the melting process has a direct bearing upon the cost of operation, whether the metal is irrevocably lost or can be partially recovered from slags, ashes, sweepings, etc. The object

¹A. Lindstrom: "Leads for Electric Furnaces," *MET & CHEM. ENG.*, vol. 16, p. 623 (1917).

²A. A. Meyer: "Electrical Characteristics of Electric Furnaces," *Trans., Am. Electrochem. Soc.*, vol. 31, p. 269 (1917).

of the melting process is to supply useful metal in the ladle or crucible, ready for pouring into castings or ingot. Metal not delivered to the ladle, but which can, nevertheless, be recovered, must obviously be remelted before it becomes useful, and such recovered metal can be credited to the furnace only at its premelted value, after due allowance has been made for the cost of recovery. The gross loss, by which is meant the difference in weight between metal charged and useful metal in the ladle, may sometimes be a more important factor than the net loss, or the discrepancy between metal charged and total metal delivered useful plus recoverable. A furnace showing a gross loss of 3 per cent, with a net loss of 2 per cent, is likely to be more economical than another which operates at a gross loss of 10 per cent and a net loss of only 1 per cent. On the other hand, if the net loss is low, a high gross loss is commonly due to carelessness, and this possibility must be considered in judging the furnace.

Two general methods are in use for determining metal loss, the choice of which depends upon the nature of metal melted, and also upon the object to be attained. The method of direct weighings must be used when handling a single metal, and is commonly to be preferred in the case of an alloy which contains a considerable percentage of a volatile metal. This includes copper and all of its alloys. Determination of metal loss by chemical analysis applies more particularly to the case of an alloy whose predominant constituent is non-volatile, and which contains small quantities of volatile metals. Many alloy steels fall in this class. The method may also be applied to certain ferro-alloys.

LOSS BY DIRECT WEIGHING

The method of direct weighings may be applied in either of two ways. The most accurate determination of net loss, in the case of copper and its alloys, can be made by pouring the molten metal into ingot molds at the furnace, taking great care to avoid spilling. The furnace is then scraped as clean as possible and these scrapings, together with the slag and spillings, are put through a hand recovery process. The difference between weight of metal charged and weight of ingots is the gross loss for that individual heat. The weight of metal recovered, added to the weight of ingots, is then subtracted from the weight charged, to determine the net loss. Instead of pouring the metal into ingots, the molten metal may be weighed in the ladle. This, however, involves some sacrifice of accuracy and is not to be recommended. Whenever it is worth while to learn the metal loss for individual heats, scrupulous care is justified in making the determination. The metal loss for individual heats becomes of importance when it is desired to learn, within the limits of a short test, the effect of different rates of power input, different pouring temperatures and other variations in operating conditions upon metal loss.

If uniform operating conditions are to be maintained, and it is desired to learn what the average melting loss will be under these conditions, separate determinations for individual heats are not necessary. Under these circumstances it is permissible to weigh the molten metal in ladles, and it is not necessary to scrape the furnace clean or ever to pour out the entire melt. The slag and spillings from individual heats need not be kept separate, but should be stored apart from similar accumulations of other furnaces. At the end of a series of heats—preferably ten or more—the furnace should

be entirely emptied and cleaned. The accumulated slag and spillings are then weighed and the recoverable metallic content determined. This may be done by hand recovery of a carefully selected sample, or by putting the whole lot through a recovery plant, if such is available. By this method good average results can be obtained, sufficiently accurate to indicate the performance of the furnace in this particular.

In determining metal loss by direct weighings three precautions must be observed. In the first place, the metal charged is often far from clean and, in the case of oily or wet borings, may not be more than 95 per cent metallic. Scrap castings, sprues and gates sometimes introduce a considerable quantity of sand. These non-metallic constituents of the charge may be responsible for a considerable error unless proper allowance is made for them. In case an appreciable weight of metal is added to the melt in the ladle, the addition should be credited as metal melted by the furnace. This correction will reduce the calculated loss somewhat, and plays an even more important part when the consumption of electric energy per ton of metal melted is considered. Metal loss determinations must never be made with a newly lined furnace, since, during the first two or three heats in a fresh lining, metal will seep into the cracks and pores of the refractory; as a result the net metal loss will appear to be about double the normal value.

LOSS BY CHEMICAL ANALYSIS

The chemical analysis method for determining metal loss is based on the assumption that at least one constituent, which must form a considerable percentage of the charge, is not subject to selective loss; that is, it neither vaporizes nor oxidizes during the melting operation. Any loss of this constituent which may occur is supposed to be due to spilling or spattering, in which case all constituents of the melt are lost in the same relative proportion, and the analysis of the alloy is unchanged. The composition of the charge is known or determined by analysis, and a sample of the metal poured is analyzed. The difference between these analyses is assumed to be due to volatilization or oxidation of constituents other than the one considered stable.

Suppose that we have an alloy which consists of two metals, A and B, and that the analyses, before and after melting, are as follows:

Metal	Before Melting, per Cent.	After Melting, per Cent
A.....	75.0	76.5
B.....	25.0	23.5
	100.0	100.0

If we consider that A has suffered no loss—except, possibly, by spilling—we can calculate as follows:

Let relative weight of A before melting	= 100.0
Then relative weight of B before melting	= 33.3
And relative weight of alloy before melting	= 133.3
According to assumption:	
Relative weight of A after melting	= 100.0
According to analysis:	
Relative weight of B after melting	= 30.7
Then relative weight of alloy after melting	= 130.7
Relative loss of alloy = $133.3 - 130.7 = 2.6$	
Percentage loss of alloy = $2.6 \div 133.3 = 1.95$	

We conclude, then, that for every 100 lb. of alloy melted we are losing 1.95 lb. of metal, which we assume consists wholly of B, and evaluate our loss accordingly. This, of course, is a net loss, since we cannot very well determine the weight of our spillings by chemical analysis. In respect to determining the gross loss, this method, even at its best, is deficient.

But suppose that there is, after all, a slight loss of metal A, by volatilization or oxidation, much smaller

than the loss suffered by B, but still appreciable. Let us say that this loss of A amounts to 0.25 per cent of its original weight. By recalculation we find that, on this basis, our net loss is 2.20 per cent, of which 0.19 per cent is A and 2.01 per cent is B. On a large tonnage basis, this difference between 1.95 per cent and 2.20 per cent would be an important item.

The method of chemical analysis has often been used to calculate zinc losses in the melting of brass and, in doing so, it is always assumed that the relative amount of copper in the alloy remains constant. This is not a correct assumption. There is almost invariably some oxidation of copper, and, in some cases, volatilization as well, with the result that losses calculated in this way are always too low. When we consider the added fact that a slight error in chemical analysis, or a slight lack of uniformity in the alloy as sampled, results in a disproportionately large inaccuracy in the result, it will be seen that this method, by itself, is not suitable for use with copper alloys. It is often valuable, however, if used in conjunction with the method of direct weighings. After the net loss of the alloy as a whole has been learned from the weights taken, the proportionate loss of the constituent metals can be determined by chemical analysis. This is of especial value in case the alloy contains three constituents, two of which are subject to considerable loss. If the three metals differ widely in market value, it is important to learn the proportionate loss of each, in order that the total loss may be correctly evaluated.

In the case of alloy steels, where the alloying constituent is exceedingly valuable, usually added in small quantities, and often subject in marked degree to volatilization and oxidation, determination of loss by direct weighings is of little value. Relatively speaking it is safe to assume that the proportion of iron is stable, and the chemical analysis method can most advantageously be used.

TEMPERATURE OF METAL IMPORTANT

Whatever method is used in determining metal loss, it is of great importance to know the temperature at which metal is delivered from the furnace during the test, particularly in the case of copper alloys. According to Gillett³, yellow brass (67 per cent copper, 33 per cent zinc) boils at approximately 1120 deg. C. (2048 deg. F.), while the correct pouring temperature for this alloy, if it is to be used in thin castings, is about 1075 deg. C. (1967 deg. F.). This leaves a margin of only 45 deg. C. between the desired pouring temperature and the boiling point of the alloy, at which latter point zinc will be volatilized at a high rate. It is obvious that no reliable comparison can be made between two heats, one of which is poured at, say, 1120 deg. C. (2048 deg. F.) and the other at 1050 deg. C. (1922 deg. F.), unless the difference in temperature is known and its effect discounted. In fact, metal loss figures, not accompanied by a statement of the temperature at which they are taken, lose much of their value and may become a source of serious misunderstanding. Determination of molten metal temperatures, by the best available means, is of the greatest importance, especially during a short test which is expected to furnish data from which estimates of economy can be made.

The quality of metal from the electric furnace should be carefully compared with that obtained from other

sources, since superiority in this respect is often the determining factor in the success of electric furnace operation. The basic qualities to be considered are homogeneity of composition and structure, and the absence of undesirable impurities. Upon these depend strength, the percentage of satisfactory castings, and other mechanical and physical properties which have a direct bearing upon the value of the product.

The structure of the metal may be superficially determined by examination of fractures. In some cases this point may be of sufficient importance to warrant a thorough metallographical examination. The presence of impurities and their percentages may be determined by the usual methods of chemical analysis and microscopic examination.

If the strength of the finished casting is of any importance under the conditions to which it is to be subjected in use, suitable tests should be made to determine its strength properties, as compared with castings from metal melted in other furnaces. These tests should, of course, take the form necessary to show what the performance of the casting will be under service conditions, depending upon whether it is to withstand hydraulic pressure, air pressure, steam pressure, tensile or compressive stresses, etc. It is sometimes found that the casting made from electrically melted metal is of appreciably greater strength than castings otherwise produced. This may justify a higher sale price for the casting, or it may make possible the use of a lightweight casting with strength equal to that of heavier castings previously used. In either case the additional profit, or the saving, should be properly accredited to the electric furnace.

DEFECTIVE CASTINGS

Defective castings are a constant source of loss which the foundryman struggles in vain to eliminate, and finally compromises by achieving what he concludes to be an irreducible minimum. This trouble is commonly due to a variety of causes, some of which are not in any way related to the condition of the molten metal as it leaves the furnace. Others, however, can be ascribed to the quality and physical state of the metal, and these can sometimes be almost eliminated by electric melting. So far as practicable, castings from the electric furnace should be separately inspected during the progress of the acceptance test, in order that the percentage of acceptable castings may be compared with similar figures from other furnaces.

In some cases the electrical conductivity of the product is of importance. Tests should be made to determine whether or not the metal from the electric furnace is inherently superior in this respect, and whether the methods commonly used to produce high electrical conductivity can be more easily applied and exactly controlled in the electric than in other furnaces.

In certain instances it has been found that electric steel castings lend themselves unusually well to heat treatment, with the result that the treated castings are of more uniformly high quality than castings from metal melted in other furnaces and subjected to the same heat treatment. Tests should be made to determine the presence of this quality, since it may be a source of saving or of additional profit.

The attainment of a specified metallic composition, within narrow limits, is sometimes an essential in the production of ingot metal or of castings for special purposes. The degree of ease and exactness with which

³H. W. Gillett: "Brass-Furnace Practice in the United States," U. S. Bureau of Mines Bull. No. 73, page 129 (1914).

this can be done in the electric furnace, as compared with other furnaces, should be determined in such cases.

The uniformity of temperature at which metal is delivered from the furnace is important in many ways. When once the correct pouring temperature for an alloy to be used on certain work has been learned, the strictest possible adherence to that temperature will prevent lost heats, save time, result in economy of heat units, minimize metal losses, and make for uniformity in the metal itself. The ease with which the electric furnace under test lends itself to temperature control is a factor to be considered.

In the refining of steel it is sometimes worth while to give separate consideration to the performance of the electric furnace as a melting furnace and as a refining furnace. It may function admirably for one purpose and be almost worthless for the other. Again, its reliability may be high when merely dead melting in an acid lining, while an attempt to carry out a refining process, in a basic lining, may result in a prompt destruction of the refractories. It is unsafe to conclude from a satisfactory performance under one set of conditions that the furnace will be equally successful under a quite different set of conditions. Each point must be considered with reference to the work which the furnace is expected to do, and the cost of removing phosphorus and sulphur, as well as that of carburization, may well be treated as distinct from the cost of melting.

Cost of Operation

The cost of operation is made up of the cost of electric energy used per ton of metal produced, the cost of slagging materials, etc., the cost of labor, the cost of operating auxiliary equipment, such as tilting, electrode-adjusting and water cooling devices, and the expense for carbon, graphite and similar parts which are regularly consumed as a part of the furnace operation.

The cost of electric energy depends upon the thermal efficiency of the furnace and upon those of its electrical characteristics which tend to govern the rate at which electric power is sold. The influence of the power input, the power factor and the steadiness of load have already been discussed. The exact estimation of these factors must be based on local conditions and on the stipulations imposed by the company which is to supply power for the furnace.

ENERGY CONSUMPTION

The quantity of electric energy required by the furnace per ton of metal melted can be stated in various ways, and the published statements concerning this requirement are sometimes very misleading. In one sense the significant value is the number of kilowatt-hours consumed per ton of molten metal delivered in the ladle. This is the economic figure upon which estimates of production cost must be based, but it is contingent, not merely upon the efficiency of the furnace, but also upon the weight of non-metallic material in the charge—which must be evaporated, melted or at least heated to incandescence—and upon the weight of metal volatilized, oxidized, absorbed by the furnace lining, skimmed off with the slag or spilled before it reaches the ladle. From the standpoint of determining the furnace efficiency it is better to base the kilowatt-hour consumption upon the weight of metal charged, thus eliminating the other factors mentioned which have nothing to do with this quality of the furnace. Any statement of energy consumption should be accompanied by information as to the sort

of metal charged, whether it is in the form of borings, recovery plant concentrates, light scrap, heavy scrap, ingot or a mixture of these, and whether it carries with it an appreciable quantity of non-metallic material. The state of the metal in these respects plays an important part in determining energy consumption. The approximate temperature at which the metal is poured should also be stated.

In the case of steel any figure given for kilowatt-hour consumption is practically worthless unless all metallurgical conditions are known, whether the process consists of dead melting cold scrap, melting and refining cold scrap or refining a molten charge. In the process of dead melting the energy consumption will be largely influenced by the percentage of iron oxide, or rust, included in the charge. In refining, the percentage of phosphorus and sulphur in the charge, as compared with their percentage in the finished product, plays an important part. The percentage of carbon in the finished steel must also be considered.

During the acceptance test this question of energy consumption must be dealt with from two standpoints. First, what is the inherent thermal efficiency of the furnace, at the required temperature, independent of metallurgical considerations? The final decision as to the heat economy of the furnace, and modifications of design or of operating methods calculated to improve such economy, depend upon an accurate determination of this point. Second, how many kilowatt-hours, per ton of metal produced, will be used by the furnace, in its present form and under the conditions imposed upon it by plant requirements? An adequate answer to this question is required in order that a correct estimate of production cost may be made.

HEAT BALANCE

The inherent thermal efficiency of the furnace is found by making a heat-balance determination. The heat generated in an electric furnace is disposed of in four ways: (1) A portion of the heat is dissipated from the walls and other parts of the furnace by radiation and by convection, (2) another portion is carried away in the water used to cool electrode holders, roof rings, etc., (3) a third portion is lost in the hot gases which escape through the electrode openings, open doors and crevices in the furnace structure, (4) the final and useful portion is absorbed by the metal in raising its temperature to the melting point, melting it and superheating it to the required pouring temperature. If a water-cooling system is not used this source of loss is, of course, eliminated. In determining the heat balance it is usual to make an estimate, based on theoretical considerations, of the heat absorbed by the metal—the pouring temperature of which must be known—measure the heat lost in the cooling water, approximately measure the radiation losses and evaluate other losses by difference. The ratio of heat absorbed by the metal to total heat input is the thermal efficiency of the furnace under the particular conditions existing when measurements are made.

When an electric furnace is started from the cold its walls absorb heat rapidly and radiate it very slowly. As time goes on this heat absorption decreases, radiation losses increase, and the furnace finally reaches an equilibrium at a temperature which depends upon the rate of power input and upon the nature of the metal being melted. Up to this point, the thermal efficiency, starting at a low value, has been increasing, and it reaches its maximum at the equilibrium temperature. The furnace

walls may now be said to be saturated, i.e., they contain all of the heat they are capable of holding at the equilibrium temperature. So long as the equilibrium is maintained, the quality of heat held by the walls remains constant, and the rate of radiation loss from the outer walls exactly equals the rate of heat absorption by the inner walls. If the power input is sensibly decreased, the inner walls feed heat back to the metal in the furnace, the equilibrium temperature drops and the radiation losses decrease. During this time the thermal efficiency will apparently be abnormally high, perhaps even higher than 100 per cent, but this apparent value is a false one, since the metal is really receiving part of its heat from heat energy previously stored in the furnace walls. This heat energy must be restored to the walls before the former equilibrium temperature can be regained and a normal rate of melting at a normal efficiency once more attained. If the furnace is allowed to stand inactive the stored heat is lost by radiation from the walls, at a rate which decreases more and more gradually. If the furnace is restarted before the stored heat is altogether gone the remaining portion serves a useful purpose as a foundation upon which to build in restoring the temperature of the furnace to its normal operating value.

DETERMINING LOSS OF HEAT DURING NIGHT

When an electric furnace is operated during the day only, the loss, during the night, of heat energy which has been stored in the furnace walls during the day may become a very serious matter, especially in the case of a heavily-lagged resistance furnace. In testing such a furnace it is worth while to determine, as accurately as possible, what is the absorption capacity of the walls and how much residual heat is still left after the furnace has stood idle for several hours. An exact determination of these values is laborious and inconvenient; an approximate determination, which is at the same time sufficiently accurate, can be made more easily.

For this purpose, a test should be made, starting from the cold, with the furnace empty. The power input should be high enough to heat the furnace about as rapidly as would be the case in actual practice, and the temperature of the furnace chamber should be measured at frequent intervals, by means of a pyrometer. A base metal couple may be used for the lower ranges, but above 1300 deg. C. it is necessary to employ a radiation or optical pyrometer, or some other form of instrument more suited to the higher range. When the furnace has reached its maximum operating temperature the power input should be reduced until it is just sufficient to maintain the temperature at the desired point. This power input—the exact value of which should be determined as closely as possible—is, then, equivalent to the rate of heat loss, expressed in kilowatts, by wall radiation, cooling water, and other sources, at that particular temperature. The power should now be turned off and the furnace allowed to cool, with temperature readings taken at frequent intervals as before.

A cooling curve, drawn from these data, showing furnace temperature plotted against time, may be used to determine rate of heat loss at any given temperature during cooling, and also the quantity of heat still stored in the walls. Such a curve is shown in Fig. 2, illustrating a temperature drop from 1500 deg. C. to 450 deg. C. in 14 hours. In this case the power input required to maintain a temperature of 1500 deg. C. after the furnace had reached an equilibrium at that temperature was 40

kw. At any given moment the rate at which heat is being lost is proportional to the slope of the cooling curve at that point. Knowing this loss to be 40 kw. at the instant power was shut off, the rate of loss at any other point may be determined graphically by the use of the triangles shown, each having a base which represents one hour's cooling, and an altitude which is proportional to the instantaneous rate of cooling at the beginning of the hour.

For example, the rate of cooling at the beginning of the second hour is to the rate of cooling at the beginning of the first hour as b is to a . We already know

FIG. 2. COOLING RATE OF RESISTANCE FURNACE

that a corresponds to 40 kw., and we find by measurement that $b:a::15:24$. Thus we have $b:40::15:24$; $b = 25$ kw., the instantaneous cooling rate at the beginning of the second hour. The lower curve in Fig. 2 shows the rate of cooling throughout the 14-hr. period, determined in this manner for each hour.

It cannot be claimed, of course, that this method gives absolute accuracy, but it does give approximate accuracy in a manner which is at once simple and useful. The cooling curve is exponential and has an equation which is complicated and does not lend itself to rapid calculation. As given, it includes not only the radiation losses, but also the losses by convection of heated air currents, losses in the cooling water—if this is used and continues to flow after the power has been shut off—and losses by direct conduction where the furnace comes in contact with its supports. In determining the thermal characteristics of a furnace it is of great advantage to group these losses under a single head and thus be able to calculate their net effect. To be strictly correct, one must use as ordinates in such a diagram as shown in Fig. 2, not the actual furnace temperature as measured, but the difference between this temperature and the temperature of the air surrounding the furnace. If cooling water is used, the fact that its temperature is probably lower than room temperature introduces an additional complication, for which correction can be made if desired. In practice these refinements are troublesome and by no means essential, so long as one is dealing with temperatures not lower than 400 or 500 deg. C.

In a furnace which is cooling from a temperature at

which it was in a state of equilibrium—that is, saturated with as much heat energy as it would hold at that temperature—it is approximately correct to say that the heat content of the furnace, at any time, expressed in kilowatt-hours, is directly proportional to the temperature of the furnace chamber. This is not strictly correct, because the specific heats of the various materials of which the furnace is built are not constant at all temperatures, but experience has shown that the assumption is sufficiently exact for the purpose we have in mind. We can now determine the heat content of the furnace by assuming, first, that the average rate of loss during any hour is the mean of the rates of loss at the beginning and at the end of the hour, and, second, that the total heat loss between any two furnace temperatures is proportional to the difference between those temperatures. On this basis we find that our furnace has lost 32.5 kw.-hr. of stored heat during the first hour, 22.5 kw.-hr. during the second hour, and so on to a total of approximately 158 kw.-hr. during the whole 14-hr. period. During this time the furnace temperature has dropped from 1500 deg. C. to 450 deg. C., or 70 per

FIG. 3. THERMAL CHARACTERISTICS OF RESISTANCE FURNACE

cent, and therefore, according to our assumption, has lost 70 per cent of its stored heat. The total heat storage at 1500 deg. C was, then, $100 \div 70 \times 159$, or 226 kw.-hr., of which 68 kw.-hr. remained in the furnace at the end of 14 hours.

In Fig. 3 curves are given, based on these data, which show kilowatt-hours per hour loss, kilowatt-hours heat content of furnace, and hours required to cool to a given temperature, all plotted against furnace temperatures. These curves form a complete diagram of the net thermal characteristics of the furnace, upon which operating schedules may be based, and the correctness of furnace design for the particular work in question may be judged.

Fig. 4 shows an application of this method, in which, under conditions of 10-hr. operation, a test was made to determine the effect of residual heat energy at the beginning of the day, on the time required to complete the first heat, and on the thermal efficiency of the first heat. The higher values of residual energy were obtained by the application of a small power input during the night, the economic value of which in terms of production and operating efficiency could thus be determined without prolonged test.

Fig. 5 shows a diagram of one day's operation, in which the percentage of total energy input, as utilized and dissipated in various ways, is plotted against the total input expressed in kilowatt-hours. A represents the heat absorbed by the metal, calculated as 160 kw.-hr. per ton of brass at 1090 deg. C. (1994 deg. F.), B the various heat losses from the furnace during operation, and C the heat absorbed by the furnace structure as its temperature rises. In each of the rectangles shown in the diagram, the altitude indicates the percentage of

FIG. 4. RESIDUAL ENERGY-EFFICIENCY AND TIME, FIRST HEAT OF DAY

heat input disposed of in the manner indicated, while its area is proportional to the heat input in kilowatt-hours. In rectangles marked A the altitude represents also the thermal efficiency of the furnace during each heat. The shaded areas indicate the heat energy stored

FIG. 5. HEAT BALANCE OF RESISTANCE FURNACE

in the walls of the furnace, that marked "Residual" being the initial stored heat with which the furnace started the day. The figures show the numerical values of each area in kilowatt-hours. The broken-line curve indicates the rate at which heat is being stored by the furnace, or what is virtually the same thing—the rate of temperature rise.

It will be noted, in this diagram, that during the first two heats a relatively enormous amount of energy was

being stored by the furnace and its temperature increased rapidly. The third heat covered part of the lunch period, during which power was turned off. As a result the furnace temperature increased very little and the apparent efficiency was comparatively high. The efficiency dropped during the fourth heat as the rate of heat absorption by the furnace again increased. The maximum operating temperature of the furnace was not reached until the end of the fifth heat. During the sixth heat the furnace "coasted," that is, the power input was reduced to such an extent that the furnace temperature began to decline slowly, and the furnace walls gave up part of their stored energy to heat the metal and supply radiation losses, which is shown graphically by the fact that the rectangle *C* is above the 100 per cent line and really has a negative value. At the same time this coasting caused the apparent thermal efficiency to rise to a value somewhat higher than the true efficiency.

In the study of heavily lagged resistance furnaces, such curves and diagrams as these, based on data covering only a few days' operation, are of more value than weeks of operation unsupplemented by graphical interpretation. By the use of these methods the performance of the furnace under different conditions, as well as its merits and defects of design, can be evaluated with surprising accuracy, and desirable changes in design and operating methods can be made with a considerable degree of precision.

COOLING-WATER LOSS

In making a heat balance it is sometimes desirable to know what portion of the energy input is being carried away in the cooling water. This is determined by measuring the temperature of the incoming and of the outgoing water, and weighing the water used during a certain time period, or measuring the water by means of a water meter. Multiplying the weight of the water in pounds by its temperature rise in degrees F. gives its acquired heat content in B.t.u., and this may be converted into kilowatt-hours by dividing by 3416. The rate of heat loss in kilowatts may then be determined by dividing the heat gain in kilowatt-hours by the fraction of an hour during which the observed weight of water was used.

Several such determinations are necessary in order to get a good average value, and it is sometimes advisable to determine the rate of loss at different speeds of cooling-water flow, and to observe the general effect of this variation on furnace operation, in order that the use of cooling water may be so adjusted as to obtain the highest overall economy. The magnitude of this loss is frequently in the neighborhood of 10 per cent of the total power input, and, under favorable conditions, may be much higher.

While the heat-balance determination indicates the fundamental thermal characteristics of the furnace *per se*, the only way to learn what the energy consumption will be under practical conditions in any specified plant is by careful observation of the kilowatt-hours used from heat to heat. Since different heats are often subject to different conditions, it is important to note the energy consumption on each heat and to accompany these data with an adequate description of the conditions—such a description as given by the furnace log—in order that the effect of varying conditions may be learned. For this purpose, as already stated, it is necessary to use a watt-hour meter, the readings of which

may be estimated with fair accuracy to 1 kw.-hr. as a unit, unless the furnace is large, using, say, as much as 1000 kw.-hr. per heat—in which case readings taken in tens of kilowatt-hours are close enough.

During the preliminary test one should learn approximately what energy consumption is to be expected. The brief intensive test should furnish data to show the best results of which the furnace is capable, when operating under regular plant conditions but subject to very careful supervision. These figures may be used as a basic value with which to compare results obtained during the more extensive operating test, with supervision reduced to a practical minimum. The information thus obtained, together with the heat balance, is sufficiently comprehensive to justify complete estimates covering the effect of all conditions likely to be encountered, the relative economy of various operating schedules which may be proposed, the advisability of changes in design, and the influence of human factors such as skill of the operator, attitude of foremen and laborers in the plant, etc.

The energy consumption per ton of metal depends in marked degree upon the temperature to which the metal is heated by the furnace. Useful comparisons are impossible unless the approximate temperature of the metal is known. The importance of the pyrometer in electric-furnace testing has already been emphasized, and, in connection with determinations of energy consumption, can hardly be overemphasized.

MATERIALS AND LABOR

The cost of raw materials includes fluxes and slagging materials, and the cost of the metal charged. Fluxes, etc., constitute a relatively small item, but one which, nevertheless, should be recognized and included in the balance sheet. The cost of metal charged is a production rather than an operating cost, but, under certain conditions, should be included under operating costs as a differential when comparisons are to be made with other types of furnaces. For example, if it is found that the electric furnace requires a less expensive grade of metal than is used by some other furnace, in order to turn out the same quality of product, the difference in cost should be credited to electric-furnace operation. Or if, as sometimes happens, the electric furnace can utilize as part of its charge badly oxidized or otherwise impure material which would otherwise have to be sold at a loss, this saving should be credited in a similar manner. Of course, if the reverse is true, the differential consists of a charge against the electric furnace instead of a credit.

Throughout the acceptance test the labor required to operate the electric furnace should be carefully observed, in order that the labor necessary, not merely as to quantity but also with respect to quality, may be accurately estimated when the test has been completed. The comparison between the intensive test and the operating test, the latter with reduced supervision, will indicate how expensive a grade of labor is justified on economic grounds.

Auxiliary equipment, such as tilting motors and electrode-regulating apparatus, must ordinarily receive their power supply from a separate circuit, since the characteristics of the furnace circuit are usually unfavorable to their operation. Their use of electric energy may be estimated, if desired, but is so small as compared with that used by the furnace that the cost of energy consumed in this way is not an important factor. The cost

of water used in cooling electrode holders or other parts of the furnace equipment may under some conditions deserve a place in the table of costs, although it is, of course, small.

The cost of carbon, graphite or other materials of a similar nature, which are employed in electrodes or resistor parts, is an operating cost, provided these materials are regularly consumed during operation. Such materials as are relatively long-lived, and replaced at irregular intervals, are more properly considered under the head of maintenance cost.

Carbon and graphite parts are usually purchased by the pound, and the weight consumed per ton of metal produced should be determined. In the case of electrodes for arc furnaces, where breakage is an important factor, it is worth while to differentiate between electrode consumption and electrode breakage. This can be done by weighing the broken pieces of electrode, from time to time, as they accumulate, and comparing this weight with the total weight of electrodes used during the same period. Electrode breakage is, theoretically, an avoidable waste and a good deal of time and effort can profitably be spent in reducing it to a minimum. Any pronounced discrepancy between electrode consumption, as determined during the intensive test, and that found in practice during the operating test should be thoroughly investigated.

Maintenance Cost

The cost of maintenance includes the expense involved in renewing the refractory parts of the furnace from time to time, and in making such repairs as may be necessary on the furnace and its auxiliary equipment. The necessary observations include the nature and weight of materials used and the quantity and quality of labor required, all to be reduced to a basis of cost per ton of metal output. If the renewals and repairs involve serious interruptions of operation, special consideration must be given them under the head of reliability and production.

The cost of refractories is difficult to determine in a test of short duration. If the furnace is well designed, and well suited to its purpose, its refractory parts will not need very many or very extensive renewals during the course of a two-months test, and it is not easy to estimate from the results of such a test what the cost of refractories will be over a period of, say, one year. The best estimate which can be made must be based on close observation of the condition of the roof and lining at frequent intervals. In the case of an arc furnace the roof may have to be replaced one or more times, particularly if the furnace is operated continuously, and the cost of renewal should be carefully noted. In an induction furnace the lining will be subject to much more rapid wear than the roof, and the effect of alternate heating and cooling, if the furnace is not run continuously, should be carefully noted.

CONSIDERATION FOR SAVING IN MATERIALS

In making cost estimates with respect to refractories, due consideration should be given to the possibility of using less expensive or more durable materials, which may happen to be well suited to the work in question. For example, it has been found that in melting certain classes of copper alloys in an arc furnace, roofs constructed of ordinary firebrick are not only cheaper in first cost than those of silica brick, but are also more durable.

Miscellaneous Considerations

There are a variety of miscellaneous factors, not so far considered, which play either a direct or an indirect part in determining the cost of production or the overhead expense of the plant. Taxes and interest charges on the investment, the loss involved in disposing of equipment already in use, depreciation and obsolescence charges against the electric furnace equipment, make up one group which affects production cost directly. If the electric furnace makes possible a saving in floor space which is really needed for other purposes, or if it reduces the insurance rate for the plant, these are also items which can be evaluated with a fair degree of exactness.

Depreciation and obsolescence charges lend themselves excellently well to what may be termed scientific juggling resulting in almost any conclusion which the juggler may wish to reach. A few general principles should be observed in making such estimates. In the first place, the transformers, foundations, furnace leads, instruments, etc., should always be included with the furnace. As a rule these items are specially designed for use with the particular furnace in question, and are of much less value for any other purpose. Their depreciation should be calculated at the same rate as that of the furnace.

No well established rule will be found for calculating electric-furnace depreciation. The proper rate to use will vary with circumstances. The writer has in mind one installation, just going in, where a depreciation rate of not more than 5 per cent per annum might well be used. In applications where a well standardized furnace has long been used in other plants for the same purpose, 10 per cent is a conservative value. This applies particularly to certain well known furnaces widely used for melting and refining steel. In other cases, where the application is a relatively new one and the electric furnaces now in use are pioneers, obsolescence becomes the governing factor and 20 per cent is a safer value. There are some installations, established solely as a result of the abnormal conditions existing during the war, which lost about 90 per cent of their value on the day the armistice was signed.

The advantages of greater cleanliness and less noise, which often favor the electric furnace, as well as that of greatly reduced radiation of heat, which always accompanies electric-furnace operation, are of such a nature that they cannot be exactly evaluated. The net effect of such indirect advantages is very different in different locations, depends largely upon the type of fuel-fired furnace with which the electric furnace is being compared, and, in its influence on working conditions and other considerations, both economic and æsthetic, its importance will depend upon the climate, the class of labor employed, the location of the plant with respect to residence sections and other buildings, public or private, and finally, on the attitude of the plant management in dealing with considerations which have to do principally with the welfare of employees and questions of public interest. The question of poisonous and unpleasant fumes and gases given off during the melting operation has a similar bearing on the subject. In this connection the degree of ventilation which already exists in the plant, or may easily be attained, must also be considered.

Up to this point we have considered separately the individual features of electric-furnace performance, the

bearing which each has upon the performance as a whole, and methods for obtaining adequate and reliable data with respect to these factors during the progress of an acceptance test, made in an industrial plant under commercial conditions. When the test has been completed and the desired information is all in hand, there still remains the task of summarizing the results, scrutinizing each detail in the light of its influence on the final result and giving to each its proper weight, totaling the costs and estimating what these will be under such variety of conditions as are likely to be met with in the plant concerned, comparing these costs with corresponding figures obtained from other sources, and, finally, giving judgment as to the overall value of the furnace for use in the plant in which it has been tested. The correctness of the conclusions reached will depend no less on the use of good sense and engineering judgment in interpreting results than on the skill and care with which the test has been made.

Questions to Be Answered

The engineer charged with the task of judging the quality of performance which the furnace has shown must, after a careful study of the data, arrive at the correct answers for the questions given below, preferably to be considered in the order given. Not all of these questions need be considered in every case. Which of them are pertinent depends upon the nature of the furnace tested and upon the requirements of the plant in which its use is proposed.

A. SUITABILITY

Is the furnace suitable, in a general way, for the work which it is expected to do? Will it produce a marketable product from suitable raw materials without any gross failure to meet the requirements of the industry in other respects? If it is lacking in this regard, is its failure due to some fault inherent in its design, or can its performance be rectified by minor changes in construction or operating methods?

B. RELIABILITY

Is the furnace sufficiently reliable in its operation to be classed as an industrial tool? If its apparent reliability leaves something to be desired, what part of the trouble should be ascribed to the furnace itself and what to imperfections in its auxiliary equipment or other contributing causes? Can the difficulty be overcome in any practical way?

C. PRODUCTION

What rate of production can the furnace be expected to show under the conditions normally existing in the plant? Can this rate be increased, under existing conditions, by changes in furnace design or operating methods? What rate of production is the furnace capable of, if conditions are modified to meet its requirements? Does the increased production thus made possible seem to justify the necessary modifications?

D. NATURE OF METAL HANDLED

Is the furnace capable of handling in a satisfactory manner all of the various forms of metal which it is desired to use in this plant? Is it more or less satisfactory than other furnaces in this respect?

E. ELECTRICAL CHARACTERISTICS

1. *Power Input.* What is the average power input of the furnace under the various conditions of its use? Is it, for any reason, desirable to raise or lower this input, and, if so, how readily can this be done?

2. *Power Factor.* What is the average power factor of the furnace? Is it so low as to subject the furnace load to a penalty which will affect the rate paid for electric energy? If there is danger of this, how can the power factor be maintained at the highest practicable value?

3. *Steadiness of Load.* Is the power input subject to violent fluctuations which may be dangerous to the transformers or objectionable to the power company? If so, how can this condition best be remedied?

4. *Adequacy of Electrical Equipment.* Are the transformers, leads and other electrical equipment suitably

designed and connected for use with the furnace? If not, what changes should be made?

5. *Rates for Electric Power.* With the electrical characteristics of the furnace as they are, and at the estimated use of power, what will be the average cost per unit of electric energy used? Can this cost be reduced?

Are the electrical characteristics of the furnace such that it constitutes an undesirable load for the local power company or for the power system of the plant? How readily, if at all, can undesirable characteristics be improved? Are conditions such that it will be necessary to install additional equipment in order to compensate for undesirable characteristics? If so, how can this best be done and what will it cost to install and operate such equipment?

F. METALLURGICAL CHARACTERISTICS

1. *Metal Loss.* What gross and net metal losses are experienced with the furnace under the conditions of its use? How does it compare with other furnaces in this respect? Can the results obtained during the test be improved upon? What is the value of the loss expressed in cost per ton of metal produced?

2. *Quality of Metal.* How does the quality of metal produced by the furnace compare with that from other furnaces, judging it according to the purposes for which the finished product is to be used? Is it likely that better results can be obtained? Does the furnace make possible a product which can be sold at a price above the average? Does it make direct savings in production as compared with other furnaces?

How do the metallurgical characteristics of the furnace compare with those of other furnaces used on similar work? Can the furnace be improved in this respect?

G. COST OF OPERATION AND MAINTENANCE

1. *Energy Consumption.* What energy consumption does the furnace show, per ton of metal produced, under the conditions of its use? In this respect, how does the furnace compare with other electric furnaces doing similar work? Is the furnace capable of giving better results?

2. *Thermal Efficiency.* What is the inherent thermal efficiency of the furnace? How well do its thermal characteristics conform to requirements imposed by the operating schedule of the plant? Can these characteristics be changed for the better? Would it be advantageous to modify the operating schedule?

3. *Cost of Carbon and Graphite Parts.* What is the cost, per ton of metal produced, for electrodes or other carbon and graphite parts? How much of this cost is necessary and how much due to avoidable waste? What seems to be the minimum practicable cost of this item? How does the furnace compare with other electric furnaces in this respect?

4. *Labor.* What is the labor cost per ton of metal produced? Can this item be reduced? Would it decrease if the installation were to be enlarged by the addition of more furnaces? How does this cost compare with that for other furnaces, electric or fuel-fired? What grade of labor should be employed to produce most economical results?

5. *Metal Charged.* Does the furnace show greater or less economy than other furnaces with respect to the grade of raw materials which it utilizes?

6. *Miscellaneous Materials.* What is the total cost, per ton of metal produced, for incidentals such as fluxes, slagging materials, water, etc.?

7. *Refractories.* What is the cost, per ton of metal produced, for renewing furnace refractories? How does the furnace compare in this respect with other electric furnaces? Can the overall economy be improved by substituting cheaper or more durable refractories for some of those now in use?

How does the overall cost of operation compare with that of other furnaces under similar conditions? Is it probable that this cost can be reduced?

H. OTHER CONSIDERATIONS

1. *Depreciation.* What rate should be charged for depreciation or obsolescence of the electric furnace installation? What does this amount to in cost per ton of metal produced, on a basis of the estimated production?

2. *Interest and Taxes.* What is the estimated cost, per ton of metal produced, for interest and taxes on the electric furnace investment?

3. *Miscellaneous Economic Considerations.* Does the furnace make possible a saving in plant insurance rates

as compared with other furnaces in use or under consideration? Does the furnace make possible a saving in floor space which is really needed for other purposes?

4. *Working Conditions.* Does the furnace possess advantages over other types of furnaces with respect to cleanliness, silence of operation, absence of excessive radiated heat, freedom from noxious gases and fumes, and the like, which have a bearing on the health and efficiency of the workmen, and, in general, on the hygienic condition of the plant and its surroundings? Of what importance are these advantages under the conditions which exist in and around the particular plant in question?

Summarizing these factors, does the furnace possess peculiar advantages, as compared with other furnaces, by virtue of its ability to utilize cheaper raw materials, or its ability to save materials otherwise unavoidably lost, or its ability to turn out a product of higher grade?

Exclusive of such of these advantages as it may possess, does the furnace show a higher or a lower operating cost than other furnaces?

Considering both special savings and operating costs, how does the overall economy of the furnace compare with that of other furnaces under consideration?

Does the furnace possess incidental qualities, not easily evaluated in dollars and cents, which have any bearing for or against its use?

Considering the overall economy of the furnace, together with such special and incidental advantages as it may possess or lack, does it seem advisable to choose this particular furnace as new equipment in preference to other furnaces which might be used?

What loss would be involved in selling, or consigning

to the scrap pile, other furnaces already in use in the plant, and replacing them with additional electric furnaces of the type under test? Is this action advisable?

If the present superiority of the electric furnace for use in this plant is based on abnormal conditions, what will be its status when these conditions no longer exist?

If the adoption of the electric furnace is not now advisable, is it likely to become so under changed circumstances which may be expected to arise in the future?

In answering these questions the engineer who is reporting the test will have covered very thoroughly all of the technical and economic factors which play a part in the success or failure of electric furnace installations in the field under discussion. The matter of general supervision and plant overhead is not included, as this question depends upon many factors which have little or nothing to do with the electric furnace, factors concerning which the engineer who is testing the furnace can hardly be expected to have complete information. In any case this item will be much the same for one furnace installation as for another, provided the rate of plant production is identical. The plant manager, if he has before him such a report as that indicated above, can reach a final decision concerning the furnace, which will be based on all the facts, accurately determined and adequately presented.

Detroit Electric Furnace Co.,
Detroit, Mich.

Industrial Analysis of Gas Mixtures by the Refractometric Method

THE June, 1919, issue of *Chimie et Industrie* contains a comprehensive description of the application of interference phenomena to the industrial analysis of gas mixtures, by Prof. Marcel Pouchon.¹ The following is an abstract of this interesting study.

The volumetric and gravimetric methods of gas analysis present disadvantages which are not encountered when using the method based on the variation of the index of refraction of gases. To obtain the index of refraction of a gas mixture it is necessary to know the index of each of the components. The refractometric method is applied easily when analyzing a binary mixture. For more complex mixtures this method does not offer any appreciable advantage over the standard volumetric and gravimetric methods.

The main difficulty encountered in the application of this method is the smallness of the value to be measured. Thus, the difference of the index of refraction between pure air and a mixture air-carbon dioxide (say 95 per cent air, 5 per cent carbon dioxide) is about 10^{-5} . To obtain results accurate to within ± 1 per cent, the readings have to be taken with an exactitude of 10^{-7} . This extreme sensibility is secured by the application of the phenomena of interference as obtained when using Lord Rayleigh's gas interferometer.²

LORD RAYLEIGH'S PORTABLE INTERFEROMETER

There are two types of gas interferometers, the laboratory type and the portable type. The portable type (Fig. 1), which is used industrially, is represented schematically in plan and elevation in Figs. 2 and 3.³

¹Prof. Marcel Pouchon, "Analyse industrielle des Mélanges Gazeux par la Méthode Réfractométrique," *Chimie et Industrie*, June, 1919, pp. 647-655.

²Lord Rayleigh, *Proc. Roy. Soc. (A)*, vol. 59, 1896, and vol. 64, 1898. F. Lowe, *Physik. Z.*, vol. 11, 1910.

³The laboratory type of Lord Rayleigh's gas interferometer is described by Frank M. Seibert and Walter C. Harpster in the U. S. Bureau of Mines Technical Paper No. 185, 1918.

It consists of (1) a vertical slit F_1F_2 , source of light s , lens l , mirror m and prism p ; (2) a lens L the focal plane of which contains the slit F_1F_2 ; (3) two glass plates C, C' of which the plate C' is movable around the horizontal axis aa ; (4) a glass parallelepiped P ; (5) a plane mirror M ; (6) two gas chambers G, G' closed at their parallel extremities with glass plates.

PRINCIPLE OF THE APPARATUS

At F_1 , the upper part of the slit, there are formed two pencils P_1 and P_1' which pass through the plates C, C' , the gas chambers G, G' , then are reflected by M back through the gas chambers G, G' , and plates C, C' , and form after passing through the lens L interference bands in F_1' .

At F_2 , the lower part of the slit, there are formed two pencils P_2 and P_2' which pass through the lens L

FIG. 1.

and are then deflected by P so as to sidestep the gas chambers G, G' and reflected by the mirror M back through P and L , when the pencils form bands in F_2' .

These two systems of bands are spaced one over the other and separated by a horizontal black band. The observations are made through a cylindrical lens O . The

central band only is achromatic, the others are colored and can be easily distinguished.

By turning the plate C' around the axis aa the path of the pencils P' and P'' can be varied and by this means displace laterally the upper system of bands. The two central bands can thus be aligned. Under these conditions the optical paths followed by the pencils P_1 and P'_1 are the same. The displacement given to C' is measured by the micrometer screw S (see Fig. 1).

METHOD OF OPERATION

To measure the difference of the index of refraction of two gases it is first necessary to start with filling the two gas chambers G and G' with a standard gas, and by manipulating the micrometer screw S , C' is brought to the position where the two central bands are in alignment, and the position of the micrometer is noted. This is the zero point. Now one of the gas chambers, say G' , is filled with the gas to be studied and the central bands are again aligned by means of S . The new position of C' is noted, and the displacement of the micrometer screw S measures the variation of the optical path of P' when the standard gas is replaced by the

FIG. 2

gas to be studied. This displacement is a function of the difference of the index of refraction of the two gases.

Every apparatus has to be standardized, by using as standard gas and as a gas to be studied gases whose indices of refraction are well known, such as carbon dioxide, ammonia, etc.

The displacements of the micrometric screws are proportional to the variation of the index, i.e., the readings plotted with the micrometer displacements as abscissæ and the difference of indices of refraction as ordinates give a straight line (see Fig. 4). This is the standardizing curve. The sensitiveness of the apparatus depends on the length of the gas chambers G , G' : The longer the chambers, the more sensitive the apparatus.

Although the apparatus once standardized can be considered as such indefinitely, it is better to restandardize it from time to time and check the standardizing curve.

ANALYSIS OF A GAS MIXTURE

A gas mixture is analyzed by comparing it to one of its constituents taken as standard gas, and the results are calculated by the application of the following laws:

(a) The refractivity of a gas is proportional to its absolute density.

$$\frac{N-1}{D} = \text{constant} \quad (1)$$

in which N is the absolute index of refraction of the gas and D the absolute density or mass per unit volume of the gas under given conditions of temperature and pressure.

(b) The refractivity of a gas mixture is equal to

the sum of the refractivities of each of the gases at the pressure they would have if they were to occupy individually the total volume.

$$N-1 = (N_1-1) + (N_2-1) + \dots \quad (2)$$

in which N is the absolute index of the mixture and $N_1, N_2, \dots$ the indices of the components at the pres-

FIG. 3

sure they would have if they were to occupy individually the total volume.

From these two formulæ it is found that for a binary mixture if N'_1 is the index of refraction of a pure compound initially filling the gas chamber G' , N'' the index of the mixture to be analyzed, p , the mass of one of the components contained in a unit volume of the gaseous mixture and d_1 its relative density (the other component being taken as the standard)

$$p_2 d_2 a \frac{N''-N'_1}{N_2-N_1} \quad (3)$$

when the gases filling the gas chambers G and G' are at the same temperature and pressure.

The weight of the constituent not taken as standard, contained in the unit volume of the mixture at the experimental temperature and pressure, is proportional to the difference between the index of refraction of the

FIG. 1

TABLE 1—VERIFICATION OF THE PROPORTIONALITY OF THE DISPLACEMENT OF THE MICROMETER SCREW TO THE WEIGHTS OF ONE OF THE CONSTITUENTS IN THE UNIT VOLUME OF THE MIXTURE

Gas Mixed with Air (1)	Composition of the Mixture to Be Studied (2)	Displacement of the Micrometer Screw (3)	Value (2) Value (3) (4)
	Grains per cu. m.	Divisions	
Carbon dioxide	49.0	96	0.516
	313.0	613	0.518
	585.0	1140	0.513
	1230.0	2410	0.510
Ethyl alcohol	67.5	436	0.114
	87.0	565	0.134
	100.0	63	0.137
	114.0	721	0.133

FIG. 5

mixture and that of the constituent taken as standard, i.e., to the displacement of the micrometer screw.

This proportionality is easily verified experimentally. Thus, taking pure air as the standard gas and as the gas to be studied, the mixtures air-carbon dioxide, air-alcohol, etc., the results shown in Table I were obtained.

PRECISION OF THE RESULTS

In the value $p_2 = d_2 a \frac{N'' - N_1'}{N_2 - N_1}$ errors can be made on the factors $N'' - N_1'$, $N_2 - N_1$, d_2 and a . The errors on d_2 and a are practically negligible. Experiments have shown that the error made when bringing the two central bands into alignment is not more than 1×10^{-7} in the index difference. The error in p_2 varies with the difference $N'' - N_1'$; $N_2 - N_1$ is known within a limited precision.

Table II gives examples of the precision reached with different gases mixed with air, assuming $N'' - N_1'$ known to $\pm 1 \times 10^{-7}$. Table III gives the indices of refraction of some gases.

TABLE II—PRECISION OF THE RESULTS OBTAINED IN THE ANALYSIS OF MIXTURES OF AIR WITH SOME GASES

Gas Mixed with Air	Error on p_2 , Grams per cu. m.	Gas Mixed with Air	Error on p_2 , Grams per cu. m.
Nitrogen.....	24	Acetone.....	0.3
Oxygen.....	5	Ordin. ether.....	0.3
Carbon monoxide.....	3	Ethyl alcohol.....	0.3
Water.....	2	Methane.....	0.5
Carbon dioxide.....	1		

TABLE III—INDICES OF REFRACTION OF SOME GASES

Gas	Index of Refraction	Gas	Index of Refraction
Air.....	1.0002926	Sulphur dioxide.....	1.000660
Nitrogen.....	1.0002978	Acetone.....	1.001079
Hydrogen.....	1.0001390	Benzene.....	1.001691
Oxygen.....	1.000272	Ordin. ether.....	1.001535
Ammonia.....	1.000377	Ethyl alcohol.....	1.000881
Carbon monoxide.....	1.000342	Methane.....	1.0004438
Carbon dioxide.....	1.0004502	Ethane.....	1.0007528
Water.....	1.000257	Pentane.....	1.001701
Chlorine.....	1.000769		

The absolute error in N_1 and N_2 is of the 10^{-6} order, but the difference $N_2 - N_1$ varies in appreciable pro-

portion. Thus it is 52×10^{-7} for nitrogen and air, 1576×10^{-7} for carbon dioxide and air, 12420×10^{-7} for ether and air, etc. It follows that:

In the analysis of a mixture in which the amount of one of the constituents is small, the precision of the results depends solely on the precision of the micrometer screw readings.

In the analysis of a mixture in which both constituents are in about the same proportion, the precision of the results depends equally on the precisions of the readings and of that of their individual indices of refraction.

In this last case it is advisable not to use the formula $p_2 = d_2 a \frac{N'' - N_1'}{N_2 - N_1}$, but to standardize the apparatus by comparison with chemical analyses.

Differences of pressure up to ± 5 mm. of water and of temperature up to ± 0.1 deg. C. of the gases in the chambers G , G' can be considered as having practically no influence on the error in the final result.

ARRANGEMENTS FOR INDUSTRIAL GAS ANALYSES

Figs. 5 and 6 show convenient arrangements for the industrial analyses of gases by Lord Rayleigh's interferometer. The water bath brings the gases to the same temperature. The equality of pressure of the gases is obtained in the first arrangement (Fig. 5) by adjusting the clamps and in the second case (Fig. 6) by putting the gas chambers G and G' in communication with the atmosphere through the 3-way stopcocks.

The first arrangement is preferable when frequent readings are required, say every 5 seconds. The second arrangement gives more accurate results, and is simpler and easier to handle, but the readings can be taken only every 15 to 20 seconds.

ANALYSIS OF TERNARY GAS MIXTURES

If p_1 , p_2 , p_3 are the weights of the constituents contained in the unit volumes of the mixture; d_1 , d_2 , d_3 their relative densities, N_1 , N_2 , N_3 their refraction in-

FIG. 6

FIG. 7

dices, the relation (3) given for binary gas mixtures becomes

$$N''N' = (N_2 - N_1) \frac{p_2}{d_2 a} + (N_3 - N_1) \frac{p_3}{d_3 a} \quad (4)$$

Calculation of Hydrometer Degrees, Gravities and Weights With the Slide Rule

BY WALLACE SAVAGE

IN THE two hundred and forty-odd years since Robert Boyle designed the first hydrometer, it almost seems that a new modification has made an appearance on an average of once a year. Fortunately the styles that have disappeared have accounted for about two centuries of this time. The remaining twoscore must have some *raison d'être* to account for their survival. No doubt the hydrometer is the simplest weighing device existent from a mechanical construction point of view. It is based on the principle of Archimedes, viz., *a body immersed in a liquid loses, by virtue of the surrounding particles, a weight equal to that of the liquid displaced by it.*

Archimedes was led to the discovery of this principle while trying to determine whether the new crown of the king of Syracuse was pure gold as represented by the goldsmith or not. Finding that the crown did not bear the 19.3 ratio to water as should be exhibited by pure gold, and was considerably less, Archimedes was able to demonstrate the fraud conclusively. Boyle's problem had a certain similarity. In 1675 counterfeit guineas were quite prevalent in England and the first hydrometer was devised by him with a clip at the base so that the guinea to be inspected could be suspended from the float. Counterfeit guineas were always too light to sink the float to the indicator mark.

CLASSES OF HYDROMETERS

Up to the present time there have been two types of hydrometers—constant volume and constant weight. The former is used mostly for determining the density of solids and is not of industrial importance. Nicholson's apparatus is the classical one. The constant weight hydrometer is used for gravity determinations of liquids and, next to the thermometer, it is the most widely applied instrument in the manufacturing industries. Because of the importance of temperature corrections, a mercury thermometer is often built into the spindle and the instrument is then called a thermohydrometer.

Here there is one relation in which there are two unknown factors, p and p_1 . A second relation is required. This can be obtained by absorbing one of the reagents in the absorption tubes, but the operation is impracticable. It can therefore be stated for mixtures composed of more than two gases, the interferometric method does not present any advantage over the standard volumetric or gravimetric methods.

In case one of the constituents of a ternary gas mixture is not taken into consideration the problem reverts to the analysis of a binary mixture.

An illustrative example of the value of the interferometric method in the analysis of binary gas mixtures is best shown by the diagram, Fig. 7. This gives the results obtained by interferometric analyses of an ether-air mixture from a nitrocellulose powder factory. The variations in the ether content, although very rapid, are easily recorded. No known chemical method could give similar or nearly similar reliable results.

Constant weight hydrometers have four types of scales:

Density hydrometers, indicating density of a specified liquid, at a stated temperature, in specified units.

Specific-gravity hydrometers, indicating the relative density of a specified liquid at a stated temperature to water at a stated temperature.

Per cent hydrometers, indicating, at a stated temperature, the percentage of a specified material in its aqueous solution.

Arbitrary scale hydrometers, indicating, at a stated temperature, degrees having an arbitrary but fixed relation to specific gravity.

Density and specific-gravity hydrometers need no elucidation. They did not find favor with the old-time instrument makers partly because they have a variable length scale which is difficult to graduate on the stem of the instrument. Halves, quarters, eighths, sixteenths and thirty-seconds or submultiples of 360 were the only paths beaten into the early mathematical instrument realm. To the average mind of the centuries prior to our own, decimal fractions were not even to be considered. Without doubt there is much virtue in the simple integer "degree" scales. For instance take 66 deg. Baumé oil of vitriol. Who would prefer to memorize 1.8354 sp.gr. or try to teach it to acid plant workmen? No doubt the per cent hydrometer is the instrument of the future. However, some substances such as sulphuric acid do not lend themselves well to this type of instrument. In an accompanying chart, several degree scales, solution gravities, etc., have been plotted. From these curves and lines, all the equivalents can readily be obtained.

The first thing to be noticed is that the salts such as sodium hydroxide and the chlorides of sodium, hydrogen, calcium give approximately straight lines and are thus more or less additive. The oxy-acids, such as nitric and sulphuric, exhibit peculiar curves and, due to the compression of solvent, do not take on the expected increments in solution gravity corresponding to the increments in solute mass. Alcohol acts similarly, giving large shrinkages. Usually in the distillery trade, the term degree proof is used and is simply twice the volume per cent. Thus ethyl alcohol of 0.900 sp.gr., is 66 vol. per cent, 132 deg. proof, 25.4 deg. Baumé and weighs 7.5 lb. gal., 56.0 lb. cu.ft.

ARBITRARY SCALE HYDROMETER MODULI

With the exception of the Twaddle, Barkometer, Lactometer, etc., scales, the arbitrary scale heavier than water hydrometers of Baumé, Beck, Cartier, Gay-Lussac, Balling, Brix, Fischer, Greiner and Stoppani all fall under the formula $\text{Deg.} = M(S - 1) \div S$, where M has a special value for each scale. The former three are more simple, being expressed by the formula $\text{Deg.} = M(S - 1)$. The lighter-than-water scales follow logically, having the formula: $\text{Deg.} = M(1 - S) \div S$ in the case of all but the Baumé and Cartier scales, where 10 and 10.7 are added respectively to the calculated degrees. See table opposite.

GRAVITY CONVERSIONS ON THE SLIDE RULE

1. 1.60 Specific Gravity = 54.4 Deg. B _h U.S.B.S.	54.4	=	0.6
	145	=	1.6
2. 40 Deg. B _h U.S.B.S. = 1.381 Sp.Gr.	40	=	0.381
	145	=	1.381
3. 20 Deg. B _h U.S.B.S. = 0.933 Sp.Gr.	10(+10)	=	0.666
	140	=	0.933
4. 0.70 Sp.Gr. = 60 Deg. B _h U.S.B.S.	60(+10)	=	0.3
	140	=	0.7
5. 43 Deg. B _h Gerlach = 1.415:	43	=	0.415
	146.78	=	1.415
6. 1.666 Sp.Gr. = 133.2 Deg. Twaddle:	133.2	=	0.666
	200	=	1

Unfortunately the most prominent of the arbitrary scale hydrometers, the Baumé, has at least eight values of M . This is a considerable improvement since 1881, when Prof. Charles F. Chandler² found 23. In 1904, the U. S. Bureau of Standards adopted 145 and 140 as the moduli of the heavy and light Baumé scales. These are based on 60 deg. F. determinations. Most of the petroleum hydrometers manufactured by Tagliabue in use have a modulus of 141.5. The other heavier-than-water Baumé moduli are 144, 144.3, 145.88, 146.3 and 146.78, varying from 4 to 17.5 deg. C.

The table below gives in the form of proportions the formulae expressing the relation between specific gravity and hydrometer degrees. The six settings on the slide rule illustrate the application of these proportions with the light and heavy Baumé scales as well as the Twaddle scale. As American chemists will be concerned mainly with the U. S. Bureau of Standards Baumé scale, it should be noted that the value of the modulus is a function of the temperature. By determining the modulus, " m ," at any temperature of a d degree liquid, degrees corrected for temperatures can be quickly calculated by setting $d : m :: D : M$.

HYDROMETER DEGREE SLIDE RULE FORMULAE

	Heavier Than Water $D = \frac{S-1}{S}$	Lighter Than Water $D = \frac{1-S}{S}$
Gay-Lussac	$\frac{100}{S} = \frac{D}{100}$	$\frac{100}{S} = \frac{D}{100}$
Cartier	$\frac{D+10.7}{126.1} = \frac{S-1}{S}$	$\frac{D+10.7}{126.1} = \frac{1-S}{S}$
Baumé, U. S. B. S.	$\frac{D}{145} = \frac{S-1}{S} \quad (60^{\circ}\text{F.})$	$\frac{D}{140} = \frac{1-S}{S} \quad (60^{\circ}\text{F.})$
Tagliabue		$\frac{D}{141.5} = \frac{1-S}{S} \quad (60^{\circ}\text{F.})$
"Old Holland"	$\frac{D}{144} = \frac{S-1}{S}$	$\frac{D}{144} = \frac{1-S}{S} \quad (4^{\circ}\text{C.})$
Gerlach	$\frac{D}{146.78} = \frac{S-1}{S}$	$\frac{D}{146.78} = \frac{1-S}{S} \quad (17.5^{\circ}\text{C.})$
Stoppani	$\frac{D}{166} = \frac{S-1}{S}$	$\frac{D}{166} = \frac{1-S}{S}$
Beck	$\frac{D}{170} = \frac{S-1}{S}$	$\frac{D}{170} = \frac{1-S}{S}$
Balling (not for sugar)	$\frac{D}{200} = \frac{S-1}{S}$	$\frac{D}{200} = \frac{1-S}{S}$
Brix Fischer Greiner	$\frac{D}{400} = \frac{S-1}{S}$	$\frac{D}{400} = \frac{1-S}{S}$
Twaddle	$\frac{D}{200} = \frac{S-1}{S}$	
Barkometer Lactometer	$\frac{D}{100} = \frac{S-1}{S}$	

The slide rule offers a most excellent medium for determining either an unknown modulus from values of D and S or either of the latter, when the two others are given. D can be determined to three significant figures, which is with as good a degree of accuracy as the best hydrometers can be read. Differences in the various Baumé scales are easily determined, as will be observed from the settings given. Some practice will be required in picking out the ratios $(S - 1)/S$ and $(1 - S)/S$ when calculating specific gravities from hydrometer readings. Adding and subtracting constants is also awkward at first. Temperature conversions should be practiced by setting 5 to 9 and reading the corresponding scales less 40. Thus 140 will be found opposite 252 on the scale and by reading 40 less, 100 deg. C. is read equivalent to 212 deg. F. The basis of this method of conversion is the fact that -40 deg. F. corresponds to -40 deg. C.

Weights per gal. or cu.ft. are obtained by setting S over 12 or 16 respectively. Thus 1 gal. of 100 deg. B_h tanning extract has a sp.gr. of 1.100 and weighs 9.16 lb. One cu.ft. of 54.4 deg. Baumé sulphuric acid, sp.gr. 1.60, weighs 100 lb.

¹Old Holland does not add 10.²National Academy of Science, 1881.

Determination of Maltose Conversions

By F. E. COOMBS

IN THE technical production of maltose and maltodextrine, iodine solution is generally used as an indicator of completed process, but in the writer's experience this has been found highly unsatisfactory.

Its use is limited to establishing in a gelatinized starch solution, or suspension, the point where all of the "normal" starch has been altered; but it by no means shows what part of the starch has gone completely over into maltose when, as is oftentimes the case, the desired product is to carry more or less dextrine along with the maltose, and most often some profitable object is attained by carrying a fixed percentage of dextrine and of maltose in the finished material. Further, if raw ground malt has been added to the cooked starch-mass in the converter, a certain amount of raw starch is introduced with it which, at conversion temperatures, is not gelatinized or hydrolized. This persists, and if the iodine reaction is relied upon the process is needlessly prolonged. Polarimetric methods are intricate and too slow for use as control of a going conversion.

QUICK AND SATISFACTORY METHOD

The subject of this paper is a quick and satisfactory technical method for the control of malt-conversions which the writer has found reasonably accurate, capable of use by an average attendant, and which will enable him to stop a conversion at any predetermined ratio of maltose to dextrine.

On starting the conversion and as soon as the contents of the tank are homogeneous, a sample is taken, through a fine brass gauze strainer, into a flask large enough to contain more than a filling for a hydrometer jar. The sample is cooled in the flask under a tap to a standard temperature and a spindle reading taken at that temperature. From a table later described and calculated for some desired balance of maltose-to-dextrine, there is then read off a number of cubic centimeters corresponding to a fixed weight—conveniently 10 g.—of the sample at the observed density, and this volume is then measured with a graduated pipette into a flask, made up to, say, 150 cc. with distilled water, well shaken, and a burette filled to zero with the diluted sample. From the burette a prescribed number of cubic centimeters is run into 10 cc. of freshly mixed, boiling Soxhlet solution and boiled for a minute or two. Should the added volume of dilute sample fail to reduce all of the copper, as indicated by the blue color remaining after the boiling in the clear upper portion of the test, then the conversion is known not to be completed to the required point and is allowed to go on.

COMPLETION OF THE TEST

During progress of the cook, these tests are repeated at intervals judged by the rate of disappearance of the blue color, until a final test shows its entire or almost complete absence, when the conversion is immediately stopped by admitting steam to an ample coil in the converter tank. A small bench near the converter is provided with the needed apparatus, including a rack carrying a series of 10-in. test tubes ready filled with 10 cc. charges of mixed Soxhlet solution. At this bench is posted a typed table showing the constants to be followed in making the tests, such tables being kept

in readiness and separate ones made for each material change in the maltose-dextrine ratios that may be wanted from time to time.

CALCULATION OF TABLES

The calculation of the tables is simple and is based on the fact that, for practical purposes, the specific gravity influence of the two components, in solution, is the same for the same percentages contained. Each table has three columns, the first showing the range of densities B, in half degrees (or Brix in whole degrees) covering the maximum fluctuation of the converter liquors; a second column shows the number of cubic centimeters equal to 10 g. of a sample at the listed densities; the last vertical parallel column indicates the volume of diluted sample to be run into the Soxhlet tube from the burette, and which will just reduce the copper therein when the total solids are one-half, two-thirds, or whatever is desired in maltose content in the finished product in ratio to the dextrine remaining unconverted.

The test, including taking and cooling the sample, can be made in less than five minutes, is within the ability of any operative intelligent enough to trust with conducting a process kettle, and it will insure uniform composition of the conversion product.

It is recommended that the light provided for doing the reduction test should be a good incandescent (nitrogen-filled) lamp, as in that case the men are not confused in judging the color by changes of weather or alternation from day to night shifts, and once having caught the proper appearance of an exact reduction, this will not vary.

TABLE I—TABLE FOR MALTOSE CONVERTER CONTROL

(Total solids of finished product to contain 50 per cent maltose)		
Per Cent Solids (Deg. Brix)	Volume Converter Liquor = 10 g. cc.	Dilute Liquor From Burette
13.0	9.5	18.6
13.5	9.5	17.9
14.0	9.5	17.5
14.5	9.4	16.8
15.0	9.4	16.2
15.5	9.4	15.6
16.0	9.4	15.1
16.5	9.4	14.6
17.0	9.4	14.2
17.5	9.3	13.8
18.0	9.3	13.5
18.5	9.3	13.1
19.0	9.2	12.8
19.5	9.2	12.5
20.0	9.2	12.2
20.5	9.2	11.8

The general formula for a table such as the one given would be

$$100 \left(0.0807 + \frac{\text{Sp. gr.} \times \text{Brix} \times a x}{150} \right) = y$$

In which

0.0807 = grams maltose to reduce 10 cc. Soxhlet solution.

Sp. gr. = Specific gravity of converter contents.

a = Per cent maltose desired in total solids, as a decimal expression.

x = $\frac{10}{\text{Sp. gr.}} =$ cubic centimeters of original converter liquor to be diluted to 150 cc.

and y = Cubic centimeters of diluted liquor to be delivered from burette into 10 cc. of Soxhlet solution, and which will just reduce the copper therein when the predetermined percentage of maltose has been reached.

If the table is to be based on a uniform measured volume of 10 cc. of original converter liquor, then, with the same constants as above, the formula becomes

$$100 \left(0.0807 + \frac{10 \text{ Sp. gr.} \times \text{Brix} \times a}{150} \right) = y$$

In the first column of Table I the usual range of densities of the converter liquor is covered, stated as degrees Brix, and assuming that the liquor has been strained carefully and cooled to not above 20 deg. C.

G. L. Spencer's "Handbook for Sugar Manufacturers," edition of 1906, carries a table of specific gravities parallel to degrees Brix, which has been used in the calculation of the table.

If, then, 10 g. be divided by the specific gravity corresponding to, say, 15 deg. Brix (1.061), 9.42 cc. will be found as the nearest equivalent volume, and can conveniently be measured out as 9.4 cc. for a working quantity, and in this way the second column of the table is derived. Having measured this volume and diluted it to 150 cc., each cubic centimeter will represent 0.06667 g. of the original converter liquor, and $0.06667 \times .15$ (decimal expression of the total solids) will give the weight of the original solids now contained in the diluted liquor, per cubic centimeter, or 0.01 g. And if 50 per cent of the total solids are to be maltose, each cc. of the diluted liquor should contain 0.005 g. maltose when conversion has progressed to the desired stage. And since each measured portion of Soxhlet solution corresponds to 0.0807 g. of maltose,

then $\frac{0.0807}{0.005} = 16.14$ cc., or the volume required to be run from the burette to reduce all the copper of the Soxhlet solution. But the burette will not measure closer than 0.1 cc., and if 16.1 is taken, it will be found by retrogressive calculation that $\frac{0.0807}{16.1} = 0.0050124$ g.

as the weight of maltose per 1 cc. of the diluted liquor. This weight divided by $\frac{(1.061 \times 9.4) .15}{150} = 0.5025$ plus.

In this case decimal errors have been cumulative in one direction, as only tenths of cubic centimeters can be regarded in measurements ordinarily. For this reason, 16.2 cc. is used in the table, and this figure, by the preceding calculation, will give 49.94 per cent maltose, which is close enough for factory purposes. Control tables of this nature must always be checked back and figures empirically altered to conform as nearly as possible to technical needs and the requirements of manipulation.

It is obvious that tables for this purpose may be calculated by taking a uniform volume of the converter liquor instead of a uniform approximate weight—for example, 10 cc.—and that in such a case only two columns are required, since the second one of the tables I have given might be omitted. And it is also clear that such tables will serve as well for the working of acid hydrolysis in dextrose conversion from starch.

San Francisco, Cal.

A Town for Sale

The War Department is offering for sale the town of Nitro, West Virginia, a complete industrial community embracing 737 manufacturing buildings housing accommodations for 20,000 persons and the utilities and civic improvements that constitute the conveniences of a modern city. Nitro, built by the Government at a cost of approximately \$70,000,000, is the site of the second largest smokeless powder plant in the world. The bids, which must cover not only the powder plant and the other industrial units which were erected to prepare the ingredients essential to powder making, but the civic community as well, to which the United States also holds title, will be opened at 12 o'clock noon on Sept. 30, 1919, at the office of the Chairman of the Ordnance District Salvage Board, 1710 Market St., Philadelphia, Pa.

Synopsis of Recent Chemical and Metallurgical Literature

Uses of Water Power and Raw Materials in the Metallurgical and Chemical Industries in France.—In the May-June, 1918, issue of *La Houille Blanche* Mr. E. F. CÔTE described at length the bright side of the potential value of the Rhone waterfalls, and gave in conclusion a table on the water power and raw materials used in electrometallurgical and chemical industries. (See Table I.) In the September-October issue of *La Houille Blanche* Prof. GEORGES FLUSSIN, director of the Electrochemical and Metallurgical Laboratory of Grenoble, France, gave another table on the same subject. (See Table II.)

Both authors state that the figures are only approximate and that they vary somewhat with the apparatus used, the method of manufacturing and the composition of the raw materials. Abstracts of these tables are given as representing average French hydro-electric practice.

TABLE I.—CONSUMPTION OF HYDRO-ELECTRIC POWER AND RAW MATERIALS IN SOME CHEMICAL AND METALLURGICAL INDUSTRIES (E. F. CÔTE)

Products	Per Ton of Manufactured Product	Raw Material Handled (Tons)	Raw Materials Handled (Tons)
	Kw.-Day (24 Hr.)		Kw.-Yr (Tons)

Natural and Industrial Resources of France, Germany, Great Britain and Ireland, the United States and the World for 1913.—In a series of articles published by *L'Industrie Chimique* during the months of May to December, 1913, AGRICOLA passes in review the situation of the natural and industrial resources of France, Germany, Great Britain and Ireland, the United States and the world in 1913. The data given form a very valuable source of information on the economic status

before the war and no doubt will serve as a basis of comparison in the history of the industrial progress during the pre-war and post-war times. It is noteworthy that the United States produced about 60 per cent of the totals of cereals, cotton, oil, copper, aluminum; about 40 per cent of coal, pig iron, steel, zinc; about 30 per cent iron, lead, silver; about 20 per cent gold, etc., while its population was only about 15 per cent of the world's total.

TABLE I—COMPARATIVE DATA ON ECONOMIC, FINANCIAL AND INDUSTRIAL RESOURCES, 1913

	France	Germany	Great Britain and Ireland	United States	World

The Rubber Industry.—While the United States, as a result of intensive development of resources within its borders, materially reduced its dependence upon foreign sources of raw material during the war, it is well to remember that there are certain natural products which, for geographic reasons, must be secured from abroad. Chief among these is rubber, and the following tables¹ show the magnitude of our dependence.

The United States in 1917 consumed about 75 per cent of the rubber used in the world, as shown by Table I.

TABLE I—THE CONSUMPTION OF CRUDE RUBBER
(Long Tons)

Year	United States	Great Britain	France	Germany	Italy	Total
1910.....	42,210	20,455	3,799	13,775	2,201	82,440
1911.....	38,475	16,736	5,398	15,281	2,491	78,381
1912.....	52,964	18,724	4,633	15,643	3,872	95,836
1913.....	52,179	25,276	6,500	15,500	2,000	101,455
1914.....	61,251	18,549	5,000	11,000	4,000	99,800
1915.....	96,792	15,072	10,770	6,000	6,880	135,214
1916.....	116,477	26,760	14,685	3,000	8,552	169,474
1917.....	177,088	25,983	17,000	2,000	6,946	229,017

During 1917 Far Eastern plantations produced about 79.5 per cent of the world's supply of crude rubber; the British colonies turned out approximately 80 per cent of this, or 63 per cent of the total production of the world. The only American possession suitable for the growing of rubber is the Philippines, and they produced the insignificant total of 147 tons in 1917, or sufficient to last one of the large American manufacturers about one day.

Table II shows the world's production of crude rubber from 1900 to 1919, inclusive, the quantities being given in long tons (2240 pounds), and the statistics for plantation and Brazil rubber being given separately.

TABLE II—PRODUCTION OF CRUDE RUBBER

Year	Plan-tation	Brazil	Other Kinds	Total
1900.....	4	26,750	27,136	53,890
1901.....	5	30,300	24,545	54,850
1902.....	8	28,700	23,632	52,440

1904.....	43	30,000	32,077	62,120
1905.....	145	35,000	27,000	62,145
1906.....	510	36,000	29,200	66,210
1907.....	1,000	38,000	30,000	69,000
1908.....	1,800	39,000	24,600	65,400
1909.....	3,600	42,000	24,000	69,600
1910.....	8,200	40,800	21,500	70,500
1911.....	14,419	37,730	23,000	75,149
1912.....	28,518	42,410	28,000	98,928
1913.....	47,618	39,370	21,452	108,440
1914.....	71,380	37,000	12,000	120,380
1915.....	107,867	37,220	13,615	158,702
1916.....	152,650	36,500	12,448	201,598
1917.....	204,251	39,370	13,258	256,879
1918*.....	210,000	38,000	12,000	260,000
1919*.....	240,000	38,000	12,000	290,000

*Estimated.

Indications are that plantations will henceforth furnish an increasing proportion of the world's supply of crude rubber. The difficulties of producing wild rubber in sufficient quantities in Brazil and other districts, together with its high cost of production and the superior, clean condition of plantation rubber, render the gathering of wild rubber disadvantageous compared with plantation rubber. It is said that the cost of production of plantation rubber averages approximately 25c. gold per lb. f.o.b. Far East, whereas Up River fine cannot be produced profitably under 55c. per lb. f.o.b. Brazil.

It is notable that 76 per cent of planted acreage of plantation rubber is owned by British capital, and 2.8

per cent by American capital, according to best available authorities, as shown by Table III.

TABLE III—OWNERSHIP OF PLANTATIONS

Plantation Interests	Average	Per Cent
British.....	1,513,576	75.9
Dutch.....	260,000	13.0
French and Belgian.....	100,000	5.0
American.....	55,000	2.8
German.....	1,400	0.2
All other.....	61,577	3.1
Total.....	1,995,553	100.0

The 55,000 acres planted and controlled by American capital comprise the estate of the General Rubber Co., in Sumatra. American interests have also recently acquired 40,000 acres of undeveloped land in Sumatra. A very limited area is also planted to rubber in Mindanao, Philippines.

A graphic idea of the growth of the plantation rubber industry may be derived from Table IV, giving the estimated acreages in bearing, number of tons production, number of pounds per acre, and the percentage of increase for the years 1900 to 1922, inclusive. The estimates of acreage in bearing for 1920, 1921 and 1922 are based upon present planted acreage, additional areas of which will become productive.

TABLE IV—GROWTH OF PLANTATION RUBBER INDUSTRY

Year	Estimated Acreage in Bearing	Tons	Increase, Per Cent.	Lb. per Acre Planted	Bearing
1900.....	4				
1901.....	5	25			
1902.....	8	60

1917.....	1,448,033	204,251	34	229	316
1918.....	1,611,124				
1919.....	1,727,820				
1920.....	1,729,795				
1921.....	1,915,553				
1922.....	1,995,553				

Rubber is perhaps the only important staple which has not experienced an increase in price during the period of the world war. The reason is at once apparent from a study of the figures given in Table IV. Large acreages, planted years before, began to bear during the war period, so that production not only kept pace with the increasing demand, but actually exceeded it, resulting in lower prices. Table V shows the downward trend of the price of crude plantation hevea, first latex crêpe, in the New York market.

TABLE V—PRICE OF CRUDE PLANTATION RUBBER*

	Jan.	Apr.	July.	Oct.
1913.....	1.10	0.95	0.70	0.52
1914.....	0.56	0.63	0.55	0.61
1915.....	0.86	0.62	0.63	0.59
1916.....	0.92	0.82	0.58	0.61
1917.....	0.80	0.80	0.67	0.63
1918.....	0.57	0.60	0.63	0.59
1919.....	0.55	0.49	0.40	

*Commer. Monthly (National Bank of Commerce, New York), September, 1919

A fraction over 66 per cent of all rubber plantations are situated in British colonies, so that Great Britain exercises both political and financial control over the supply of this important raw material. Of the total acreage under British control, 807,491 acres are in the Federated Malay States and Johore, 159,500 acres in the Straits Settlements, 251,500 in Ceylon, 41,820 in South India, 29,880 in British Borneo, 26,390 in British Burma, and 5000 in the South Sea Islands. Under

¹Commerce Reports, Aug. 1, 1919, pp. 668-671; Crude Rubber Prices, by Isador Lubin, Price Bulletin No. 30, War Industries Board (reprinted in *India Rubber World*, Sept. 1, 1919, pp. 685-688).

the Dutch flag there are 352,455 acres in Sumatra, 238,830 acres in Java, and 10,100 acres in Dutch Borneo, giving the Netherlands political control over 49 per cent of the total world acreage in rubber plantations. France controls 10,000 acres in Cochín China, and the share of all other countries amounts to 62,577 acres. An almost unlimited area of desirable land for rubber plantations is yet available for development in Sumatra and Borneo; but such is not the case with the Malay Peninsula, Ceylon and Java.

The only place on American soil where conditions have been found favorable to rubber growing is the Philippine Islands, where about 147 tons were produced in Mindanao in 1917, but owing to an insufficient supply of good cheap labor (our Government prohibits the importation of Chinese coolies) and Government restriction limiting the amount of land which corporations can own to 2500 acres, the investment of American capital has been restricted and discouraged.

Metallurgical Calculations.—ADOLPH BREGMAN gives in the August, 1919, issue of *The Metal Industry*¹ an interesting note on the causes of inefficiency of melting appliances, with special reference to an oil-fired furnace. He illustrates by an example how this can be eliminated, and dwells on the necessity of preliminary calculations for an appropriate furnace. "It is an old story that it is far cheaper to change the plant on paper before it is built than after."

The data to be figured out for a given furnace which has to perform a given work are: The amount of heat needed, which is to be expressed in amount of fuel, and the air required for efficient combustion. From these data to determine the best adaptable conditions for efficient performance of the installation.

To take a definite problem:

Given a furnace which must melt 2000 lb. of copper; 4 heats per 8 hours; charging and tapping time $\frac{1}{2}$ hr. per heat, i. e. $1\frac{1}{2}$ hr. for actual melting time.

The theoretical heat necessary to melt a charge is given by

$$\text{B.t.u.} = A \times B \times (T_1 - T)$$

in which A = number of pounds of metal

B = specific heat of the metal

T = temperature of the metal before charging

T_1 = temperature of the metal when ready to tap

For copper $A = 2000$, $B = 0.095$. With $T = 60$ deg. F. and $T_1 = 2700$ deg. F., we have

$$\text{B.t.u.} = 2000 \times 0.095 \times (2700 - 60) = 501,600$$

With a factor of safety, or with a furnace efficiency of x per cent, the actual heat units required will be $501,600 \div x$. The actual factor of safety is to be considered according to local conditions. With $x = \text{say } 15$, the actual heat units required will be $501,600 \div 0.15 = 3,344,000$ B.t.u.

Using as fuel an oil of say 140,000 B.t.u. per gallon the amount required will be $3,344,000 \div 140,000 = 23.9$ gallons.

The time limit for a melt being $1\frac{1}{2}$ hr., the consumption of oil per hour will be, say, 16 gal. The oil pump and burners must be carefully chosen for size and ease of adjustment. To burn the oil efficiently a well

defined amount of air is required. The chemical reactions of combustion are:

i. e., one part C requires 2.67 parts O and one part H requires 8 parts O.

The oxygen content of the air being 23.1 per cent by weight, the amount of air required will be: $2.67 \div 0.231 = 11.55$ lb. per lb. of C and $8 \div 0.231 = 34.64$ lb. per lb. of H. For practical purposes the average composition of fuel oil may be taken as 85 per cent C and 12 per cent H, the remainder being sulphur, nitrogen, etc., which need not be considered here. With this grade of oil the total amount of air per lb. of fuel is $A = (11.55 \times 0.85) + (34.64 \times 0.12) = 13.97$, say 14 lb.

Taking 7.5 lb. oil per gal., the theoretical weight of air required per gal. of oil is $7.5 \times 14 = 105$ lb. One lb. of air at sea level at 60 deg. F. is equivalent to 13.14 cu.ft., and 105 lb. corresponds to $105 \times 13.14 = 1379.7$, say 1380 cu.ft. This figure represents the theoretical volume of air necessary to burn 1 gal. of oil. In actual practice it takes from 10 to 20 per cent more air to do the work. In order to be quite safe, one should allow 2000 cu.ft. of free air at ordinary temperature for every gallon of oil to be burned. With 16 gal. of oil per hour, we need $2000 \times 16 = 32,000$ cu. ft., i. e., $32,000 \div 60 = \text{say, } 533$ cu.ft. air per minute.

The blower must be of sufficient size to handle the capacity. There is no fixed oil or air pressure for all burners. This can be determined only by the needs of the particular burner used. A logical use of air and oil gages will solve this problem.

It is excellent practice to preheat the oil to a temperature of about 20 to 25 deg. below the flash point. When using heavy crude oil this is absolutely necessary. Air also should be preheated to the temperature of the oil. It must be remembered, however, that if the air is heated due allowance must be made for its expansion and the consequent dilution as regards the proportion of oxygen. This can always be calculated from the formula

$$W = 0.080728 \times \frac{P \times 491.6}{14.6963 \times T \times 459.6}$$

in which W = weight of cu.ft. of air

P = barometric pressure in lb. per sq.in.

T = temperature in degrees F.

In addition the air, especially at low pressure, loses much of its pressure if it has a long travel. It is best to eliminate all avoidable bends and elbows.

Recovery of Zinc From Low-Grade and Complex Ores.—The Bureau of Mines Salt Lake City Station has co-operated with the Department of Metallurgical Research of the University of Utah in studying the possibility of devising new processes for the recovery of zinc from ores. Certain ores too low grade or complex to permit of profitable treatment by the retort process have been the subject of the research reported in Bulletin No. 168, Bureau of Mines, by DORSEY A. LYON and OLIVER C. RALSTON. The work reported in this bulletin covers only the concentration of zinc ores and the hydrometallurgy of zinc. Sulphide and oxidized ores were studied. Investigation included concentration tests by gravity and flotation; chloridizing sulphate, oxidizing and mag-

¹Adolph Bregman, "Metallurgical Calculations," *Metal Ind.*, vol. 17, No. 8, August, 1919, pp. 363-370.

netic roasting; acid and alkaline leaching; precipitation of the metal both electrolytically and chemically. Tests were made to determine the suitability of the ores to concentration by igneous and magnetic processes.

Acyclic and Saturated Cyclic Hydrocarbons.—The June 30, 1919, issue of *Comptes Rendus* contains the results of the work of Messrs. G. CHAVANNE and J. L. SIMON on the preparation and the critical temperature of dissolution in aniline of some acyclic and saturated cyclic volatile hydrocarbons contained in petroleum distillates. They have studied the following products: Acyclic carbides: normal pentane and isopentane, normal hexane and isohexane, synthetic isohexane, isopentane, heptane, and octane. Saturated cyclic carbides: cyclohexane, methylcyclohexane, the three dimethylcyclohexanes, cyclopentane and methylcyclopentane. They also state that the use of manganous carbonate as a catalytic agent has proved to be particularly efficient in the transformation of butyric, adipic and methyladipic acids into the corresponding acetones (*Compt. Rend.*, T. 168, No. 26, June 30, 1919, pp. 1324-1326).

Recent Chemical and Metallurgical Patents

Complete specifications of any United States patents may be obtained by remitting 5c. each to the Commissioner of Patents, Washington, D. C.

Manufacture of Manganese Steel.—SIR ROBERT HADFIELD of Westminster, England, has developed a high silicon manganese steel which, when heated to between 900 and 1050 deg. C. and then quenched in water, is particularly suitable for use in helmets, body shields and as protective armor for aircraft. Sheets of the following composition when toughened have been found of superior quality: Fe 84.08 per cent, C 1.04 per cent, Si 1.42 per cent, Mn 12.65 per cent, Cr 0.81 per cent. Aluminum may replace silicon up to about equal parts of each, and nickel, cobalt, vanadium, tungsten or titanium, or a combination of these elements, may be used to modify or improve the qualities of the alloy. (1,310,528, July 22, 1919.)

Chloroform From Carbon Tetrachloride.—The present invention relates to certain improvements in the process of manufacturing chloroform described by A. W. SMITH in U. S. P. 753,325. That process involved the separate production of carbon bisulphide and sulphur dichloride, the interaction of these substances to produce carbon tetrachloride and the reduction of carbon tetrachloride to chloroform by agitating with finely divided metallic iron in a suitable reaction vessel. The principal reaction taking place is that indicated by the following equation:

The temperature during this reaction must, however, be carefully controlled, since, if allowed to rise, the chloroform is also reduced:

At such higher temperatures, other decomposition products of carbon tetrachloride are also formed. The method first employed consisted in placing the mixture of carbon tetrachloride and water in a double-walled vessel provided with means for circulating water between the two portions of the shell so that the tempera-

ture could be kept at about 20 deg. C. Iron filings were then added in successive small portions. It was found, however, that, working at a temperature low enough to prevent the formation of appreciable quantities of dichloromethane, the speed of reduction was extremely slow. Using a higher temperature, the yield was considerably lower due to over-reduction and the possibility of over-reduction increased directly with the amount of chloroform present, so that it was impractical to reduce more than 50 per cent of the carbon tetrachloride. At this point, the temperature was raised and the mixture of CCl_4 , CHCl_3 , CH_2Cl_2 , etc., distilled off, yielding in impure chloroform which had to be treated by an expensive process of fractional distillation.

HERBERT H. DOW and WILLIAM O. QUAYLE have found that many of these difficulties may be avoided by using diminished pressure so that the chloroform, as formed, distills off with a certain amount of CCl_4 , which is easily separated in the condenser and returned to the reaction chamber. The rapid removal of the CHCl_3 from the reaction zone minimizes the opportunity for further reduction and consequently a higher temperature may safely be used, thus increasing the speed of the reaction. Furthermore, all of the iron or other reducing agent may be added at one time. (1,311,329; assigned to the Dow Chemical Co.; July 29, 1919.)

Method of Removing Certain Impurities From Electrolytic Cells.—HUGH K. MOORE of Berlin, N. H., notes that the gelatinous compounds of calcium and magnesium which deposit in the interstices of the cathode and form on the diaphragm of an electrolytic chlorine cell may be decomposed by filling the anode compartment of the emptied cell with a dilute solution of lactic acid. This acid solution is fed continuously to the cell through the usual float valve, washing the soluble reaction products away from the diaphragm, the cell being by-passed during the operation. The acid forms water-soluble lactates of calcium and magnesium, and the 0.8 per cent solution recommended is not of sufficient strength to dissolve iron to any appreciable extent. (1,309,214, July 8, 1919; assigned to the Brown Co. of Berlin, N. H.)

Separation of Materials by Gravity.—RICHARD L. LLOYD of New York City finds that the slag losses of metals or of matte can be reduced fully one-sixth by specially designed forehearth. In this hearth the incoming material is conducted to the bottom of the hearth, and the slag, rising upward through the metal or matte, is washed of metal values. The entire contents of the hearth are also agitated, assisting in the recovery. (1,310,998, July 22, 1919; assigned to the Dwight & Lloyd Metallurgical Co. of New York.)

Automatic Tempering-Machine for Tools.—CLARENCE O. STEE and KARL H. KOLHED of Cerro de Pasco, Peru, take advantage of the fact that tool-steel heated above its critical temperature is non-magnetic in designing an automatic machine for tempering tools. The apparatus consists of an electromagnet arranged as the weight of a pendulum; when the steel is above the critical temperature the electromagnetic pendulum controls the support upon which the heated tool to be tempered is placed. As the tool cools, becoming magnetic, the electromagnet is attracted to the tool, swinging far enough to make a contact, which in turn energizes a second electromagnet. This magnet

releases the support which holds the tool, thereby dropping it into the quenching bath. The apparatus is designed primarily for tempering rock-drills. (1,311,722; July 29, 1919.)

Treatment of Ores for Production of Metal and of Potassium Compounds.—CHARLES CUTLETT of Staunton, Va., increases the recovery of potassium in a soluble form from iron blast-furnaces or from other blast-furnaces where the ore contains potassium compounds, by adding salt in small amounts to the charge. The addition of calcium fluoride also tends to produce a slag containing a smaller amount of potash. The volatilized potassium compounds, in this case the chloride, are recovered from the fume and dust by the usual methods. (1,311,043, July 22, 1919; assigned to the British Potash Co., Ltd., of London.)

Apparatus for Extracting Metals From Their Ores.—EDMUND S. LEAVER of Tucson, Arizona, uses sulphurous acid as a leaching agent, in a rotating drum of special construction, for treating ores which contain copper oxides or carbonates. The pulverized ores,

FIG. 1

in the form of pulp, containing about 5 per cent solids, is fed in at the opposite end of this drum from the SO_2 gases, and the flow of pulp and gases so controlled that the temperature of the discharged pulp is about 40 deg. C. At this temperature SO_2 is but slightly soluble

FIG. 2

in water. The gases carry an excess of oxygen, which oxidizes the sulphites to sulphates. The discharged pulp therefore contains the metals as sulphates and the exit gases are low in SO_2 . The construction of the apparatus is shown in the figures. Fig. 1 is a longitudinal section. The gases from the sulphur burner or roasting furnace 6 are forced by fan 7 into the drum 1, which revolves on trunnions 2. The pulp is fed in and excess gases pass out through 3. The

drum is fitted with partitions 17, perforated as at 19 and 20 in Fig. 2. Buckets 13 are provided on the inner circumference of the drum which lift the pulp and dump it on the slats, shown in section 24, by the revolution in direction of the arrow. (1,312,488, Aug. 5, 1919; one-half assigned to Chas. E. Van Barneveld.)

British Patents

Complete specifications of any British patents may be obtained by remitting 25c. each to the Superintendent, British Patent Office, Southamton Buildings, Chancery Lane, London, England.

Alkali Dichromates.—An alkali chromate solution is treated with carbonic acid and ammonia, preferably in the presence of ammonium carbonate in excess. Sodium bicarbonate is precipitated and removed, and the solution is then heated to remove ammonia and ammonium carbonate, and lime is added to produce calcium chromate, after which the liberated ammonia is removed by distillation. Niter cake is then added to produce alkali, dichromate and calcium sulphate, the latter being removed by filtration. (British Patent No. 122,172—1918. SOCIÉTÉ INDUSTRIELLE DE PRODUITS CHIMIQUES. Paris, March 19, 1919.)

Lead Chromate Pigments.—Basic lead acetate solution prepared from lead and acetic acid is purified by stirring with chalk or other agent that will absorb lead oxide, and the clear solution is used for the production of lead chromate pigments. Examples are given of the production of lemon chrome from purified lead acetate, acetic acid, sodium bichromate, sulphuric acid, alum and sodium sulphate, and middle chrome from purified lead acetate, acetic acid and sodium bichromate. (British Patent 123,841—1918. E. F. MORRIS, Holly Bank, Roby, near Liverpool. May 7, 1919.)

Albumens.—Soluble decolorized albumens are obtained from blood by first treating it for a considerable time with dilute acid, then adding hydrogen peroxide and allowing this to act for a considerable time, and finally neutralizing the added acid, all at ordinary temperature. Defibrinated blood is preferably used. The product may be evaporated to dryness in vacuo without losing its solubility. Instead of blood, blood cake or the like may be used. (British Patent 123,971—1918. A. J. L. TERWEN, 22 Aaksen Weimarlaan, and C. J. C. VAN HOOGENHUZZE, 8 Baustraat—both in Amsterdam. May 7, 1919.)

Treating Copper Waste.—Copper sweepings and scraps containing copper, zinc, iron, tin, antimony, silica, or other impurities, are roasted with not less than 15 per cent of common salt, silica being added if the amount present in the material to be treated is less than 25 per cent. The roasting is carried out in a two-part furnace comprising a muffle surmounted by a reverberatory furnace. Cupric or cuprous chloride is formed according to whether the roasting temperature is below or above 600 deg. C. The cupric chloride is recovered by leaching with dilute sulphuric acid or the cuprous chloride by volatilization and condensation. (British Patent 123,418—1918. C. C. CITO, 10 rue Henri Marichal, Bruxelles. April 16, 1919.)

Purifying Aluminum Salts.—Aluminum salt solutions, particularly the nitrate, are purified from iron by treatment with excess of amorphous or precipitated alumina, which may be prepared in situ by adding a soluble base to the solution, or an aluminum compound

such as calcined kaolin, clay, raw or calcined bauxite, labradorite, or anorthite. The treatment is preferably effected with heat and may be under pressure or otherwise. The solution may be stirred, or air may be blown through. Part of the iron may be precipitated by treatment with one of the minerals mentioned and the rest by precipitated alumina. The last traces of iron may be removed by ferrocyanide, the blue precipitate being absorbed in the first precipitate. If the iron is not in the ferric condition it is first oxidized. (British Patent 123,720—1918. NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI, Norske Industri-Hypotekbank, 1, Bygdö Allé, Christiania. April 30, 1919.)

Alumina.—Kaolin, clay marl, halloysite shale and the like calcined at about 500 deg. C., preferably in a reducing atmosphere, and then treated with nitric acid, or with nitrogen oxides and steam or water. The aluminum nitrate solution is separated from the residue and treated to obtain alumina, e.g., by calcining or by precipitation with ammonia. (British Patent 122,623—1918. NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI, Norske Industri - Hypotekbank, 1, Bygdö Allé, Christiania. Not yet accepted. March 26, 1919.)

Personal

Col. E. H. ABADIE has been appointed comptroller of the Division of Operations, U. S. Shipping Board, vice Mr. JOHN J. NEVIN, resigned.

Mr. J. F. BARTHOLOMEW has accepted the position as chief chemist with the Charlotte Chemical Laboratories, Inc., Charlotte, N. C., having formerly been chemical engineer for the Air Nitrates Corp., Muscle Shoals, Ala.

Dr. D. C. BYERS of the University of Washington has been appointed chief of the Division of Chemistry in the Bureau of Soils, Department of Agriculture, Washington.

Prof. H. C. COLES, who had charge of industrial chemistry at the College of the City of New York during the absence of Professor Moody, has resigned to accept a position as metallurgical expert with the Niles Tool Works Co., New York.

Dr. CHARLES H. HERTY, editor of the *Journal of Industrial and Engineering Chemistry*, sailed on Sept. 3 for Europe. Dr. Herty has been appointed by President Wilson to secure America's share of German dyes which by the terms of the Peace Treaty passed to the control of the Reparations Commission. Dr. Herty will endeavor to secure a six months' supply of vat dyes to fill the needs of consumers until vat dyes of American manufacture are on the market.

Mr. WALTER K. MALLETT has been selected to head the engineering department of the Copper Queen Branch of the Phelps Dodge Corporation and left San Francisco recently for Douglas, Ariz.

Mr. PAUL D. V. MANNING, formerly chemist with the nitrate division of the Ordnance Department, his last assignment being at the Fixed-Nitrogen Research Laboratory, American University, Washington, D. C., has accepted a position as electrometallurgist with the Chile Exploration Co., New York City.

Dr. CHARLES L. PARSONS, chief chemist of the Bureau of Mines, has resigned, and it is reported that he will enter private practice.

Dr. CHARLES L. REESE of the du Pont Company and Dr. H. S. MINER of the Welsbach Company, each received the honorary degree of Sc.D. from the University of Pennsylvania, this summer.

Dr. JAMES H. RANSOM resigned as director of the chemical department of Vanderbilt University, last May, and

has accepted a position as research chemist with the Michigan Smelting & Refining Co., of Detroit.

Mr. CHARLES H. KEPATHI is at the Calumet & Hecla works at Lake Linden, Michigan, in a consulting capacity.

Dr. THEODORE W. RICHARDS, professor of chemistry at Harvard University, has been elected president of the American Academy of Arts and Sciences.

Dr. W. H. RODERUSH has left the research laboratory of the U. S. Industrial Alcohol Co., South Baltimore, Maryland, to take a National Research Council Fellowship at the University of California, Berkeley, California.

Mr. A. A. SCHNEIDER, formerly with the Raw Materials Department of the Midvale Steel & Ordnance Co., and the Cambria Steel Co., has been appointed manager of the newly created Raw Materials Division of the American Steel Export Co.

Dr. F. W. SKIRROW, for the past four years assistant professor of chemistry at McGill University, has resigned this position to take up the duties of chief chemist to the Shawinigan Laboratories, Ltd., the newly founded research organization of the Shawinigan Water and Power Co., Shawinigan Falls, Quebec.

Mr. E. E. THUM, who has been stationed in Salt Lake City, Utah, since Jan. 1, 1918, as Western Editor of *CHEMICAL & METALLURGICAL ENGINEERING*, has been transferred to the main editorial office in New York City, and will act as Associate Editor. The new Western Editor is Mr. L. W. CHAPMAN, whose headquarters are in San Francisco.

Mr. C. H. WILDRIDGE has accepted a position with the Manitoba Steel Foundries at Selkirk, Manitoba. He was formerly with R. W. Hunt & Co., Montreal.

Current Market Reports

The Non-Ferrous Metal Market

Tuesday, Sept. 9.—No important fluctuations in market prices have taken place in the last two weeks, with the exception of zinc, which declined. Sellers are firm, volume of sales is not large, but European buyers are said to be making preparations for important deals.

Aluminum.—Transactions are largely made on direct contract between producer and consumers. The open market is not active; 98-99 per cent ingots are quoted at 32-33c. per lb., remelt at 31-32c. Scrap casting, 21-24c.; sheet scrap, 22½-23c., and clippings, 24-27½c.

Antimony.—The market is easy; spot wholesale is quoted at 8½c. and futures at 8c. lb. Small job lots, 9c. lb.

Copper.—Some resale copper is being sold at 22½c. but the market price is 23½c. lb. for September and 24c. for October.

Copper sheets, hot-rolled.....	lb.	33.50 —
Copper sheets, cold rolled.....	lb.	35.00 —
Copper bottoms.....	lb.	41.50 —
Copper rods.....	lb.	24.00 —

Scrap, No. 1 clean brass turnings.....	lb.	10½ — 11½
Scrap, No. 1 comp. turnings.....	lb.	16 — 16½

Lead.—The lead market is stronger, spot New York being 5.9-6c. lb. and East St. Louis 5.75c. lb. Cut lead sheets are bringing 9c.

Tin.—The tin market has not gathered the expected momentum downward. Straits spots are quoted at 56½c. and 99 per cent electrolytic, 55½c. lb.

Zinc.—Spot zinc has declined, but futures are quoted on a rising rate. Spot New York, 7.65c. lb.; October, 7.7c. East St. Louis spot, 7.3c.; October, 7.35c.

The Iron and Steel Market

At this writing it is uncertain whether there will be anything approaching a general strike in the iron and steel industry. The "strike committee" of the unions affiliated with the American Federation of Labor has pursued curious tactics, all suggestive that it has had doubts whether it could produce a strike by calling one and that its best chance to accomplish anything in the direction of establishing conference relations with the iron and steel manufacturers was to play the strike threat to the utmost. Strikes, being a species of mob psychology, are not welcome in the realm of prediction.

Production of steel ingots in August was at the rate of about 39,100,000 tons a year, or a 10 per cent better rate than that of July, and equal to about 80 per cent of capacity, conservatively estimated. One striking feature of the situation is that one could not count up anything like 20 per cent of idle capacity. Either the managements of various works intentionally refrained from pushing for tonnage, which is altogether improbable, or labor indifference prevented plant units from producing their normal tonnages.

PIG IRON PRODUCTION 80 PER CENT OF CAPACITY

From the efficiency standpoint pig iron makes a better showing, as the rate of production in the first half of September was approximately 80 per cent of estimated capacity, and with many furnaces idle, easily sufficient to count up 20 per cent, without including furnaces that are probably unfit. Conditions as to the unfitness of furnaces have changed, however, and it is improbable that there are furnaces equal to one-fourth the furnace capacity now active that can produce without loss in present conditions. A fundamental change has occurred whereby the labor cost per ton has increased much more at some furnaces than at others, due to high wage rates. Before the war there was more or less equalization, furnaces with low investment and high labor employment having some opportunity to compete with furnaces having low labor employment and heavy investment. In many quarters, therefore, there are predictions that with broader demand pig iron prices must advance. That may easily occur. Relative to finished steel products pig iron prices are perhaps too low. It is a statistical fact that finished steel prices stand at a much larger advance, in percentage, over pre-war averages than is the case with pig iron prices.

DEFLATION IN VALUES PROBABLE

Even steel prices are not as high, compared with pre-war averages, as are commodities in general. It is far from certain, moreover, that a general deflation in values is in prospect for the near future. Although European countries have very high exchange rates upon the United States, our foreign commerce is so aligned as to tend to produce or support inflation in this country, our merchandise trade balance being heavily in our favor, although whether this common expression to represent an excess of exports is really appropriate may be questioned. It is not certain that a large excess of exports at this time is really favorable to our economic situation.

For several weeks the steel mills have been rather indisposed to accept orders from other than regular customers. There are exceptions, but this has been the common attitude. On account of the disposition to refuse orders except from regular customers, the demand that has existed has appeared quite insistent and seems to be of larger volume than is really the case. As a matter of fact jobbers and manufacturing consumers are fairly well covered by contract to the end of the year.

Construction work involving the employment of steel shows a distinctly lagging tendency. New projects are not

being undertaken at this time in expected volume. Investors evince a decided tendency to hesitate in the matter of engaging in large undertakings, and the common view is that the hesitancy is due to uncertainties as to the labor cost of construction work involving a long period for its completion, as well as uncertainty as to the time when the work would be completed and would begin to yield returns. For several months following the armistice the common appraisal was that investors would not take hold until the cost of construction material should come down. That is hardly the theory now, since it is generally admitted that there will be no large declines in the near future, but labor costs are on an average quite as important as material costs.

In view of the employment of steel in construction work being well below the normal for active times, and in view of the fact that scarcely any steel is passing to the railroads, the employment of the steel industry, running as it is at about 80 per cent of capacity, is remarkably large. Exports are absorbing only about 20 per cent of the current output, so that the current everyday consumption of steel in domestic trade is really very large.

The Chemical Market

New York, September 10, 1919.

The past two weeks have brought forth a new interest in heavy chemicals in the nature of price inquiries by consumers looking to the fall buying of supplies, with an equally pressing inquiry for deliveries over 1920. Following these inquiries fair sized contracts have been signed covering delivery during the coming year. But this tendency to contract is not confined to heavy chemicals alone. An appreciable volume of business on the leading coal tar intermediates has been contracted for next year. Slashing of prices on many of the vegetable oils, heavy buying of crude rubber by leading tire manufacturers, as well as by dealers last week, with a very dull market on both waxes and naval stores sum up the latest developments.

HEAVY CHEMICALS

Deliveries on existing contracts make up the bulk of present activity in industrial chemicals. Manufacturers are so busy that ten days is the best delivery possible on new orders. Stocks in second hands, too, appear to be less plentiful.

All manufacturers are behind in the production of *sodium bichromate* and do not expect to be caught up until January 1. Their quotations are 15-16c. per lb., sales being made only to old customers. At the last writing, when demand was less active, 14c was the minimum offered by dealers, but at present they are quoting firmly at 14½-15c. The demand is not only foreign, but emanates from the tanners as well.

Bleaching powder (calcium hypochlorite) is one of the products for which contracts have been signed, Buenos Aires being a heavy buyer in the foreign field. The price has been raised to \$2.25 per cwt. by some dealers, others announcing no change.

Caustic soda (sodium hydroxide) is active with England offering some lively competition. The price on contract for 1920 is given as \$2.82 per cwt., for 60 per cent, f.o.b. works.

Among the chemicals on which the shortage is especially felt are *sodium sulphide*, *muratic (hydrochloric) acid*, *Glauber's salt*, *soda ash*, *potassium prussiate*, *yellow*, and *glacial acetic acid*. But despite this condition there have been no alterations in price. One large producer who is unable to accept new business in muriatic acid, asserts that if he were in a position to spare any of his output it could be readily marketed at \$1.75 per cwt. in tank cars, as compared with the previous maximum figure of \$1.50. The scarcity of *potassium prussiate*, *yellow*, is readily accounted for by the fact that manufacturers, finding its production unremunerative, have ceased to make it until the price attains a stable basis.

During the past week *formaldehyde* was moved up by several dealers to 22½c. per lb. from 19-21c. Probably the lowest figure at which it can be bought is 20½c. Back of the advance is the paucity of stocks and the sold-up condi-

tion of manufacturers as well as the firm position of wood alcohol.

Obviously with the object of reducing competition in second hands, domestic manufacturers of *tartaric acid* have announced a reduction of approximately 7c per lb., thus establishing the market for crystals and powdered at 79½c. This sharp cut was primarily made possible because of the improvement in the raw material situation.

On Sept. 2 a new schedule of prices for refined sulphur was announced, according to which sulphur flowers is quoted at \$3.10 per cwt. in carlots and sulphur, roll, at \$2.95.

Aluminum sulphate and salt cake (sodium sulphate) conclude the list of particularly active chemicals. With paper mills running to capacity, they are pressing for shipments of the former. Salt cake is well sold up for domestic use, while inquiries are coming from Norway, Sweden, Finland and Canada. But owing to the lack of an international medium of exchange between Scandinavia and United States, England is in a better position to handle this demand, while American producers must underquote England to place orders in Canada.

OILS

The present dullness and sharp cut in prices of vegetable oils can be attributed to three facts: the Government movement to reduce prices, the adverse exchange situation and the failure of European demand. The stoppage of buying from Europe is, of course, almost entirely due to exchange, for fats and oils are needed there as urgently as ever.

Dealers believe that the present condition is merely transient and that prices will begin to creep back, especially when domestic consumers realize that stocks are not large. The majority of oils are selling on an average of at least a cent under last market quotations. The weak condition of the local linseed oil market is evinced by a drop of 10c on September oil, to \$2.12 per gal. for raw oil in carlots. Some, however, hold to the old level of \$2.22 for spot delivery. October-November delivery is held at \$1.98 per gal., December-January at \$1.93.

Fish oils are sharing in the downward trend, winter pressed Menhaden now being quoted at \$1.32 per gal., a decrease of 3c.

COAL TAR PRODUCTS

Reflecting the recent boom and heavy trading in coal tar intermediates, as well as the augmenting price of raw materials, several price advances are announced. Aniline oil still retains the spotlight of interest. If it was scarce two weeks ago its present status can easily be inferred from the fact that the output of a leading producer is sold from thirty to forty-five days in advance. Whereas a fortnight ago it could be bought at 26c. per lb. little is now obtainable at 30c., manufacturers' prices ranging anywhere from 30-33c.

Along with aniline oil, aniline salt is a scarce item. Although at this writing no advance in price has been made, if demand continues with the present impetus, an increase is likely.

Both salol and salicylic acid have increased in market value by 5c per lb. which fixes the inside figure of the former at 85c and that of the latter at 45c.

Along with the advances in prices is not to be overlooked the encouraging tendency to contract. As a result a fair volume of future business has been closed for aniline oil, beta-naphthol and dimethylaniline, which products, excepting beta-naphthol, are being bought in quantities by Japan and Mexico.

Varying from the general tendency in the coal tar field, competition has brought benzoic acid to 90c per lb. from the previous quotation of \$1.00-\$1.10.

Now that the sale of Government phenol has been settled, with the Monsanto Chemical Co. acting as the sole selling agent, stocks are being offered at 12-15c per lb. works according to quantity and quality, and subject to certain restrictions. As yet sales cannot be made for export although there is a good demand.

CRUDE RUBBER

Initiating a departure from the continued tranquility in the crude rubber market, plantation grades developed unusual strength last week, all grades being advanced approximately 5c. per lb. Some large orders for October-December and January-June delivery were placed by leading tire manufacturers, who have been holding out of the market. Dealers kept up their end of the activity by purchasing heavily.

Although buying has slowed down perceptibly during the present week, firm foreign markets taken in conjunction with the fact that futures are still quoted above spot (a reversal of normal conditions) presage a firm market with higher prices.

NAVAL STORES

The demand for pine oil, which is at present said to be larger than can be supplied, is not to be taken as an indication of the state of affairs among naval stores. Last week when some activity was in evidence spirits of turpentine suddenly jumped to \$1.91 per gal. It has rapidly declined until the present finds it at \$1.63. This instability of turpentine has led to the substitution, wherever possible, of the lower priced pine oil. Pine oil, steam distilled, holds at \$1.05 per gal.

Chicago, September 10, 1919.

Settled prices and a rather quiet market are the rule in all lines in the Chicago district. Buying continues sufficiently active to sustain prices at existing levels, which in many instances seem high, but is apparently confined to current needs, no one caring to take a chance and lay in surplus stock at prevailing costs. Export business remains negligible, and will probably remain so while foreign exchange rates are so unfavorable.

Heavy Chemicals: Quotations made months ago, viz: Caustic soda, solid, 3½c. granulated, 4c.; soda ash, 2c., and bleaching powder (calcium hypochlorite), 2c., still hold good with demand steady and supply ample. Short supplies keep prices of red and yellow potassium prussiate and sodium bichromate up to the high points reached six weeks ago. With the exception of nitric, the acids show no change. 60 deg and 66 deg. sulphuric acid are quoted at \$12 and \$18 respectively, with fair demand for the lower grade. 18 deg. muriatic stands at \$22, but nitric, under weak demand, has fallen off to 9c. for spot delivery. Some export business has been handled on methyl alcohol but quotation stands at about \$1.25.

Coal Tar Products: The items in this line show undoubted strength. Toluol and benzol at 26c. and 25c. respectively are firmly held and aniline oil in drums advanced 3c. last week, now being quoted at 29c., with spot stocks exhausted and none offered for future delivery before November. Aniline salts have shared in this advance and now are 35c. for immediate delivery. Heavy demand for these commodities from local industries has created a shortage which it will apparently take some time to overcome.

Vegetable Oils: Over-inflation of prices some weeks is evidenced by the continued slump at present. Even linseed oil, under good and wide-spread demand, has declined five cents, \$2.13 being asked for large lots, \$2.37 for less than five barrels. Current quotations are: corn oil, 21c.; soya bean oil, 17c.; coconut oil, 21c., and cottonseed oil, 30c.

Flotation Oils, Naval Stores: A slight reaction has occurred, all grades of rosin being, at present, off about 50c. compared with thirty days ago. Today's quotation on W. W. grade is \$24 and on F grade, \$21. Turpentine is obtainable in limited quantities at \$1.73, having recently had a decline of 15c. followed by a quick recovery. Prices on distilled pine oil and pine tar oil show but one or two cents decline.

That pine tar products should have weakened at all is rather surprising, but is accounted for by the fact that many small producers of crude, tempted by prevailing high prices, have placed their entire stocks on the market. If this explanation is correct, some further slight decreases may be anticipated, but are almost certain to be followed by a market as strong, or even stronger than that of a few weeks ago. It is a fact that production has not equaled the season's demand, high prices being, therefore, inevitable.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, SEPT. 10, 1919

Michigan

DETROIT—The National Oxygen Co., 176 Oakland Ave., is having plans prepared for the construction of a 1-story, 40 x 122-ft. oxygen factory. Estimated cost, \$10,000. Brown & Preston, 406 Empire Bldg., architects.

DETROIT—The Monarch Foundry Co., Greenwood Ave. and Grand Trunk Ry., is having plans prepared for the construction of a 1-story, 100 x 200-ft. gray iron foundry on Herrick St. and Vernor Ave. H. M. Lane Co., Owen Bldg., engineers.

MINNETONKA—R. C. Brown, Metropolitan Life Bldg., Minneapolis, Minn., has awarded the contract for the construction of several reinforced-concrete and steel paper mill buildings, to Siems, Helmers & Schaffner, foot of Market St., St. Paul, Minn. Estimated cost, \$250,000.

Minnesota

FOLEY—The village will soon award the contract for the construction of a sewerage system to include a disposal plant. Estimated cost, \$13,400. Heury Bettendorf, clerk.

Missouri

ST. LOUIS—The Lowell Bleachery Co., 7718 Polk St., has awarded the contract for the construction of a 2-story, 102 x 105-ft. addition to its plant, to the Sutherland Building & Construction Co., 915 Olive St. Estimated cost, \$50,000.

ST. LOUIS—The Seuling Co., 6700 Manchester Rd., will soon receive bids for the construction of a 2-story steel rolling mill at 1835 Knox St. Estimated cost, \$30,000.

ST. LOUIS—The St. Louis Brass Manufacturing Co., Washington and Jefferson Aves., is having plans prepared for the construction of a 6-story, 175 x 300-ft. brass manufacturing plant on Washington Ave. Estimated cost, \$500,000. E. S. Guth, president.

ST. LOUIS—The St. Louis Independent Packing Co., 3315 Chouteau Ave., has awarded the contract for the construction of a 4-story, 100 x 150-ft. by-product manufacturing plant on Vandeventer and Chouteau Aves., to A. H. Haeseler & Co., C. Co., Wainwright Bldg. Estimated cost, \$55,000. The company is in the market for pulverizers and other equipment.

Montana

BUTTE—The State Board of Examiners, Helena, will soon award the contract for the construction of a 2-story, 75 x 125-ft. metallurgical building, for the State School of Mines here. Estimated cost, \$200,000. Floyd Hamill, 409 Lewisohn Bldg., architect. Noted May 15.

SHELBY—The city has awarded the contract for the construction of a sewage disposal plant, to the firm of Mirac Concrete Co., 437 Ford Bldg., Great Falls, at \$10,450.

Nebraska

BROKEN BOW—F. M. Skillman, city clerk, will receive bids until Sept. 23 for the construction of a sewerage system, including disposal in city and septic tanks. Estimated cost, \$105,000. Grant, Fulton & Letton, 505 Bankers Life Bldg., Lincoln, engineers.

GIBBON—The Gibbon Roller Mill Co. has awarded the contract for the construction of a 3-story, 106 x 120-ft. mill, to the Schrack Construction & Engineering Co., 412 American Bank Bldg., Kansas City, Mo. Estimated cost, \$55,000.

OMAHA—John Latener & Sons, 632 Bee Bldg., will receive bids Sept. 29 for the construction of a 6-story, 106 x 120-ft. hospital on 26th St. and Lawrence Ave., to include filters and a water softener, etc., for the Lister Hospital, 14th St. and Capital Ave. Dr. E. C. Henry, in charge. Total estimated cost, \$300,000.

New Jersey

HACKENSACK—The Hackensack Improvement Commission received bids for the construction of a sewage disposal plant, from Hauser & McIsaac, 18 East 41st St., \$774,402; Simpson & Brown, 90 West St., \$744,176, both contractors of New York City.

NEWARK—The Atlantic Smelting & Refining Co., Ave. R., has awarded the contract for the erection of plant, to Linde & Griffith, foot 4th Ave. Estimated cost, \$100,000.

NEWARK—The Coconut Oil Co. has awarded the contract for the construction of a 3-story factory, to J. Lowery, Jr., 108 West 40th St., New York City. Estimated cost, \$150,000. Timmis & Chapin, 315 5th Ave., New York City, architects.

NEWARK—The Presto-O-Lite Co., 786 Frelinghuysen Ave., has awarded the contract for the construction of 8 buildings, the largest measuring 60 x 400 ft. and the smallest 30 x 40 ft., for the manufacture of storage batteries for automobiles, oxyacetylene welding apparatus, etc. Mitchell, Inc., 76 Montgomery St., Jersey City.

New Mexico

HANOVER—The Republic Mining & Milling Co. plans to construct a steam turbo generator power plant, ball mill and flotation plant at its zinc mine here and is in the market for hoist, electrical equipment, crushers, flotation machines, etc. Estimated cost, \$100,000. C. W. Wiser, manager.

LORDSBURG—The Bonney Consolidated Copper Co., Grant Co., plans to construct a complete concentration and flotation mill to have a daily capacity of 100 tons. The company is in the market for compressors, etc. J. P. Fortens, superintendent.

SANTA RITA—The Grant County Copper Co. plans to install a flotation plant, etc., in its zinc mine here and is in the market for crushers, rollers, tables and vanners. Estimated cost, \$20,000. H. B. Link, superintendent.

New York

ALBANY—The Albany Perforated Wrapping Paper Co., 1271 Broadway, has awarded the contract for the construction of a brick addition to its factory, to William G. Sheehan Construction Co., 28-30 De Witt St. Estimated cost, \$18,000.

NIAGARA FALLS—The Carborundum Co., Buffalo Ave. and 14th St., plans to build a 3-story 99 x 224-ft. carborundum plant on Buffalo Ave. Estimated cost, \$150,000. L. J. Call, chief engineer.

ROCHESTER—The Board of Contract & Supply has awarded the contract for the construction of a new sewage disposal plant in the 23rd Ward, to Whitmore, Rauber & Vicinus, 279 South Ave. Estimated cost, \$49,927. Noted Feb. 15.

North Carolina

GOLDSBORO—The Seminole Phosphate Co. has awarded the contract for the construction of a 1-story fertilizer factory, to D. J. Rose, Rocky Mount. Estimated cost, \$22,000.

North Dakota

MINOT—The city plans an election Sept. 29 to vote on \$280,000 bonds for the construction of an intake to the sewer mains. E. J. Thomas, Minot, engineer.

Ohio

ASHLAND—The Faultless Rubber Co. has awarded the contract for the construction of a 3-story, 83 x 168-ft. factory addition here, to J. R. Gloyd Co., 1816 East 33rd St., Cleveland. Estimated cost, \$100,900. Noted Aug. 1.

CLEVELAND—The Enamel Products Co., 341 Eddy Rd., has awarded the contract for the construction of a 2-story, 40 x 180-ft. factory addition, to William Dunbar & Co., 8201 Cedar, Cleveland. Estimated cost, \$10,000. Noted Sept. 1.

CLEVELAND—The General Bronze & Foundry Co., 4300 Hamilton Ave., plans to construct a 1-story, 100 x 125-ft. factory on East 43rd St. Estimated cost, \$60,000. Architect not selected.

CLEVELAND—The Glidden Varulsh Co., West 10th St. and Berea Rd., has awarded the contract for the construction of a 2-story, 58 x 117 ft. factory addition at 11,410 Berea Rd., to J. R. Gloyd Co., 1816 East 33rd St. Estimated cost, \$15,000.

CLEVELAND—The Standard Brass & Foundry Co., 93 East 4th St., has awarded the contract for the construction of a 2-story, 38 x 59-ft. office and shop to August Haase, 9028 St. Claire Ave. Estimated cost, \$10,000.

CLEVELAND—The Superior Brick Co., Leader News Bldg., plans to construct a 2-story plant for the manufacture of bricks on Jennings Rd. Estimated cost, \$50,000. Architect not selected.

Oklahoma

COLLINSVILLE—The city voted \$40,000 bonds for the construction of a water filtration plant. Noted Sept. 1.

Oregon

BAKER—The Ben Harrison Mines Co. plans to enlarge its mining plant in Greenhorn District, also install flotation system and build machinery houses. Estimated cost, \$50,000. W. C. Fellows, Baker, manager.

FORTLAND—The Central Waxed Paper Co., 5600 Fillmore St., Chicago, plans to construct a 3-story plant in North Portland. Estimated cost, \$100,000. A. Christ, president.

Pennsylvania

LOCK HAVEN—The American Aniline Chemical Co. is making extensive improvements and additions to its plant which was recently operated by the Stanley Aniline Chemical Co. C. H. Dasher, manager.

NEW BRIGHTON—The New Brighton Board of Education is receiving bids for the construction of a 3-story, 90 x 135-ft. and 2-story, 82 x 98-ft. high school on Pierce and East 4th Sts. A chemical laboratory will be installed in same. W. G. Echles, New Castle, architect.

PITTSBURGH—W. W. Lawrence & Co., West Carson St., has awarded the contract for the construction of a paint factory, to E. A. Wehr, Highland Bldg. Estimated cost, \$12,500.

Rhode Island

PROVIDENCE—The Revere Rubber Co., 355 Valley St., has awarded the contract for the construction of a 30 x 121-ft. factory addition on Eagle St., to Cruise & Smiley Construction Co., Main St., Pawtucket. Estimated cost, \$20,000.

Texas

FORT WORTH—The Ok-In Producing & Refining Co. plans to construct a refinery having an ultimate capacity of 5,000 bbl. of crude oil per day. Work will be done under supervision of John S. Blair, chief engineer, and J. T. Thompson, superintendent of construction.

Washington

BOSSBURG—The Big Bonanza Mine plans to expend \$15,000 in development work and blocking out ore and installing concentrator. Olaus Jeldness, 2029 Second Ave., Spokane, manager.

NESPELEM—The Great Metals Mining & Milling Co. plans to improve its mill and is in the market for a filter press, clearing cells and storage bins. Elmer C. Williamson, manager.

SEATTLE—The Western Wall Board Co. plans to construct a 2-story, 50 x 100-ft. addition to its present plant at 4511 9th Ave., S. Estimated cost, \$20,000.

West Virginia

FAIRMONT—The West Virginia Metal Products Co. will soon receive bids for the construction of a 1-story, 230 x 360-ft. factory, J. M. Boyle, 14 Wall St., New York City, engineer.

HUNTINGTON—C. C. Haywood and others, Ironton, Ohio, plan to build a plant for the production of bricks on 16th St. Rd. Estimated cost, \$200,000.

HUNTINGTON—The Huntington Tumbler Co. plans to construct a 1-story, 82 x 275-ft. glass manufacturing plant on 15th St. Estimated cost, \$100,000. A. Ford Dickey, architect.

HUNTINGTON—The Huntington Brick & Tile Co. plans to construct a 1-story brick plant at Westmoreland, to include elevators, main building, 100 x 150 ft., also an 80 x 100-ft. dry kiln and 16 oval top kilns of 50-ft. diameter. Estimated cost, \$150,000. T. M. Davidson, engineer.

British Columbia

BURNABY—The Gregory Tire & Rubber Co., 1404 Standard Bank Bldg., Vancouver, plans to build a 1-story, 100 x 240-ft. mill construction factory on Euclid Ave. and Collingwood St., here. Estimated cost, \$50,000.

Ontario

BIRCHCLIFFE—Scarboro township plans to construct a waterworks system, to include filters, intake, etc. Estimated cost, \$100,000. E. James, 57 Adelaide St., E., Toronto, engineer.

BROCKVILLE—The Consolidated Iron & Steel Corp., Ltd., 20 King St., E., Toronto, plans to construct an iron smelter, here. Estimated cost, \$8,000,000.

CAPREOL—The Canadian National Ry., 27 Wellington St., E., Toronto, plans to install a chlorine or ultra violet sterilization system for swimming pool in connection with proposed 3-story, 72 x 120-ft. Y. M. C. building, which it plans to construct. Total estimated cost, \$75,000. A. F. Stewart, 27 Wellington St., E., Toronto, engineer.

TORONTO—H. B. Johnstone & Son, 714 Dundas St., E., will soon receive bids for the construction of a 3-story, 80 x 150-ft. tannery on Cameron Ave. Estimated cost, \$130,000. John M. Lyle, Avondale Rd., architect.

Quebec

MONTREAL—The Booth Coulter Copper & Brass Co., 19 Queen St., has awarded the contract for the construction of a 2-story, 25 x 40-ft. factory, to S. Saratinal, 470 Amherst St. Estimated cost, \$19,000.

Hawaii

HONOLULU—The Hawaiian Fertilizer Co. is having plans prepared for the construction of a 3-story, 60 x 130-ft. factory, P. Romberger, Crocker Bldg., San Francisco, Cal., engineer.

Coming Meetings and Events

THE AMERICAN CERAMIC SOCIETY will hold a meeting in Chicago, Sept. 24.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its Fall meeting in Chicago, Sept. 23 to 25 inclusive.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1919 convention in Philadelphia, Sept. 29 to Oct. 4.

THE AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition of gas appliances and apparatus at the Hotel Pennsylvania, New York, Oct. 13 to 18.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its Fall meeting in Chicago, Ill., Sept. 22 to 27.

THE AMERICAN PEAT SOCIETY will hold its thirteenth annual meeting at Minneapolis, Minn., Sept. 22 to 24 inclusive.

THE AMERICAN STEEL TRAILERS' SOCIETY will hold its first annual convention in Chicago, Ill., Sept. 22 to 27.

THE ELECTRIC FURNACE ASSOCIATION will hold a meeting in Chicago on Monday, Sept. 22.

THE ELECTRICAL EXPOSITION will be held in Grand Central Palace, New York City, Sept. 24 to Oct. 4.

THE FIFTH NATIONAL EXPOSITION OF

CHEMICAL INDUSTRIES will be held in Chicago, Ill., Sept. 22 to 27 inclusive.

THE INSTITUTE OF METALS DIVISION of the A. I. M. E. will hold its next meeting in Philadelphia, Pa., Sept. 29 to Oct. 4.

THE NATIONAL SAFETY COUNCIL will hold its Eighth Annual Safety Congress in Cleveland, Oct. 1 to 4.

THE TECHNICAL ASSOCIATION OF THE IRON AND PAPER INDUSTRY will hold its Fall meeting in Chicago from Sept. 24 to 27.

Industrial Notes

CAPT. DONALD M. LIBBELL, through whom on July 21 he again took up his work in chemical engineering with offices in Rooms 1800-1802, 66 Broadway, New York City, and a laboratory at 961-965 Frelinghuysen Ave., Newark, N. J.

THE WHEELER & ENGINEERING Co., Carter, N. J., elected Mr. J. J. Brown, formerly vice-president and general manager, as president, at its board of directors meeting July 8. Mr. J. J. Brown succeeds Charles W. Wheeler, recently deceased. Mr. H. S. Brown, of Congress St., Boston, was elected vice-president.

THE HERCULES ENGINEERING CORP., of Chicago and New York, announces that Major M. G. Donk has joined its staff. His work is of a special character on the installation of equipment.

Mr. J. T. Brewster, who has acted in a consulting capacity with this corporation for the last three years, succeeds Mr. A. H. Alberger as head of the technical and engineering department.

BRIGGS & TURVAS, of Chicago and New York, operators in iron and steel scrap and salvage, have purchased from the Imperial Munitions Board of Canada the entire plant and property of British Chemical Co., Ltd., located at Trenton, Province of Ontario, Canada. A Canadian corporation under the name of Briggs & Turvas of Canada, Ltd., and capitalized at \$1,200,000 has been formed, with main offices in the C. P. R. Bldg. at Toronto, Ontario, and a branch office at Trenton, Ontario. The property consists of 255 acres and fronts the Trenton River, a navigable stream, with Lake Ontario as its source. Three trunk line railroads enter the plant. The British Chemical Company was formed and built during the war at an outlay of approximately \$8,000,000. It is completely modern in all respects. The equipment consists principally of two separate and complete sulphuric acid plants, one sulphuric acid concentrators, a nitric acid plant, an alcohol rectifying plant, two refrigerating plants, a smokeless powder plant, a complete high pressure fire system, a complete set of narrow gauge electric locomotives and trucks, two boiler houses, electrical equipment, warehouses, storage tanks, administration buildings, etc. The plant has a capacity of over 100 tons of sulphuric acid, 75 tons of nitric acid, 25 tons of finished smokeless powder and 45 tons of ethyl alcohol. The new owners are as yet undecided as to the extent of the operations of the plant for the future, but it is expected that the powder manufacturing apparatus and equipment, and possibly the nitric acid plant, will be dismantled and disposed of, allowing the sulphuric acid plants to stand, there being a good market in Canada for sulphuric acid for the manufacture of fertilizer, for which the demand in this country is great.

THE FATE-ROOT-LEATH CO. announces that on July 1, 1919, it succeeded to the business of the J. D. Fate Co. and the Root-Heath Mfg. Co., the consolidation being made at a meeting of the directors at Plymouth industrial locomotives, clay-working machinery and other Plymouth products. The officers of the new company are: President, J. A. Root, vice-president and general manager, C. E. Heath, second vice-president, W. F. Root, secretary, P. H. Root, treasurer, H. R. Sykes, and sales manager, H. J. Votan.

THE WORTHINGTON PUMP & MACHINERY CORP., New York, announces its purchase of the plant, patents, accounts, patents and other assets of the Epping-Carpenter Pump Co., located at 10 43rd St., Pittsburgh, Pa., which will be known as Epping-Carpenter Works of the Worthington Pump & Machinery Corp. Orders and contracts now in hand will be completed by the Worthington Pump & Machinery Corp., and all further business will be for its account.

BECKMAN & FRITCHARD, Inc., announces that a postoffice has been established at

Mineral City, Fla., and requests that all communications be sent there with the exception of telegrams, which should be sent to Pablo Beach, Fla.

THE BRONZE ALUMINA CORP. has removed from Tonawanda, N. Y., to a new shop in Buffalo.

THE ELECTROLYTIC OXY-HYDROGEN LABORATORIES, INC., has formed a new company to sell and manufacture company under the name of the Electrolytic Company. The Electrolytic Oxy-Hydrogen Laboratories, Inc., will continue in charge of the laboratories and maintain a technical supervision over the work of the new company. The general offices and works of both companies have been moved from Dayton, Ohio, into larger quarters at 2635 Ponce Avenue, Pittsburgh, Pa., to provide increased facilities for its expanded business. The general sales offices are being continued at 15 William St., New York City, and branch sales offices have been opened in the Morris Bldg., Philadelphia, and the Merchants Exchange Bldg., San Francisco. Mr. I. H. Levin continues in charge of technical and laboratory research work, and Mr. D. J. Tonkonogy in general charge of sales.

THE LIVINGSTON REFINERS CORP. of Tulsa, Okla., has just placed an order for 100 Henry Ward cars with the Pennsylvania Tank Car Co. of Sharon, Pa., to be used in the transportation of the corporation's petroleum products.

THE GREEN ENGINEERING CO., East Chicago, Ind., has been appointed to represent the firm of Bull & Livensperger as its sales representatives in Chicago and northern Illinois territory. On Aug. 1 they took possession of the Chicago sales office at 14 E. Jackson Blvd. The company also announces the appointment of Mr. E. L. Sullivan as representative in the Pittsburgh district.

MR. WILLIAM LANTON announces that he has sold the plant of the ROBERT LANTON ZINC & ACID CO., at Hillsboro, Ill., to the Eagle-Picher Lead Co.

THE BLAW-KNOX CO., Pittsburgh, Pa., announces the appointment of Mr. L. C. Murray as general salesmen in the "Knox" department. This company also announces the opening of an office in the Little Bldg., Boston, Mass., and in the Owen Bldg., Detroit, Mich. Mr. A. W. Ransom will have charge of the New England office, and Mr. H. J. Desson will be manager of the Michigan district.

THE CHICAGO PNEUMATIC TOOL CO. plans making its general office in Chicago, New York, and is erecting an office building at 6-8 East 44th Street, New York City. This company also announces the removal of its Cincinnati office from the Mercantile Library Bldg. to the Little Bldg., the appointment of Mr. J. L. Canby as district manager of sales at Chicago, succeeding Mr. Nelson. Mr. Canby, who has been transferred to New York as district manager of sales; and the appointment of Mr. Fred Gelbauer as special Navy Yard representative, with headquarters at the Philadelphia office.

THE FOUNDATION CO., New York City, announces that at a recent meeting of the board of directors, Franklin Remington was elected chairman of the board, John W. Doty was elected president of the company, and H. J. Deutschbein first vice-president and general manager.

CHAS. BUTTERS & CO., LTD., New York, announces that Mr. Chas. Butters, who has hitherto been acting as managing director, is no longer associated with the company.

THE NATIONAL ASSOCIATION OF PURCHASING AGENTS through its standardization committee is endeavoring to bring about the adoption of standard forms for invoices, purchase orders, acknowledgments and notices of shipment. Any one interested in this movement should communicate with the chairman of the committee, Mr. W. L. Chandler, Dodge Sales & Engineering Co., Mishawaka, Ind.

THE ELECTRIC FURNACE CONSTRUCTION CO., Philadelphia, advises the receipt of an order from the Hammond Steel Co., Syracuse, N. Y., for one 3-ton furnace for the manufacture of high-grade tool steels; the installation of a "Greaves-Etchells" furnace in the Hongkong Steel Foundry Co., China; an order from the Central Telegraph member of the Brazilian Military Commission, through Fenwick Freres & Co., New York, for a "Greaves-Etchells" electric furnace; an order for a new electric furnace castings plant, the Dodge Steel Co., Philadelphia, which installation will be a 3-ton furnace of the latest "Greaves-Etchells" type.

THE CASSEL CYANIDE CO., of Glasgow, will incorporate a subsidiary company in Canada.

New Publications

THE ANNUAL REPORT on the Mineral Production of Canada, During the Calendar Year 1917. Issued by the Canadian Department of Mines, Ottawa.

THE CARBONIZATION OF MISSOURI CANNELOPES. Leaflet No. 10, 1918, compiled and by Karl Kenneth Kershner and Vivian Xly Smiley. Vol. 5, No. 1, of the technical series issued by the School of Mines and Metallurgy, University of Missouri, Rolla, Mo.

A REFERENCE LIST OF THE ELECTROCHEMICAL INDUSTRY is the title of a copyrighted pamphlet issued by the American Electrochemical Society, South Bethlehem, Pa. This pamphlet contains a comprehensive list of firms engaged in this industry in the United States and Canada and also gives a list of the products of the industry.

THE SENSITIVENESS OF SOME CYANIDE REACTIONS. By John B. Ekeley and Icie C. Macy. Published by the Colorado Scientific Society, Denver, June, 1919.

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY and IRON & STEEL MAGAZINE

Volume 21

New York, October 1, 1919

Number 7

Announcement of Weekly Publication

BEGINNING with this issue of CHEMICAL & METALLURGICAL ENGINEERING, the magazine will be published weekly instead of semi-monthly as heretofore. The project has been under consideration for more than a year, and only unusual industrial conditions throughout the world prevented the consummation of the plan at an earlier date. We believe the step is now justified by the situation prevailing in the industries represented in our title. Not only are they more firmly established than ever before in the history of our country, but they are more vital to our eminence as a world power. There is international competition ahead not yet realized, nor will it manifest itself in full measure until the nations of Europe settle down to steady production and strike their gait. It were nothing short of the folly of unpreparedness to await that time before putting our own house in order. Progress is rapid; developments grow apace; the industries are in a state of flux. Prompt and timely presentation of the news, technical and industrial, demands more frequent publication of a magazine that presumes to act as an exponent of chemical and metallurgical engineering in the United States. In this effort to serve new as well as old established industries within their domain, American publishers are not alone. Contemporaries have recently made their appearance in England and Canada; German publishers are again active, and French technical literature is appearing in greater quantity than ever before. The need of disseminating information while it is timely and valuable is felt throughout the world. We are confident, however, that with the co-operation of our readers and contributors we can so serve our industries as to keep them not only abreast of the times but in the van of progress. To this end we have laid our plans, and to its accomplishment we pledge unlimited facilities.

The Path Of Sanity

BLASÉ indeed must be the man who can view with equanimity and unconcern the threatening aspect of the industrial situation in the United States today. With radical agitators defying their more conservative superiors, with labor unrest lowering production at a time when steady and greater production is one of the remedies of our trouble, with inflammatory speech and action prevailing where wise counsel and sober meditation was to have been expected, and with men by the hundred forsaking the paths of reason and sanity to follow after false gods, the need of wise leadership was never greater. A task is set for every patriotic Ameri-

can who cares to see his country escape the catastrophe that has engulfed Europe, particularly Russia and Hungary. We hold it to be the duty of every intelligent citizen to exert his influence for patience and reason, to speak wisely and inculcate sound doctrine among his associates, to discountenance violence, threats and incendiary speech, and to get clearly in his own mind the fundamental elements of the situation.

No man of vision doubts that the world is undergoing a profound change in the social order that means as much for democracy in industrial relations as the war did for democracy in government. The evidences are on every hand and found in the mouths of true leaders of Capital as well as of Labor. But it is a change that is not going to be wrought by force and violence; nor does it need to be, because the truth is appreciated by those who have the power to put it into effect. It may have been necessary for Russia to have her experience in Bolshevism, but, as Mr. HOOVER says, "it is not necessary that we of the United States, now that we have witnessed these results, plunge our own population into these miseries and into a laboratory for experiment in foreign social disease."

It is, however, necessary that we should find the proper remedy, not only for the foreign social disease but for the domestic malaise that now afflicts us and offers a tempting excuse for the agitator. Mr. HOOVER believes that this is "the paramount business of every American today," and that "we shall never remedy justifiable discontent until we eradicate the misery which the ruthlessness of individualism has imposed upon a minority." This is a sufficiently strong statement to please even a radical agitator, but it emanates from an intelligent source and carries conviction that is lacking in the catch phrases of the Reds. Labor today has the sympathetic ear of an intelligent public. The pendulum has been swinging its way for some time past, even to the detriment of Capital, and we have made more than an approach to that equality of opportunity and better distribution of production which is the ideal condition. Undoubtedly both Labor and Capital have much more to learn, and the Community has something to demand of both. In the light of the present situation, what may these things be?

In the first place, Labor must appreciate the fallacy of reaching Elysium through constant reduction of hours of employment and increase in compensation. The demoralized industrial production of Europe, particularly those parts in which the experiments of Communism have been tried, must convince even the ignorant that only disaster can follow such steps. Two years of Bolshevism have plunged the Russian people into deeper physical distress than ever they knew under

the Czar; and today, as Mr. HOOVER points out, "the very High Priest of Socialism is vainly endeavoring to save his people from their destruction by summoning back the forces of production." Russia had raw materials and labor in plenty, but in some mysterious way all were to prosper without producing. As a consequence Mr. HOOVER believes that "Socialism as a philosophy of possible human application is bankrupt," having "wrecked itself on the rock of production."

A lesson may be taken by Labor from the new spirit of the German republic. If the cabled news is to be accepted, German labor believes that only in steady and increased production lies their salvation. Nay more, they believe that it is the road to national supremacy. Consequently, we find them demanding not shorter hours, but longer; not restricted production in order that more may be employed, but unlimited production so that the people as a whole may enjoy a higher standard of living and the workers receive a larger return. It may be stated as an accepted fact that the nation which most quickly resumes normal production will occupy the strategic position in world trade, and the sooner Labor realizes this and proceeds accordingly, the better for all of us.

With wider powers and increased authority in industrial affairs, Labor must accept a new responsibility. Its wiser leaders are deprecating the use of the strike, especially among classes of public servants on whom the safety of the community depends, but there are still many agitators who would have policemen, firemen and similar workers enforce their demands with the strike. This is little short of madness, for it is but a step further to involve soldiers and sailors—and then Soviet government. If Labor cannot intuitively perceive the duty and responsibility of public servants to the community, and discountenance the formation of striking unions among them, public approval must inevitably desert the Labor cause. The Governor of Massachusetts is worthy of all commendation for his action in the Boston police strike. More power to his arm, and to all who show his wisdom and courage!

If Labor has lessons of moderation and co-operation to learn, so has Capital. First it must take the initiative in bringing about that co-operation that must exist before either party can prosper in the highest degree. Labor's demands for a share in the profits and in the management of industry are generally recognized as fair, and it is incumbent on intelligent Capital and Management to devise equitable schemes for the consummation of these ideas. As Dr. STEINMETZ once said, "there are several ways—mostly unsuccessful"; but he went on to declare that "Capital is entitled to a fair rate of interest on the money invested and Labor is entitled to a fair rate of wages for the work done. All profits beyond that belong to Capital and Labor. These should be divided as dividends on capital stock, and on labor stock as found by yearly wages. This system is in operation in a number of corporations."

As intimated before, there must be a more equitable distribution of the products of industry, and this means the abolition of profiteering and of the exorbitant profits on capital that once were regarded as perfectly legitimate even though obtained at the expense of fair treatment of the workers. If Labor's right to share in the profits of industry is being recognized, no less is its right to share in the management. Capital must recognize the fact that domination by any one element will not secure maximum production, so essential to

the welfare of the Community, but that it will be obtained only by "giving a voice in the administration of production to all sections of the Community concerned in the specific problem."

All these ideas will seem idealistic to the conservative and reactionary, but they are in practical application in enough places and enough forms to know that they are fundamentally right and workable. The Community is demanding more and more that industrial conditions be established that shall relieve it of the periodical hold-up to which it is subjected by strikes and profiteering. We believe the most progressive minds of the day are confident of the future and willing to risk the application of principles of fairness and justice. We believe with LOWELL, who wrote

New times demand new measures and new men;
The world advances and in time outgrows
The laws that in our fathers' day were best;
And, doubtless, after us some purer scheme
Will be shaped out by wiser men than we,
Made wiser by the steady growth of truth.
The time is ripe, and rotten-ripe, for change;
Then let it come; I have no dread of what
Is called for by the instinct of mankind.
Nor think I that God's world would fall apart
Because we tear a parchment more or less;
Truth is eternal, but her effluence,
With endless change, is fitted to the hour;
Her mirror is turned forward, to reflect
The promise of the future, not the past.

Herbert C. Hoover— American Citizen

GREAT as was the professional part played by engineers during the war, to none of them was it given in such great measure as to Mr. HOOVER to direct the economic forces that were so vital to the success of the conflict; to no other private citizen of the United States was it given to emerge from five years of arduous labor as an outstanding world figure, known, respected and honored among the nations of the earth. Small wonder, then, that the American Institute of Mining and Metallurgical Engineers took advantage of the occasion of Mr. HOOVER's return to this country to do him honor, and at the same time bring the profession of engineering into the reflected light of his glory. His career and record are not only a refutation of the charge that engineers take slight interest in public affairs, but they exemplify the peculiar fitness and ability of the well-trained engineer for the administration of large public affairs.

It has not been uncommon for the average citizen to express surprise that HOOVER, the mining engineer, should have been so successful in the rôles he has undertaken and performed so well. That is because of an erroneous public impression of the nature and character of engineering. As was so pertinently pointed out by Mr. SAUNDERS in his introduction of Mr. HOOVER at the dinner, the modern definition of engineering is that lettered on the wall of the Engineering Societies' library in New York—"Engineering, the art of organizing and directing men, and controlling the forces and materials of nature for the benefit of the human race." In every detail Mr. HOOVER's work of the past five years has come within the scope of the definition; men in large numbers have been organized and directed, and the forces and materials of nature have been controlled for the benefit of the human race. The combination comprises engineering, and the man who has shown ability to compass the task has proved himself in the highest degree an engineer.

A brief account of the dinner in Mr. HOOVER'S honor, and his address on that occasion are printed elsewhere in this issue. We commend a careful reading of the latter because it presents the first-hand observations and the sound judgment of an intelligent student of world problems since the Armistice.

We deem it appropriate, in the interest of straight thinking among our people, to give it as wide publicity as possible.

Fifth National Exposition of Chemical Industries

THE Fifth National Exposition of Chemical Industries, which Chicago papers called the first, opened on the minute Monday, September 22. Lack of space in the Coliseum required that the First Regiment Armory also be engaged, making it like a train in two sections.

Praise is due both to the management and the exhibitors for being ready when the doors opened.

The exhibits while growing in scope are developing a popular side. Charts showing the steps of processes were much more generally displayed. There was also a greater amount of miniature apparatus, some of which was in operation, and it was very illuminating. It was not only instructive to the curious but showed clearly the scope and requirements of a plant or department to make a given product. A noteworthy feature was that the exhibitors had learned better how to exhibit and we shall comment on this in notes on the Exposition. On the whole it was the best show that has been held and we extend to the management our felicitations.

More Power to the Bureau of Mines!

A SIGNIFICANT milestone in the history of the Bureau of Mines was passed a few days ago with the dedication of its handsome new Pittsburgh laboratories, no less a monument to the broad vision of Dr. HOLMES, the first director, and his associates than to the constancy of purpose with which their successors have built upon this foundation. Any institution which starts on a serious campaign for the conservation of life and resources in any industry truly has an ever-widening field awaiting it.

When the Bureau was first proposed more than a little opposition arose from those who failed to see where a governmental department could effectively cooperate with the mining industry without assuming dictatorial powers so disagreeable to Americans. Few indeed are the critics now remaining. Time has shown how scientific investigation by an organization with no mandatory powers but properly officered can safeguard the life of the miner and smelterman, how this organization of specialists can investigate methods of treating refractory ores, methods of winning fuels from unusual sources, methods of proper utilization of our easily-mined supplies so as to involve minimum wastage before the product reaches the hands of the consumer.

More power to the Bureau of Mines! More funds for its important investigations! More research men of highest caliber to explore mining and metallurgical byways, and more competent engineers to interpret their discoveries to the industry!

May its future be as honorable and influential as its past.

The Steel Strike An Object Lesson

THE steel strike turns the pitiless light of publicity upon policies of labor agitators that have been growing more common and connects the most reprehensible practices with the organized labor that is sponsored by the American Federation of Labor and its head, SAMUEL GOMPERS, who has been referred to in many quarters as the second president of the United States.

Something, and something big, is going to come of this. The Senate has been investigating it. The White House conference on labor to be held October 6 cannot avoid considering it. The campaign to "organize" the iron and steel industry was initiated at the annual convention of the American Federation of Labor at St. Paul in June, 1918. The organization campaign was conducted under the auspices of 24 unions, affiliated with the A. F. of L., but when the strike call was persisted in at least one of those unions withdrew and ordered its locals not to participate.

The organization campaign was directed chiefly at common labor, and was successful only with ignorant foreign-born common labor. The strike committee approached Judge GARY, chairman of the Steel Corporation, for a "conference," was refused, and approached no other manufacturer. The strike call followed, for September 22, and the first two days of the strike threw idle about one-third the iron and steel producing capacity, almost wholly because foreign-born common labor struck while other labor was intimidated.

The issue was collective bargaining and the closed shop, bargaining with labor agitators who pretended to represent men because they had collected \$3 each from them, the "organizer" getting \$2 commission, one of the twelve points in the organization platform being the "check-off" whereby the collection of subsequent sums, \$3 or other amounts, would be made sure.

Surrender meant eventual relinquishment of practically all property rights, while no compromise ground was conceivable. The agitators might have been content with less than all at the outset, knowing that eventually they were certain to get all. The only questions therefore are of the time and hardships involved while the manufacturers win the strike and the influence these events will have upon the general labor situation. During the strike men willing to work will be prevented from working by intimidation. Consumers of steel will have their supplies curtailed, and as steel is used in almost all work, the whole country will be seriously inconvenienced. There are no stocks of steel that will help materially.

The American Federation of Labor can be held responsible for this effort to disturb a peaceful industry, on whose operation the welfare of the major part of the public is more or less dependent, to incite riot and bloodshed, for that is what it means in actual substance, and in fact to start a bolshevist revolution.

Here are two issues, the closed shop and the revolution. Mr. WILSON, years before he became President, declared himself to be "a fierce partisan" of the open shop. Let us hope he is so still. He will have much to do with conducting the deliberations of the coming White House conference on labor.

A New Compensated Heatmeter

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the Sept. 1 issue of CHEMICAL & METALLURGICAL ENGINEERING, a "New Compensated Heatmeter" is described by Mr. Charles P. Frey. It is the purpose of this note to call the attention of the author to the fact that the use of "heatmeter" for an instrument which is in no way used to measure quantities of heat is a misnomer and should be carefully avoided. The instrument described measures temperatures by measuring the current produced when the junction of two thermocouple wires is maintained at a temperature different from the temperature of the other ends which are joined either directly or indirectly to the instrument. The use of "heatmeter" for an instrument which indicates temperatures may not seem to some to be much of an error, but they should realize that such practice is the same as using the words "temperature" and "heat" synonymously. The proper use of these two words is one of the first things the high school boy is taught upon taking up his first introduction to the subject of heat in his elementary physics.

The author also states that an ammeter is substituted in place of a pyrometer. In fact the instrument, together with thermocouple, is only a pyrometer in which an ammeter is used to indicate the effect due to a thermo-electromotive force being maintained in a circuit instead of a potentiometer, galvanometer, etc.

If the Brown Instrument Co. wishes its instrument to make a favorable impression in the eyes of the public, it would be better to advertise it under one of the usual names or at least one that is not misleading.

War Department Deserts Chemical Warfare Service

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am enclosing herewith a copy of a letter by Prof. B. B. Freud of the Armour Institute of Technology, Chicago.¹ A copy of his original letter was sent to the Secretary of War and promptly routed through military channels to me for remark. I am also enclosing a copy of my remarks, which you are at liberty to use if you so desire.

AMOS A. FRIES,
Lt.-Col. C. W. S.

Edgewood Arsenal,
Edgewood, Md.

From: Commanding Officer, Edgewood Arsenal, Edgewood, Md.
To: Director, Chemical Warfare Service, Washington, D. C.
Subject: Accompanying correspondence of Capt. B. B. Freud.

1. Submitted herewith are my observations in regard to the attached letter from Prof. Freud to the Editor, CHEMICAL & METALLURGICAL ENGINEERING, a copy of which was forwarded to the Secretary of War.

2. Capt. Freud was commissioned a Captain, Chemical Warfare Service, without previous military experience or even training in gas warfare, on July 27, 1918. Less than a month later he sailed for France, where he was first assigned to the laboratory in Paris. The assignment was very shortly revoked and he was

sent to the gas school at Hanlon Field. He completed the courses there on Oct. 12, and thereafter, until the armistice, he was connected with gas experimentation at Hanlon Field. He was returned to the United States promptly when the war ended, receiving his discharge Dec. 24, 1918.

3. Capt. Freud thus had no field experience, nor did he serve long enough in France to get acquainted with the actual work of the Chemical Warfare Service. So far as known, Capt. Freud was never near the front line. He never got really acquainted with the activities of a Division gas officer, nor did he take any part whatever in the training or operations of gas troops. His case is one of the best examples that has ever come to my knowledge of the danger of "a little learning."

4. Taking in order the remarks of Capt. Freud, we find him first referring to gas masks. The best answer to his questions as to why the study of chemicals for gas masks should not be under chemists and physicists and why the production of finished masks should not be under the Ordnance Department is to ask why the study of diseases and their cure should not be under chemists and physicists and not under the Medical Department, or why the manufacture of medicines, surgical instruments and other implements used by the medical profession should not be under the Ordnance Department or the Corps of Engineers.

5. That sort of thing is exactly what was tried in chemical warfare, in the beginning of the war, and found to be an utter failure. When I was made Chief of the Gas Service in France the various activities now under the Chemical Warfare Service were subdivided among the Corps of Engineers, the Medical Department and the Ordnance Department, respectively, while for research and experiment it was necessary to deal directly with the Bureau of Mines in the United States. Before my assignment an officer of the Medical Department had been given broad powers under which to act on gas matters, and yet we were getting no masks, no training and no decision on gases to be used or shells or bombs in which to put them. Indeed we were getting no action on anything concerning chemical warfare in the field.

6. Everybody's business was nobody's business, as usual. No one had any special interest in chemical warfare or incentive to do anything beyond absolutely necessary routine. If there be any reason in Capt. Freud's remarks, why should not the Veterinary Corps be charged with the care of our sick and wounded and the cost of a highly trained medical profession be eliminated? In other words, Why specialists? Why the Armour Institute of Technology? Why not have all its work done in high schools or in any other place than a special institute?

7. Next, Capt. Freud speaks on gas training and classes it as "a purely military matter." He goes on to state that it should be a part of the line officer's work. Yes, why not? Why not do away with all officers and let the Army be run entirely by non-commissioned officers? That would be vastly cheaper and simpler and would do away with a host of grades and organizations. Capt. Freud closes his remarks in regard to training by stating that: "Certainly scientists are not necessary

¹Prof. Freud's letter has been published in CHEM. & MET. ENG. vol. 21, No. 6, Sept. 15, 1919, p. 274.

for this duty." Let us see. I finally put at the head of gas training in France none other than Prof. G. N. Lewis (Lieutenant-Colonel, C. W. S.), head of physical chemistry, University of California, and one of the ablest and best known physical chemists in the world. I did this after two regular officers had been tried in the position and had failed. Col. Lewis succeeded because of his wide knowledge of chemistry, to which was added a highly trained mind with great vision and wonderful capacity to realize the possibilities of gas and the best methods of combating it.

8. Does not Capt. Freud know that the thoroughly trained gas officer needs a wider knowledge of all military tactics, of meteorology and of the topography of the battlefield than any other officer? Does he not realize that the weather, the woods, the knolls, the ravines, the wind and the sun must be taken into account not only with gases in general, but with each gas in particular? If this is not a job for specialists, then there is no need on earth for specialists.

9. Can your line officer be expected to acquire such knowledge or ability when rifle practice, hand-grenade throwing, machine-gun firing, and all the other multitudinous details that are required to make a highly efficient officer command all and more than all of his time?

10. Capt. Freud speaks also of the necessity of somebody writing a text on "Military Gases" of the same general character as Weaver's "Military Explosives." Weaver's "Military Explosives" was an excellent book in its day, but it is now out of date. Military gases and gas tactics of 1917 were out of date in 1918. Those of 1918 will be out of date in 1920. If we do not keep up with research, development, manufacture and training in gas, we, too, will be out of date, and *God pity us in the next war!*

11. Capt. Freud states that the offensive use of gas is largely an artillery problem and then suggests that gas troops might be put under the Engineers. This shows Capt. Freud's complete ignorance of the field of usefulness of gas troops. He apparently is not aware that the first regiment of gas troops was raised under the Corps of Engineers, and what happened? They were put on road work following the beginning of the Marne offensive and only relieved after their Colonel begged that they be given a chance to clean out German machine-gun nests that were killing our boys by the hundreds. This and other work they did so successfully that the General Staff, A. E. F., increased the gas companies to be used in the campaign in the spring of 1919 from 6 to 54; that is, the Staff increased them to nine times their original strength.

12. Capt. Freud believes that there should be a soldier-chemist on the staff of each Division. We had them, so far as possible, in the last war, but we also had three other officers, and each one of the four was kept busy to the absolute limit of his ability to cover the various requirements of the Commanding General concerning chemical warfare—and chemical warfare was only in its infancy.

13. Capt. Freud sums up and says it seems to him that the proper activities of the Chemical Warfare Service can be apportioned among the different Departments of the Army. Unquestionably, so might the activities of the Armour Institute be divided up among the country schools of Illinois. Unquestionably, if we wanted to revert to former weapons, we could abandon all organizations and modern forms of

warfare, and hence all technical services, and go back to the old short Roman sword—the deadliest weapon of warfare ever invented by man. Considering the highly complicated nature of gases and the need of research, experimentation, development and manufacture, it would be just as reasonable to state that the work of our colleges could be divided up among the country schools and the college done away with as to divide the proper work of the Chemical Warfare Service among other Departments of the Army.

14. In simple words again, Why specialists at all? As stated in the beginning, Capt. Freud furnishes the finest example I have ever known of the danger of "a little learning."

AMOS A. FRIES,

Lt. Colonel, C. W. S.

Glucium

To the Editor of Chemical & Metallurgical Engineering

SIR:—With reference to the article on Glucium, published in CHEMICAL & METALLURGICAL ENGINEERING, Sept. 15, 1919, page 353, the use of the name Glucium instead of Beryllium has been brought to my attention as needing some elucidation.

Since the publication of the first memoir by Vauquelin in 1798, to which is appended the editor's note using the word Glucine as the technical name of the Terre de Bérl, there has been published a voluminous series of papers on "Glucium or Beryllium" and "Beryllium or Glucium" and it seems that the Gordian knot is not yet cut. French technical literature uses exclusively the names Glucine (from *γλυκύς*, sweet, as one of the characteristic properties of its salts is a sweet taste) and Glucinium as analogous to alumine and aluminium. The Germans translated Terre de Bérl to Beryllerde, and they have their analogies: Beryllerde-Beryllium and Thonerde-Aluminium. In consulting the indices of the technical literature printed in English, one will find sometimes under Beryllium, "see Glucium," and quite as many times under Glucium, "see Beryllium."

Without going into the details of the printed discussions as to a proper name for this "chameleon element,"¹ it may be sufficient to state that when I used the word Glucium I was aware of the existence of practically all that is written on this subject.

Dr. Charles L. Parsons strongly advocates the name Beryllium, giving as the two reasons, priority and usage,² and sides with the "ninety and nine" who are using this term, although some time before 1905 the American Association on the Spelling and Pronunciation of Chemical Terms did recommend the term Glucium.

With the French it is not only a matter of priority and usage, but also that the sound of Glucine and Glucinium is far more harmonious and more expressive than Terre de Bérl and Bériillum, and this no doubt deserves to be taken into consideration when new words are to be created. With the Germans, on the other hand, it is strictly a matter of *magister dixit*. The translator of Vauquelin's memoir used Beryllerde in 1798 and Wöhler in 1828 wrote about Beryllium, *ergo* Beryllerde and Beryllium must be as immutable as Thonerde³ and Aluminium. With the English-speaking technical

¹Dr. J. Emerson Reynolds, *Chemical News*, July 9, 1883, p. 9.

²Dr. Charles L. Parsons, *Science*, Dec. 9, 1904, pp. 809-810.

³Dr. Charles L. Parsons, *Science*, Feb. 17, 1905, p. 273.

⁴Some changes have been made a few years ago in the German chemical nomenclature. Among these: The name Thonerde, which stands for Al_2O_3 , is now Tonerde.

man the use of Glucinum or Beryllium is, in the great majority of cases, determined by his *alma mater*.

Some writers favor Beryllia, because the use of Glucina (French, glucine), GLO, might lead to its being confused with glycine, $C_2H_5NO_2$. It is a fact that the sounds of the French *u* and *y* in glucine and glycine are hardly distinguishable to those who are not indigent and with a chemical education, and still the Frenchmen use exclusively Glucine. The Germans and the English-speaking people cannot claim that such an argument favors their choice of Beryllerde or Beryllia.

As to whether the English and American technical men shall use Beryllium in preference to Glucinum, I submit the following important authorities: *Journal of the Chemical Society*, London, and *Chemical News* both index Glucinum and not Beryllium (See *J. Chem. Soc.*, bound vol. 114, 1918, etc., and *Chemical News*, bound vol. 109-110, 1914, etc.); Bulletin 624, U. S. G. S., describes the mineral Beryl as a Glucinum-Aluminum silicate; the Van Nostrand Chemical Annual, 1918, uses Glucinum, and only in a few places is the word Beryllium mentioned and then only in parentheses after the word Glucinum; the Chemist's Pocket Manual, 1918, uses Glucinum; lastly, the Condensed Chemical Dictionary, edited by the editorial staff of the *Chemical Engineering Catalog*, just issued (September, 1919), indexes on page 104 "Beryllium; see Glucinum," on page 243 "Glucinum (Beryllium)," and on page 503 "Glucinum."

In conclusion I will quote what Professor James Lewis Howe stated about 15 years ago: "With French, English and Americans using 'Glucinum,' we can afford to let the Germans cling to 'Beryllium' a little while longer."⁶

Western Chemical and Metallurgical Field

Potash Salts

NO ACTION has as yet been taken by the Ways and Means Committee regarding the bill to license potash importations. Rather the opposite—in order to provide the necessary additional potash needed this fall by the agricultural industry in addition to that produced from American sources, a recent Executive order opens the door to potash regardless of the fact that it may have been produced in Germany.

Whether the German or Alsatian supplies are sufficient for our needs remains to be seen. Conditions in Germany as regards potash are in an uncertain and disorganized state. There are no large quantities of potash available for export to this country, labor conditions are uncertain, the mines are wholly run down, transportation difficulties are many, and the coal shortage has been acute for some time. Shipping facilities are also in an uncertain condition. For these reasons, the Bureau of Mines states, the quantity of potash which may be expected to come out of Germany this fall is hard to estimate. The general director of the Potash Syndicate believes that Germany may be able to supply all the potash salts needed of the lower grades, provided boats are secured.

In addition to these uncertainties, there is also the question of what the national policy of Germany with

regard to potash will be. There may be heavy taxes placed on the export of potash to raise revenue.

In Alsace it is reported that on the first of July there were from 15,000 to 20,000 tons, but that this was largely needed for domestic use. It has been estimated by H. S. Gale that there may be available during the next year, that is, up to the middle of 1920, 50,000 tons of pure potash from Alsace and an equal quantity from Germany, which together would not be nearly enough to satisfy our pre-war requirements. It is reported that the accumulated stocks of Nebraska potash have all been sold.

Alpha-Naphthol and Xylidine Mixture as Flotation Agent

The annual report of the Consolidated Coppermines Co. contains interesting information as to the results obtained in its concentrating operations during the past year and a half. Previous to Sept. 1, 1918, a coal-tar composition consisting of a mixture of coal-tar, coal-tar creosote and No. 80 Pensacola pine oil was used in the flotation cells. Since that date a mixture of alpha-naphthol and xylidine in an alkaline circuit has been used with very encouraging results. The concentrating ratio has been increased from 14.68 to 17.0 to 1, and the moisture content of the filter cake reduced from 17.15 per cent to 9.39 per cent. The increased cost of reagents from 7.46c. to 15.6c. per ton milled was more than offset by the decrease in freight and smelter charges of more than half and by a three-fold increase in the capacity of the filter presses. In summarizing the results, H. S. Munroe states that the "operations for the year demonstrated that with a 1.4 per cent copper millhead and with a properly designed and operated mill the following results may be obtained:

"First: A concentrate containing 18 per cent copper may be produced.

"Second: The iron, sulphur and insoluble content may be governed within such limits as to permit of smelting this material with less than 20 per cent of barren flux.

"Third: The moisture of this concentrate may be held at 10 per cent or less."

A tabulation shows a comparison of results with the coal-tar float reagent and the X-cake reagent.

Mining Engineers Honor Hoover

HERBERT C. HOOVER was the guest of honor at a dinner given by the American Institute of Mining & Metallurgical Engineers at the Waldorf-Astoria, New York City, Tuesday evening, Sept. 16. The event commemorated his return to private life after 5 years of arduous service in administering the food supplies of many nations and participating in the economic readjustment of Europe after the Armistice. Over 1200 members of the Institute responded to the opportunity to honor their eminent fellow engineer, and the occasion was one not often paralleled, if equaled.

In the course of the evening those present were presented with a photograph of Mr. Hoover which had been provided by the committee on arrangements.

President Horace V. Winchell opened the exercises with a brief tribute to the ability and genius of the guest of honor, who has shown us that "the biscuit is mightier than the bomb." President Winchell then read letters and telegrams from various organizations and individuals, all paying tribute to Mr. Hoover's work. These messages came from: Brussels University, Robert W. Hunt, H. A. Garfield, J. C. Branner, American Engineers in London, Messrs. Honnold and Shaler, Institute of Mining & Metallurgy, Commission for Relief in Belgium, L. D. Ricketts, Members of the A. I. M. E. in London, Van H. Manning, Belgian Society of Engineers and Manufacturers of Brussels, John Hays Hammond, Trustees of Stanford University, Charles T. Neal, D. W. Brunton, Charles M. Schwab, the Commonwealth of California, Joint Council of San Francisco Engineering Societies and Henry M. Howe.

President Winchell then introduced W. L. Saunders, past president of the A. I. M. E., who acted as toastmaster. Mr. Saunders repeatedly evoked applause and cheers by his reference to the work and character of Mr. Hoover, and when he made reference to the fact that men like Hoover "are, by education and experience, best fitted to steer the ship of State" he brought the entire audience to its feet with cheers of approval for the evident political import of the remark.

Mr. Hoover responded with a brief expression of gratitude for the honor shown him and then delivered a formal address on some of the impressions gained during his service in Europe since the armistice. This address we deem of sufficient importance in these trying times to reproduce in full.

Mr. Hoover's Address

I have been asked to speak to you on some of the impressions that I have gained during my service in Europe since the armistice. Two convictions are dominant in my mind. The first comes from contact with stupendous social ferment and revolution in which Europe is attempting to find solution for all its social ills by practical experiments in Socialism. My conviction is that this whole philosophy is bankrupting itself from a startling quarter in the extraordinary lowering of productivity of industrial commodities to a point that, until the recent realization of this bankruptcy, was below the necessity for continued existence of their millions of people. My second conviction is older but has been greatly hardened, and that is a greater appreciation of the enormous distance that we of America have grown away from Europe in the century and a half of our national existence, in our outlook on life, our relations toward our neighbors,

and our social and political ideals. The supreme importance of this Americanism neither permits us to allow the use of this community for experiment in social diseases, nor does it permit us to abandon the moral leadership we have undertaken of restoring order in the world.

ECONOMIC EXHAUSTION RAMPANT

During the last ten months I and my colleagues have occupied a unique position in intimate witness of the social currents that have surged back and forward across Europe. The enemy collapsed not only from military and naval defeat but from total economic exhaustion. In this race to economic chaos the European Allies were not far behind. By this exhaustion the whole of Europe stood facing a famine, the like of which has not been seen since the Thirty Years' War, when a third of the population died of starvation. In the midst of all this was the struggle of a score of new democracies to establish themselves, with friction along every frontier, and with the destruction of governmental institutions, without financial resources to buy supplies, with the miseries of their people offering fertile soil for every economic patent medicine and for all the forces of disorder, and Bolshevism and anarchy overhanging all, there could be no hope of restoring normal economic life until the completion of peace. In all this situation, with its desperation, greed, century-old animosities, its idealistic and proper aspirations, there was only one hope. That hope, expressed by every city and state, was that the American people, being the one disinterested and unripped economic and political force still existing in the world, should again intervene. It was in response to this call that the President, comprehending the real heart of the American people, intervened in Europe a second time and took those steps which resulted in a practical economic organization of Europe, pending the consummation of peace and the arrival of the forthcoming harvest.

PROBLEM OF THE SECOND INTERVENTION

This second intervention was not a relief problem in the ordinary acceptance. It was not a problem alone of finding foodstuffs for starving populations of the ravaged regions. It was the problem of finding a large margin of foodstuffs and other supplies for the whole of Europe—Allies, liberated peoples, neutrals, and enemies; and in a mass of at least 200 millions of these people formerly under enemy domination it was a problem of finding absolute economic rehabilitation. Further than this, it was a problem of warding off Bolshevism on one side and reaction on the other, in order that the new-born democracies could have an opportunity of growth. Its practical consummation was a problem of the organization of the economic strength of the United States and its co-ordination with the remaining economic strength of Europe, and, in large areas, the imposition of absolute dictatorship over economic forces.

Thus, the shipping of the world required sufficient co-ordination to transport thirty millions of tons of supplies from all quarters of the globe to Europe. It required the provision of credits to those countries whose total exhaustion abolished all hope of normal payment. It required the insistence upon payment from those who had gold or commodities. It required sufficient co-ordination of purchase in this vast quantity of

supplies that the markets of the world should be affected in the least possible degree. With the dissolution of the organization of the old channels of communication, river craft and railway rolling stock was hoarded by each state; telegraph and postal communications were broken down; every frontier was the scene of more or less military friction, until at one moment there were twenty-five little wars in progress. Many of these new governments were without experience or even without the existence of departments for the conduct of either the transportation or distribution of supplies.

Thus, it was necessary to secure the erection within their governments of actual departments, to furnish them advisors, to take over the actual operation of thousands of miles of disintegrated railway systems, to open rivers and canals for traffic, to stimulate the production of coal and other primary commodities, to control their distribution through large areas, to find a basis for exchange of surplus commodities from one state to another, to exercise the strongest political pressure to obtain the disgorgement of surpluses into areas of famine, to resort to barter on a national scale where currencies had broken down, to stimulate peoples discouraged and disheartened to efforts in their own salvation, and, finally, but not least, to intervene a charitable hand in the saving of their children and the stamping out of contagious diseases, and through all of this economic disorganization to inspire the maintenance of order on one hand and the defeat of reaction on the other. Beyond this again, the necessity of constant friendly intervention in frontier quarrels to prevent the starting of more wars.

CO-ORDINATION SOLVED THE PROBLEM

These things have not been solved by the service or direction of any one man. They have been accomplished through co-ordination of the men of good will in twenty governments of Europe and throughout by creation of a thread of American personnel, directed from a single center. On our side it has required the co-operation of Congress, the Grain Corporation, the Treasury, the Shipping Board, the Army, and the Navy. A thousand Americans were sent into those communities with but little authority beyond their own assurance and the confidence on all sides that they were disinterested, that their only desire was to solve a great and human emergency for no political and no commercial advantage. It was our desire to do this from the background, without ostentation; to act at all times through established institutions, to build up their strength for the time they must rely upon their own resources. I cannot pay enough tribute to all these thousand Americans, many of them engineers, men taken from the common life of the United States, thrust into the face of staggering political, economic problems, the solution of which must affect the well-being not of hundreds but of millions. The proof of their performance lay in the fact that Europe has come through the most terrible period of its history with no loss of life from economic causes, with a stronger democracy and a glow in its heart for the United States.

This service of the American people has been accomplished at no mean national sacrifice. From the armistice to this year's harvest there has been furnished over two and a quarter billion dollars' worth of supplies, the majority of which has been given freely upon the undertaking of the assisted governments of repayment at some future date. There has been no demand

of special security; no political or economic privileges have been sought. It may be years before we receive any return from these loans, but if that period should never come the American people, by this second intervention in Europe, have saved civilization, and have done so with no thought to the burden or cost to themselves. These matters have been brought to a successful close with the arrival of the harvest and the prospect of peace. What the future has a right to demand from us in further economic support is not yet clear, but it is at least certain that if the world cannot quickly secure the settlement of peace and safeguards for the future through the League the whole of our two great interventions will have gone for nothing, and the menace of reaction will again return against us upon the winds of chaos.

COMMON PEOPLE'S CONDITION IMPROVING

As the executive head of this Allied effort in economic control, I have thus had an intimate contact with the common people and their officials. I have witnessed their improving physical condition, the constant change of currents of social, political and economic forces, their revolutions, and I have had to deal ultimately with the results of all these phenomena. During this period since the armistice, we have witnessed social and political revolution among one-third of the civilized world, and we see the remainder in great social tribulation. No contemporary can properly judge or balance the relative volume of great currents of social agitation. They are matters of mind and not of matter. Yet practical statesmanship requires that within our abilities a constant accounting should be taken of the tangible results of these forces abroad, if the development of our liberal institutions and progress of orderly government is to be maintained and revolution avoided.

This cataclysm of social change in Europe is the result of the long culmination of social as well as political wrongs; it is no sudden afterthought of war. These forces were projected into actual realization by the collapse of the war, the breakdown in the political institutions that had preceded it, and the misery that has flowed from it. Our soil is not so fertile as that of Europe to many of these growths, because we have a larger social conscience. We have not the vivid class and economic distinctions of Europe, nor have we the depth of misery out of which these matters can crystallize. Nevertheless, in these days of intimate communication, social forces are rapid in their penetration and social diseases are quick in universal infection.

The general revolution of Europe of the last century, starting with the French Revolution, profoundly changed the whole social order of the world, and, while in that revolution the spiritual impulse was the demand for political liberty, there was also a great economic impulse. That economic impulse was primarily the division of the land, and one of the fruits of that revolution was the better distribution of wealth among the agricultural population. Since that time an enormous expansion of mechanical industrialism has been superimposed upon all agricultural states, with a large increase in urban populations. The economic impulse of the revolution to-day is the demand for a better division of the wealth from this industrialism, and this time the agitation arises mainly from the urban population.

These vast masses of humanity in Europe have long been groping for the method of nearer equality of

opportunity and better distribution of the results of industrial production. These gropings and these attempts have in recent years been dominated by Marxian Socialism, developed in different degrees of intensity. Broadly, these revolutions have taken two forms: the Bolshevik form, through which there has been overnight communization of all property, and second, the milder form of legislative nationalization of industry. I believe we are now in position to take some stock of and to form some judgment as to the adequacy of these solutions for what I believe every liberal-minded man believes is a necessity—the better division of industrial production.

EUROPE'S INDUSTRIAL PRODUCTION DEMORALIZED

We require only a superficial survey to see that the outstanding and startling economic phenomenon of Europe today is its demoralized industrial production. Of the 450 million people in Europe, a rough estimate would indicate that they are at least 100 million greater than could be supported on the basis of production, which has never before reached so low an ebb. Prior to the war, this population managed to produce from year to year but a trifling margin of commodities over the necessary consumption and to exchange for supplies from abroad. It is true that in pre-war times Europe managed to maintain armies and navies, together with a numerically small class of non-producers, and to gain slowly in physical improvements and investments abroad, but these luxuries and accumulations were only at the cost of a dangerously low standard of living to a very large number. The productivity of Europe in pre-war times had behind it the intensive stimulus of a high state of economic discipline, the density of populations at all times responded closely to the resulting volume of production. During the war, the intensive organization of economy and consumption, the patriotic stimulus to greater exertion and the addition of women to productive labor, partially balanced the diversion of man-power to war and munitions. Both the pre-war and the war impulses have now been lost, and the productivity of Europe has steadily decreased since the armistice.

It is true that some of this diminution in production has been contributed to by the other factors, but in the larger degree the cause of this steady decrease of productivity, with its shortage of necessary supplies and its rising cost of living, must be sought in the social ferment, with its continuous imposition of Socialistic ideas. In this ferment the advocates of Socialism or Communism have claimed to alone speak for the downtrodden, to alone bespeak human sympathy, and to alone present remedies, to be the single voice of Liberalism.

We may examine these phenomena a little more closely. In Russia we have a great country in which the population, with the exception of a small minority, were comparatively well fed, warmly clothed, and warmly housed. They were subject to the worst of political tyranny, were deliberately steeped in ignorance and superstition, yet their productivity was sufficient to enable them to provide these primary comforts and to export more foodstuffs than the United States. Socialism was brought in overnight at the hands of a small minority of intellectual dilettantes and criminals, and this tyranny of minority, more terrible even than the old, has now had nearly two years in which to effect the conversion of the wicked competitive

system into the Elysium of Communism. Today two-thirds of the railroads and three-fourths of the rolling stock that they control are out of operation. The whole population is without any normal comforts of life and plunged into the most grievous famine of centuries. Its people are dying at the rate of hundreds of thousands monthly from starvation and disease. Its capital city has diminished in population from nearly two million to less than 600,000. Prices have risen to fantastic levels. The streets of every city and village have run with the blood of executions, nor have these executions been confined to the so-called middle and upper classes, for latterly the opposition of the workmen and farmers to this regime has brought them also to the firing squad in appalling numbers.

COMMUNISM ACKNOWLEDGING FAILURE

If we examine the recent proclamations of this group of mixed idealists and murderers, we find a radical change in their economic and social ideas. They have abandoned the socialization of the land, for they find the farmer will not produce for payment in high-flown and altruistic phrases. They have re-established a differential wage in an attempt to stimulate the exertion and ambition of skilled labor. They have established a State Savings Bank, in order to stimulate production through making provision for family and old age. They are offering fabulous salaries for men capable of directing the large agencies of production. In fact, while in the midst of flowery verbal endeavor to maintain that they are still Socialists, they are endeavoring to restore individual ownership of property and of the results of labor. The very High Priest of Socialism is today vainly endeavoring to save his people from their total destruction by summoning back the forces of production. The apologists of this debacle are telling us that it is due to the Allied blockade, and to various other oppositions, but any one with a rudimentary knowledge of Russia knows that they did have within their borders ample supplies of food, coal, oil, wool, flax, cotton, and metals and the factories with which to work them in abundance, and that their sole deficiency is human effort.

We could take another example of Bolshevism in the efforts of Bela Kun and his colleagues in Budapest. The distinction between this situation and Russia is that they were dealing with a population of much higher intelligence, of much higher average education, and it required but three months for the working people of Budapest to realize the fearful abyss into which they had been plunged. It was solely due to the efforts of the trade unions in Budapest that the Bolsheviks were thrown out of Hungary.

These are the extreme points where Socialism has had its opportunity for immediate and wholesale application, according to all of the precepts of its advocates. Elsewhere in Europe Socialism has proceeded through established institutions, and we may shortly examine the results here also.

During the war large measures were taken on both sides of the front to secure the mobilization of production and distribution to its maximum use in the struggle. There was effective socialization of vast sections of industry. These measures are being continued and extended today in many places by governments anxious to maintain the stability of institutions, even at the sacrifice of economic safety, but under the threat of minorities of revolutionary action. Yet

here again the same prime weakness has proved itself. The only partial success of these measures in war was due to the great patriotic impulse of war. Those who conducted these large operations were men whose initiative and capacity had been selected by the competitive system. These war impulses have been lost, and these organizations with constantly decreasing efficiency even in war now face disaster from further reduced productivity. All these decreases have immediate results in a rising cost of living or the necessity of governments to subsidize commodities—such as bread. There is no better example of this than the coal industry of Europe, and even omitting Russia, this production has fallen from a rate of 600 million tons per annum at the armistice to a rate of 450 million tons recently.

The coal industry is in modern life the very lifeblood of the state, and it has proved itself the most susceptible among all the industries to these influences, and its production today is at such an ebb as to jeopardize the entire social fabric. I am convinced that the greatest proportion of European leaders of Socialism today to some extent realize this bankruptcy, and are today endeavoring to cover a retreat with loud complaints as to the failure from other causes. Nevertheless, the realization itself is a great step and is bringing the turn of the tide, and through it Europe is on the road to economic recovery—if she gets peace.

▼ PRIMARY CONCEPTION OF SOCIALISM WRONG

The whole of these various sorts of Socialism are based on one primary conception, and that is that the productivity of the human being can be maintained under the impulse of altruism and that the selection of the particular human for his most productive performance can be made by some superimposed bureaucracy. Their weakness is the disregard of the normal day-to-day primary impulse of the human animal, that is, self-interest for himself or for his family and home, with a certain addition of altruism varying with his racial instinct and his degree of intelligence. They fail to take into account, also, that there is but one sufficiently selective agent for human abilities in that infinite specialization of mind and body necessary to maintain the output of the intricate machinery of production, and that is the primary school of competition.

My emphatic conclusion is, therefore, that Socialism as a philosophy of possible human application is bankrupt.

Although Socialism has now proved itself with rivers of blood and suffering to be an economic and spiritual fallacy and to have wrecked itself on the rock of production, I believe it was necessary for the world to have had this demonstration. Great theoretic and emotional ideas have arisen before in the world's history and have, in their bankruptcy, deluged the world with fearful loss of human life. A purely philosophical view might be that these experiences are necessary to humanity, groping for something better. It is not necessary, however, that we of the United States, now that we have witnessed these results, plunge our own population into these miseries and into a laboratory for experiment in foreign social diseases.

Bankruptcy of the Socialistic idea, however, does not relieve us from the necessity of finding a solution to the primary question which underlies all this discontent. That primary question is the better division of the products of industry and the steady development of

higher productivity. This bankruptcy of the Socialist idea should, if reaction is to be prevented, return the guardianship of this problem from the radical world to the liberal world of moderate men, working upon the safe foundations of experience.

SOLUTION OF AMERICAN ISSUES IN AN AMERICAN WAY

The paramount business of every American today is this business of finding a solution to these issues, but this solution must be found by Americans, in a practical American way, based upon American ideas, on American philosophy of life. A definite American substitute is needed for these disintegrating theories of Europe. It must be founded on our national instincts and upon the normal development of our national institutions. It must be founded, too, upon the fundamental fact that every section of this nation, the farmer, the industrial worker, the professional man, the employer, are all absolutely interdependent upon each other in this task of maximum production and the better distribution of its results. It must be founded upon the maximum exertion of every individual within his physical ability and upon the reduction of waste both nationally and individually. We can well see a vivid confirmation in Europe of the fundamental economic principle that the standard of living and the cost of living is the direct quotient of the amount of commodities produced; that we must secure a maximum production of the industrial machine if we wish to keep our population alive or if we wish to see an increase in the standard of living of our people. From this only can arise the very foundations of the higher activities of life. The application of this proposition must, however, stand several tests. A maximum production can only be obtained under conditions that protect and stimulate the physical and intellectual well-being of the producer. We shall never remedy justifiable discontent until we eradicate the misery which the ruthlessness of individualism has imposed upon a minority.

If I were thinking aloud I would say at once that this maximum production cannot be obtained without giving a voice in the administration of production to all sections of the community concerned in the specific problem; that it cannot be obtained by the domination of any one element. I would say that the human race had increased its standards of productivity and therefore of living through the growth of extraordinarily intricate organization of production and distribution based upon stimulation of the individual by the reward it offers. I would also say that it cannot be obtained from the destruction or sudden disturbance of this delicate and intricate organization of production and distribution or extravagance in its products. I would say the road lies along the better division of the more exorbitant profits that arise from these processes and that have accumulated from them. By better division of profits, I do not refer particularly to profit-sharing schemes but to the broad issue of the whole social product. Some are comparatively overpaid, and many comparatively underpaid, for the service they render to the community. Our organization in many aspects is not all that we could desire, but it is the best we have been able to evolve over thousands of years, and the destruction of these processes or of the organization which conducts them has been demonstrated to be the sure road to destitution and fearful loss of life.

It is not that we today have suddenly awakened to this necessity for better distribution of profits. The social conscience of this country has been manifesting itself continuously concerning this matter for years. We have in the United States today a better division of wealth and a greater equality of opportunity than any other nation in the world, and we have thus better foundation upon which to build. We have reason for discontent in the fact that our industrial development has outrun our social progress, and we have reason to hasten those measures that lead to larger justice in distribution of these profits, larger representation of all elements of the community in the control of these agencies to further strengthen our measures for the restraint of economic domination by the few and for the liquidation into the hands of the many of the larger industrial accumulations in the hands of the few that our rapid development has made possible.

Again I wish to repeat, the observation of these forces in Europe has reinforced my Americanism during these last ten months of intimate contact with them; it has revealed to me the distance of our departure from the political, social, and economic ideals of Europe. There has grown in this United States a higher sense of justice, of neighborly service, of self-sacrifice, and, above all, a willingness to abide by the will of the majority in every section of this community. This Americanism is the guarantee of the ability of our people to solve this most momentous internal problem confronting our generation. But these very ideals, this very sense of justice and service for our own people, gives us still further opportunities.

Our sister civilization in Europe is today recovering from a great illness. The many new democracies that we have inspired are striving for our ideals. We alone have the economic and moral reserve with which to carry our neighbor back to strength. To do this is also true Americanism.

During the evening Mr. Hoover was presented with an illuminated testimonial, a copy of which follows:

To
HERBERT HOOVER

THE Members and Guests of the American Institute of Mining & Metallurgical Engineers, assembled to commemorate his return home, extend the *Welcome* due an eminent American Citizen, a successful Engineer, a Genius of Constructive Administration, a practical Economist, a Statesman of World Vision.

In him they honor an Idealist who was able to vitalize the Altruism of America and save from Hunger and Anarchy vast areas of Europe where millions of men, women and children in a score of languages lift their voices to call him blessed.

He is loved and honored for his gift of leadership and inspiration which called many thousands of volunteers to his aid in the great tasks he undertook and accomplished.

Realizing that no gift of gold or precious stones could convey the deep feeling of appreciation we wish to express, we simply subscribe our names as fellow engineers, co-workers and admiring friends.

The World's Merchant Marine Tonnage

Lloyds Register for 1919-20, issued in August, shows that the world's total merchant tonnage is now 50,919,000 gross tons, compared with 49,090,000 gross tons in 1914, just before the outbreak of the European war. The totals of the steam gross tonnage in round numbers of the principal countries for the two years are separately stated. The 1919 steam tonnage for Germany is for the time of the armistice, and as Germany ceded to the Allies all ships over 1600 gross tons and from one-fourth to one-half of the remaining smaller ships, the actual German tonnage will be about 700,000 gross tons, and 2,550,000 gross tons will be divided among the Allies proportioned to war losses. Sail tonnage (net) comprises a small and diminishing part of the world's shipping and is added in at the end of the three columns following:

Countries	June, 1914 Gross Tons	June, 1919 Gross Tons	Increase (+) or decrease (-) Gross Tons
United Kingdom	18,892,000	16,345,000	-2,547,000
British Dominions	1,632,000	1,863,000	+ 231,000
United States:			
Sailing	2,037,000	9,773,000	+ 7,746,000
Great Lakes	2,260,000	2,160,000	- 100,000
Austria-Hungary	1,052,000	713,000	- 339,000
Denmark	770,000	631,000	- 139,000
France	1,922,000	1,962,000	+ 40,000
Germany	5,135,000	3,247,000	-1,888,000
Greece	821,000	291,000	- 530,000
Holland	1,472,000	1,574,000	+ 102,000
Italy	1,430,000	1,238,000	- 192,000
Japan	1,708,000	2,325,000	+ 617,000
Norway	1,957,000	1,597,000	- 360,000
Spain	884,000	709,000	- 175,000
Sweden	1,015,000	917,000	- 98,000
Other countries	2,427,000	2,552,000	+ 125,000
Total steam tonnage	45,404,000	47,897,000	+ 2,493,000
Sail tonnage (net)	3,686,000	3,022,000	- 664,000
Grand total	49,090,000	50,919,000	+ 1,829,000

An Engineering Course for College Professors

A banquet in the officials' dining room marked the closing of the annual summer course for engineering teachers at the East Pittsburgh works of the Westinghouse Electric & Manufacturing Co. Eleven college professors, representing institutions all the way from Brooklyn, N. Y., to Tokyo, were in attendance.

The course just completed was of a month's duration and was composed of inspection trips throughout the plant, observation of work, and of lectures and talks by the various experts of the company. A feature introduced at the lectures was the motion picture to portray the work of modern electricity. Two of the reels of the most interest were "A Romance of the Rails" and "A Trip Through the 74th Street Power House." The "Romance of the Rails" showed the advance in present-day railroading by electrification of steam roads and the passing of steam as motive power. The trip through the power house exhibited the 70,000-kw. turbine of the Interborough Rapid Transit Co. of New York City. This turbine, which was built and installed by the Westinghouse company, is the most powerful engine in the world.

The professors who were in attendance at the summer course and the institutions they represent are: M. P. Cleghorn of Iowa State College, W. D. Emerson of the University of Maine, R. S. Howell of the Georgia Institute of Technology, L. J. Hodgins of Maryland State College, J. E. Lear of the University of North Carolina, B. K. Northrop of Cornell University, S. Noda of the Imperial University of Japan, C. W. Piper of Purdue University, J. W. Shuster of the University of Wisconsin, A. F. Puchstein of the Ohio State University and E. B. Wood of Pratt Institute.

International Union of Pure and Applied Chemistry

THE July meeting of the Interallied Chemical Confederation¹ in London was devoted to the adoption of the statutes of the International Union of Pure and Applied Chemistry.

Previous to adjournment the Conference officially appointed members of its own body as their representatives, to attend the Brussels meeting of the International Research Council on July 22, for the purpose of effecting the union of the new international chemical organization with the International Research Council as its chemical branch, and for the purpose of making such necessary alterations in the statutes which have been adopted as might become necessary in uniting with the International Research Council.

The meeting at Brussels was largely engaged in the discussion, modification and final adoption of the statutes of the new International Union of Pure and Applied Chemistry. These statutes are printed herewith as finally adopted to conform with the statutes of the International Research Council, by and of which the International Union of Pure and Applied Chemistry was constituted the chemical section, in conformity with the resolutions adopted at the London meeting.

STATUTES OF THE INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY²

Article I

1. Each of the following countries—Belgium, United States of America, France, United Kingdom of Great Britain and Ireland, and Italy, through the agency of its National Research Council (Chemistry Division), or its Federal Council of Chemistry, or failing such national federation, through the agency of a national chemistry association, joins with the others in the formation of an International Union of Pure and Applied Chemistry, having for its objects the following:

(a) To cement among the allied peoples the bonds of friendship and mutual esteem which have been developed and strengthened during the course of the war.

(b) To organize permanent co-operation between the chemical associations of the different countries.

(c) To co-ordinate their scientific and technical activities.

(d) To contribute to the advancement of chemistry in all its branches.

2. The Union thus constituted shall be perpetual. Its provisional headquarters shall be in Paris.

Article II

1. The conditions governing the admission of a country to the Union shall conform to those fixed by the statutes of the International Research Council.

2. A country may join the Union through its "national chemical federation," e.g., through its National Research Council (Chemistry Division), or through its Federal Council of Chemistry, or failing such organization, through a national association representing chemistry.³

¹See CHEM. & MET. ENG., vol. 21, No. 5, Sept. 1, 1919, p. 234.

²This is a free and unofficial translation of the French text. A committee was appointed to prepare an authorized English version.

³TRANSLATOR'S NOTE.—The purpose of this paragraph is to provide for the formation in each country of some national agency which shall federate all of the major chemical organizations of the country. Thus in the United States this federation is effected through the Chemistry Division of the National Research Council, while in England it is effected through their Federal Council of Chemistry. Ultimately it is expected that in each country the federating agency will become merged in the National Research Council of that country in the capacity of its Chemistry Division.

Article III

1. The functions of the Union as set forth in Article I shall be exercised through a Council, assisted by an Administrative Secretary and by a special staff or bureau, the establishment and duties of which shall be determined by international agreement among the constituent countries.

Article IV

1. The annual subscription for each country is fixed at a rate dependent upon the number of its inhabitants, in accordance with the following categories:

	Population in Millions of Inhabitants	Minimum Annual Subscription, Francs
Category A.....	Less than 5	500
Category B.....	From 5 to 10	1,000
Category C.....	From 10 to 15	1,500
Category D.....	From 15 to 20	2,000
Category E.....	From 20 to 30	2,500
Category F.....	More than 30	3,000

2. The inhabitants of any non-self-governing colonies or protectorates of a country may, at the discretion of that country and in accordance with its own census data, be counted with its own inhabitants.

3. No member of the Union may without its own consent be assessed by the Union to provide funds for other than general administrative expenses.

Article V

1. Any member of the Union may withdraw therefrom, provided said member shall have fulfilled all of its current obligations.

2. A member of the Union may be expelled or dropped from membership by a three-fourths vote of the members of the Council, either present or represented, for non-payment of the minimum annual subscription or for a serious offense, the member having previously been called upon to furnish explanations.

Article VI

1. The Union shall be administered by a Council composed of the delegates of the constituent countries, the members and distribution of such delegates to be determined by the categories of Article IV in accordance with the following table:

Delegates		Delegates	
Category A.....	1	Category D.....	4
Category B.....	2	Category E.....	5
Category C.....	3	Category F.....	9

2. These delegates shall be appointed for a term of three years by the "national chemical federation" of the respective countries. One-third of the membership of the Council shall retire annually but the retiring members shall be eligible for re-appointment.

Article VII

1. The executive functions of the Council shall be exercised through a committee of the officers, which shall be a president, four vice-presidents, and a general secretary. These officers shall be elected by the Council from among its own membership by a majority vote. They shall serve for terms of three years and, with the exception of the general secretary, shall not be eligible for immediate re-election to the same office. The president shall be chosen from among the vice-presidents.

Article VIII

1. The Council shall meet at least once a year on the day before the annual general meeting in the town where the latter is to be held, and in addition as often as it shall be convened by its president, or upon the requisition of one-fourth of its members.

2. The Council shall fix the date and place of meeting, draw up the budget, and decide as to expenses.

3. Resolutions shall be adopted by a majority.

4. On questions of an administrative or financial nature the voting shall be by countries, each country having a number of votes equal to the number of its delegates. In such voting it is, however, not necessary that all these delegates be present. The delegates of any country may appoint one or several proxies to represent them and to vote in their name.

5. Voting by correspondence is permitted.

6. All questions to be voted upon must appear on the agenda of the meeting.

7. The president shall have the casting vote in case of a tie.

Article IX

1. Minutes shall be kept of all meetings. Two copies of the minutes shall be prepared and signed by the chairman and the secretaries of the meeting.

2. The permanent secretarial staff shall have the custody of the archives, and shall be entrusted with the execution of the decisions taken by the Council and by the committee of officers and in particular with the circulation of the agenda.

Article X

1. The functions of the committee of officers shall be:

(a) To see that the rules are strictly observed.
(b) To prepare the agenda for meetings of the Council.

(c) To record and carry out the decisions of the Council.

(d) To perform during the entire period elapsing between two meetings of the Council the necessary acts of administration and to report the same in writing to the members of the Council.

(e) To submit to the Council a yearly budget draft.

(f) To represent the Union or to appoint its representatives.

Article XI

1. There shall be instituted, in addition to the Council, a consultative committee, consisting of as many sections as shall be necessary to insure the complete representation of pure and applied chemistry in conformity with the regulations of the Union.

Article XII

1. The General Assembly of the Union shall consist of the members of the Council and of the delegates of the "national chemical federation" of the constituent countries.

2. A regular meeting of the General Assembly shall be held at least once a year, preferably at the time and place of the meeting of the International Congress of Pure and Applied Chemistry.

3. The General Assembly shall also meet when called together by the Council or when such meeting is requested by at least one-half of the members of the Union.

4. The General Assembly shall receive reports on the administrative work of the Council, on its financial situation, and on the general condition of the Union.

5. It shall approve the accounts of the previous fiscal year as certified by an auditor, selected from outside the membership of the Council and appointed by the General Assembly of the preceding year.

6. It shall pass upon the budget for the next fiscal year and shall discuss those questions appearing upon its agenda.

7. The annual report and the financial statement shall be sent each year to all the members three months

in advance of the annual meeting of the General Assembly. The agenda of the General Assembly shall be drawn up by the Council and must include every question which shall have been transmitted to it by any of the members of the Union three months in advance of the meeting of the General Assembly.

8. The officers and executive committee of the General Assembly shall be identical with those of the Council.

9. Votes on administrative and financial questions shall be cast by countries, each country having the number of votes indicated in the categories of Article VI.

10. The delegates of any country may appoint one or several proxies to represent them and to vote in their name.

Article XIII

1. All expenditures shall be authorized by the president and disbursed through the administrative secretary.

2. The spokesman and representative of the Union before the public and in all legal matters and court proceedings shall be its president, who may, however, delegate his powers in this respect to the administrative secretary or to any member of the Council.

Article XIV

1. Resolutions of the Council relating to such purchases, exchanges and transfer of real property as may be needed for the accomplishment of the objects of the Union, grant of mortgages on the said properties, leases for more than 9 years, transfers of properties and loans, must be submitted to the General Assembly for approval.

Article XV

1. Amendments to these statutes may be considered and voted upon by the General Assembly only when submitted thereto by the Council of the Union or proposed by a "national chemical federation" of one of its constituent countries. All such proposed amendments shall appear upon the agenda of the meeting of the General Assembly, provided they have been received in writing by the committee of officers at least three months in advance of the meeting.

2. Voting upon amendments shall be by countries in accordance with the categories of Article VI.

3. Voting by correspondence is permitted.

4. The statutes may be amended only by a two-thirds majority of the votes cast.

Article XVI

1. In the event of a meeting of the General Assembly being convened to decide upon the dissolution of the Union, special notices to that effect shall be sent three months in advance; and at least three-quarters of the members of the Union or their proxies must be present. If this proportion is not reached, the General Assembly shall be adjourned for not less than six months, when the decision of the adjourned meeting shall be operative, irrespective of the number of members present.

In any case, dissolution can only be resolved upon by a majority of two-thirds of the votes cast.

Article XVII

1. In the event of dissolution the General Assembly shall appoint one or more trustees to liquidate the property of the Union; and any surplus assets shall be donated to an international institution.

Article XVIII

1. In the interpretation of these statutes the French text shall be authoritative.

Eighth Annual Safety Congress

THE National Safety Council will hold its Eighth Annual Safety Congress at the Hotel Statler, Cleveland, Oct. 1 to 4, 1919. During the week of the Congress, the people of Cleveland will endeavor to excel the record established by St. Louis in its "Safety Week" last year. They have undertaken a difficult task, for the achievement of St. Louis was remarkable. In that city during Safety Week there was only one death from accident (an intoxicated man killed in falling from a wagon), whereas during the previous week there were ten accidental deaths and during the corresponding week of the previous year there were twenty-four. But the enterprising spirit of Cleveland recognizes no limitations in a great humanitarian work of this kind. Every man, woman and child in the city will be on the alert to prevent accidental injuries during the special campaign. Every factory, every school, every home, all the educational and social forces in the entire community will be enlisted in one great life-saving effort. The goal is *no accident* during Congress week. A large clock on the Cleveland Trust Co. building near the Hotel Statler will register the record each day.

TIME-TABLE OF MEETINGS

Sessions	Wednesday Oct. 1	Thursday Oct. 2	Friday Oct. 3	Saturday Oct. 4
Registration.....	9: a.m.			
Annual Meeting of Members.....	10:00 a.m.			
Directors' Meeting.....	5:00 p.m.			
Executive Committee Meeting.....		5:00 p.m.		
Reception and Informal Dance.....	9:00 p.m.			
Informal Dinner and Smoker Banquet (Informal).....		7:00 p.m.	7:00 p.m.	
GENERAL SESSIONS:				
Employees' Representation.....	2:00 p.m.	2:00 p.m.	2:00 p.m.	
Health.....				2:00 p.m.
Safety Education.....				
ROUND-TABLES:				
General Round-Table.....		8:00 a.m.		
A. B. C. Session.....		9:30 a.m.		
Employees' Benefit Associations.....			9:30 a.m.	9:30 a.m.
Employees' Publications.....		12:30 p.m.	12:30 p.m.	
SECTIONAL MEETINGS:				
Bulletins.....		9:30 a.m.	9:30 a.m.	
Automotive.....		9:30 a.m.	9:30 a.m.	
Cement.....		9:30 a.m.	9:30 a.m.	
Chemical.....		9:30 a.m.	9:30 a.m.	
Construction.....		9:30 a.m.	9:30 a.m.	
Electric Railway.....		9:30 a.m.	9:30 a.m.	
Health Service.....			9:30 a.m.	9:30 a.m.
Local Council Officers.....			9:30 a.m.	9:30 a.m.
Marine and Navigation.....				9:30 a.m.
Metals.....		9:30 a.m.	9:30 a.m.	9:30 a.m.
Mining.....		9:30 a.m.	9:30 a.m.	9:30 a.m.
Packers.....		9:30 a.m.	9:30 a.m.	9:30 a.m.
Paper and Pulp.....		9:30 a.m.	9:30 a.m.	9:30 a.m.
Public Safety.....			9:30 a.m.	9:30 a.m.
Public Utilities.....			9:30 a.m.	9:30 a.m.
Rubber.....				9:30 a.m.
Steam Railroad.....		9:30 a.m.	9:30 a.m.	9:30 a.m.
Textile.....		9:30 a.m.	9:30 a.m.	9:30 a.m.
Women in Industry.....		9:30 a.m.	9:30 a.m.	9:30 a.m.
Wood-working.....			9:30 a.m.	9:30 a.m.

EXHIBIT—Opens Monday, Sept. 29, 8:00 p. m. Open daily 11:00 a. m. to 11:00 p. m. Grays' Armory. Closes Saturday 6:00 p. m.

The following papers will be presented at the sessions of the Chemical Section, of which E. H. Fiesinger, safety engineer, Solvay Process Co., is chairman:

THURSDAY MORNING

9:30—"Supervision of the Chemical Industry From the Point of View of Accidents and Occupational Diseases," Dr. Alice Hamilton, United States Bureau of Labor Statistics, Washington, D. C.

10:15—"Lead Poisoning and Its Prevention," C. P. Tolman, chairman manufacturing committee, National Lead Co., New York City.

11—"Dangers in the Manufacture of Dyes," Dr. L. C. Cone, National Aniline & Chemical Co., Buffalo, N. Y.

FRIDAY MORNING

9:30—"The Controlling Factors in Gas Mask Design," Dr. W. K. Lewis, Massachusetts Institute of Technology, Cambridge, Mass.

10:15—"Some Experience in Accident Prevention in the Dye Industry," A. H. Massey, E. I. du Pont de Nemours & Co., Wilmington, Del.

11—"The Failure of Materials Due to Chemical Action," E. G. Rippel, sales manager Buffalo Foundry & Machinery Co., Buffalo, N. Y.

The Metals Section will hold three sessions, at which the following papers will be read:

THURSDAY MORNING

9:30—"Accident Prevention in a Malleable Iron Foundry," H. L. Church, Rockford Malleable Iron Works, Rockford, Ill.

10:15—"The Personal Element in a Safety Program for the Foundry," M. F. Gartland, Marion Gray Iron Foundry Co., Marion, Ind.

11—"Safety in the Steel Foundry."

FRIDAY MORNING

9:30—"Consider the Crane," C. C. Rausch, assistant director Safety Institute of America, New York City. Discussion by O. J. Lewis, McKinney Steel Co., Cleveland, Ohio.

10:15—"New Ways to Put Safety Across in a Steel Plant," H. P. Wayne, United Alloy Steel Corporation, Canton, Ohio. Discussion by H. W. Darr, Cambria Steel Co., Johnstown, Pa.

11—"Practical Demonstration of Investigating Accidents," court of inquiry staged by H. J. Weeks with employees of American Steel & Wire Co.

SATURDAY MORNING

9:30—"How the Foremen Cut Lost Time Accidents," James F. Belford, acting secretary of labor, safety and welfare, American Smelting & Refining Co., New York City. Discussion by E. E. Judd, American Smelting & Refining Co., Omaha, Neb.

10:15—"Humanizing a Steel Plant," Philip Stremmel, superintendent hot mills, National Enameling & Stamping Co., Granite City, Ill. Discussion by Raymond G. Adair, safety engineer, American Rolling Mills Co., Middletown, Ohio.

11—"Practical Demonstration of Welding and Cutting," J. Schleicher, the Alexander Milburn Co., Baltimore, Md. (All present to have welding goggles furnished by various manufacturers.)

The Safety Exhibit to be shown at Grays' Armory will be unquestionably the most pretentious and elaborate ever shown in America. Practically all of the leading manufacturers of safety devices will be represented. This feature of the Congress will be presented under the joint auspices of the National Safety Council and the Safety Institute of America.

The exhibit will be opened at 8 o'clock, Monday evening, Sept. 29, and will be open thereafter between 11 a. m. and 11 p. m. daily. It will close Saturday, Oct. 4, at 6 p. m.

The exhibit will be open free to the public. Workmen and their families are especially invited to view the exhibits in the evening of any day during Congress week.

Chicago Exposition and Conventions

EVERY available space was filled in the great Coliseum, in which the Chemical Exposition was held in Chicago. The first impression on looking down from the gallery was that the main floor exhibits were divided into three sections by aisles.

The combined exhibit along the center aisle made by the General Chemical Co., the Barrett Co., the Semet-Solvay Co. and the National Aniline & Chemical Co. struck a new note in technical exhibitions by calling in the art of the architect in structural design and interior decoration and that of the artist in paint. Every detail was worked out with artistic feeling and understanding and the insignia of the Chemical Warfare Service were used with charming effect. The services of Arthur Covey, a sound painter, were availed of, and along the walls we found very decorative panels of the interior of a dye house and of a synthetic color works. A picture of Herreshoff furnaces in operation with heaps of Spanish pyrites to balance the composition in general challenged the eye to closer inspection, and it did all this unconsciously. Art pays.

THE OFFICIAL OPENING

It is curious how we are tied to conventions. In olden days when royalty visited a city the Mayor appeared in his robes of office and welcomed their Highnesses, pledging the constant devotion of the people, then serenity would respond in appreciation. When we have a convention or exposition nowadays we go through a similar performance. It is doubtful if the good people of Chicago were anxious to show their Mayor, and consequently on the opening of the Exposition the Governor of Illinois was to have made the address of welcome and our colleague, Dr. C. H. Herty, editor of the *Journal of Industrial and Engineering Chemistry*, was to have responded, but the one was in Washington and the other in Europe, so Chairman Redman of the Chicago Section bade all welcome and Manager Roth responded with felicity.

EXHIBITS OF SMALL-SCALE APPARATUS A FEATURE

The miniature and small-scale apparatus shown are features of the exposition. The Raymond Impact Pulverizer Co. had mills of several sizes in operation, the Dorr Co. showed its thickener and the General Bakelite Co. had a molding machine for making pressed beakers of Bakelite, the Redmanol Chemical Products Co. did similar work with Redmanol, making cigar and cigarette holders. The Industrial Filtration Corp. showed a rotary vacuum filter with which they separated diatomaceous earth. Other small units in operation included a Jewell still, a Proctor cotton drier and exhibit of the Philadelphia Drying Machine Co. Maurice A. Knight of Akron showed in operation a miniature acid pumping system that occupied hardly more than one cubic foot of space and the General Ceramics Co. exhibited a complete nitric acid plant in miniature but not operating.

INDUSTRIAL CHARTS

Making charts has become not only an art but a fashion. The coal tar chart of the Barrett Co. was considerably amplified over that of last year. The U. S. Industrial Alcohol Co. showed another of alcohol and the American Cyanamid Co. exhibited its raw materials and all products in sequence. The Hooker

Electrochemical Co. began with salt and water which it treats with electricity derived from Niagara Falls power and showed all its products. The Technical Association of the Pulp and Paper Industry gave a similar graphic representation of the making of paper. The New Jersey Zinc Co. exhibited Franklin ore and the various steps in making each product, ending with white rubber goods and objects in brass and zinc.

Not exactly in the form of a chart but nevertheless well displayed were the products of Shawinigan Falls, Quebec: Calcium carbide, acetylene, acetaldehyde, and acetic acid. In the same booth the Shawinigan Electro Metals Co. had an exhibit of magnesium and its uses, particularly as a deoxidizing agent as an alloy with aluminum to improve its strength, density, machining qualities, finish and polish.

MINING ENGINEERS

The first day of the meeting of the Institute was marked by a large registration and several technical sessions. The boat trip scheduled for Gary, Indiana, was definitely postponed on account of the steel strike and arrangements were made to hold the meetings in Chicago. The smoker on Monday evening was one of the best affairs of its kind ever held. George H. Rice, chief mining engineer of the Bureau of Mines, and Dr. F. G. Cottrell, assistant director, both of whom have recently returned from France, gave illustrated talks of their trip.

CHICAGO A BUSY HOST

The prospects for successful meetings of five of the leading American scientific and technical societies are excellent in spite of the unsettled industrial conditions. Chicago never before entertained so many scientific and engineering bodies in one week, and while it afforded an unusual opportunity for meeting men from all parts of the country the general consensus was that there was an undesirable congestion of such functions that should be avoided in the future if possible.

Borax in Searles Lake Potash

Investigation by the Department of Agriculture, it is stated officially, has developed that the potash put on the market by one of the companies operating on Searles Lake contained an injurious amount of borax. The investigation has not proceeded far enough to determine the character of the output of others operating in the same area. The salts which were examined showed an average of 10 per cent borax. Some samples went as high as 23 per cent borax, the Department states. The Bureau of Soils is in receipt of numerous complaints of crop injury resulting from the use of Searles Lake potash. The Bureau has satisfied itself that injury to crops will result when a sufficient amount of borax is applied with the potash.

Research Problems Before the Bureau of Standards

A total of \$440,000 for research work and materials is carried in the first deficiency appropriation bill, which just has been taken up by the House of Representatives. Industrial research calls for \$250,000 of the appropriation; testing government materials, \$100,000; industrial safety standards, \$25,000; standardization of instruments, \$50,000, and the purchase of platinum for laboratory use, \$15,000. The money is to be expended by the Bureau of Standards.

International Exposition of Mining Industries

The permanent exhibit of mining and metallurgical machinery planned by the Merchants and Manufacturers Exchange of New York¹ will open on Dec. 1, at Grand Central Palace.

One entire floor will be devoted to machinery, appliances, supplies and products pertaining to metal mining, non-metal mining, coal mining and the production of petroleum. Other floors will be devoted to other permanent expositions and exchanges of interest to engineers, such as material handling machinery, general machinery, factory appliances, municipal equipment and farm tractors and implements. Mr. Howard R. Ward, manager of the Exposition, who has recently returned from a trip through the West, reports widespread interest on the part of manufacturers and engineers interviewed. Some are especially attracted by the possibility of opening up business in foreign countries, some are considering it from a purely advertising standpoint, while others are planning to use the Exposition as their Eastern office or as an adjunct to their New York office.

The value of this centralized Exposition is readily appreciated. To the buyer it will be a center where he can accomplish the bulk of his purchasing in a short space of time, without traveling all over the country. To the manufacturer it will be a point of contact with the buyer. To the engineer it will be a center where he not only can study "standard practice" but will be able to see new devices and methods. New York is the logical point to which operators and engineers come to interest capital. Grand Central Palace will become the most convenient central point to which engineers, mine operators and purchasers will bring those whom they wish to interest financially.

New Headquarters for A. S. T. M.

The executive committee of the American Society for Testing Materials announces that the establishment of headquarters in the building of the Engineers' Club of Philadelphia, 1315-17 Spruce Street, forecast in its annual report to the Society, is now assured. It had become increasingly evident during the past year that the growing activities of the Society required an expansion which is not possible at the University of Pennsylvania, where the headquarters have been maintained under most pleasant and advantageous conditions since the incorporation of the Society in 1902.

The headquarters will be on the third floor of the building, where extensive alterations are now being made which will enable the Society to maintain very suitable headquarters.

The new headquarters are centrally located and convenient to the principal hotels and railway stations. The Engineers' Club is affiliated with the Philadelphia sections of many of the national engineering and technical societies, and is the center of engineering activities in Philadelphia. An auditorium on the second floor of the building, with a seating capacity of 125, and a committee room in the Society's headquarters will offer very satisfactory facilities for meetings of the committees of the Society. Out of town members may use the Society's headquarters as their mailing address while in Philadelphia, and facilities will be provided in the Society's rooms for correspondence.

¹See CHEM. & MET. ENG., vol. 21, p. 121, Aug. 1, 1919.

Bill Providing for Research on Oil Shales

Convincing reasons why the Bureau of Mines should undertake experiments looking to the commercial development of petroleum from oil shale have been presented to the Senate Committee on Mines and Mining. The committee recently took up the consideration of a bill by Senator Henderson of Nevada providing \$140,000 for such an investigation. The committee referred the bill to the Secretary of the Interior for his report. Mr. Lane submitted a lengthy review on the oil shale situation which he closed as follows:

"Experimental work must necessarily precede such a large undertaking as the development of the oil shale industry, and I recommend that such work start now so that at the time when the supply of petroleum from our wells does not meet the essential demands, then the oil from shale will be ready to alleviate partially this shortage. Favorable action by Congress upon such a measure as S. 2671 will help to bring about the desired results."

Civil Service Examinations

The following examinations are announced:

Metallurgist.—Vacancies exist in the Ordnance Department at Large for duty at manufacturing plants within the United States, at \$3400 to \$3600 a year. Closes Oct. 7, 1919.

Research Operator-Metallurgical.—The register of eligibles will be divided into two grades, Grade I, \$1500 to \$2000 a year, and Grade II, \$2000 to \$2500 a year. After six months' satisfactory service in Grade II, appointees will be eligible for promotion to Grade III, in which the salaries range from \$2500 to \$3000 a year. The duties of these positions consist of work in connection with research projects, either ferrous or non-ferrous, on ordnance materials. Although originally announced for Aug. 12, it is understood that it will be re-opened for another sixty days.

Physicist, Qualified in Optics.—The duties will consist of the supervision of the work of the optical division of the Bureau of Standards. Salary, \$3600 to \$4000. Oct. 14, 1919.

Minerals Relief Commission Resumes Work on Claims

The Shafroth Commission has returned from a visit to twelve cities, during which testimony was taken in 500 cases. The Commission came back with a clearer understanding of the situation and is prepared to dispose of claims rapidly from this time on. It is admitted by the Commission that the limitations of the act work injustices in numerous cases, and it is probable that the Commission will be requested, in the light of its experience, to suggest amendments to the act which will make it more equitable. Nevertheless, the Commission will dispose as rapidly as possible of the claims which clearly fall under the act as it now stands, allowing the other claims to await possible legislation looking to changes and liberalization of the law.

The National Pyrites & Copper Co. of Georgia has been awarded \$37,000 in full payment of its claim. The company asked \$189,723.43. This is the second award to be made, the first being that of the Chestatee Pyrites & Chemical Co., which was given \$219,607.90. The company claimed \$914,172.73. A third decision denied the claim of J. N. Lotspeich of Morristown, Tenn., who asked reimbursement for expenditures made in efforts to interest capital in certain manganese properties.

Meeting of the Rubber Division, American Chemical Society*

BY ANDREW H. KING

THE recent meeting of the Rubber Division of the American Chemical Society in Philadelphia was a decided success. More than 150 rubber chemists from different sections of the United States and Canada were present. An excellent program was given. The following is an effort to sum up in a few words the trend of the respective papers:

Report of Fruit Jar Ring Committee, L. J. PLUMB, chairman.—At the previous meeting of the old Rubber Section the seriousness of the fruit jar ring situation was ably pointed out. As a result this committee was appointed to take steps to secure satisfactory jar rings for the American housewife. Through their efforts and those of the Department of Agriculture the jar manufacturers have ceased putting poor rings in jars, and have secured the co-operation of ring manufacturers in producing only high-grade articles. Inasmuch as the Department of Agriculture has a large number of demonstrators at work, all of whom have been instructed to help educate the public to accept only good rings, the committee did not feel that further work on its part was necessary, and asked to be discharged, which was done.

Report of Committee on Physical Testing, H. E. SIMMONS, chairman.—The committee has prepared a tentative scheme for physical testing. A most pleasing feature of the report was the fact that the metric system was used throughout. Its decided advantage over the English system of units is well known. The time saved and the increased accuracy due to its simplicity make it by far the most efficient. We understand that it has been in use for two years at the Goodyear Tire & Rubber Co. in Akron, Ohio. Most of the tests advanced have been in use for some time. The committee tried only to correlate the best procedure in each case. A new method for permanent set was advanced and the arguments in favor of it were presented by E. L. DAVIES of the committee. The test recommended consists of three stretches to 60 per cent of the breaking elongation, held each time for 10 min. with a 10-min. interval between stretches and measuring 10 min. after release. Mr. Davies pointed out that 60 per cent of the breaking elongation is the most satisfactory, since over this figure, tearing becomes a serious factor. He also showed that the set developed on one stretch did not consist of any constant fraction of the total set obtainable and that three stretches bring out practically all the set possible. Set, he explained, is probably due to plastic flow in the rubber.

A New Method for the Determination of Sulphur in Rubber Mixtures, G. D. KRATZ, A. H. FLOWER and COLE COOLIDGE.—The new method recommended did not differ greatly from the old arsenious acid method except that zinc oxide was added instead of arsenious acid to raise the boiling point of the solution. The method was stated to be very rapid and also of a high degree of accuracy.

The Extraction of Rubber Goods, S. W. EPSTEIN and B. L. GONYO.—The authors used constant boiling point mixtures of acetone and carbon bisulphide and acetone and chloroform. They recommended the use

of the mixed solvent as a time saver to take the place of separate extractions by acetone and chloroform. Inasmuch as these extractions give valuable qualitative information, as for example, a fluorescent chloroform extract indicates MR or related hydrocarbons, it is not likely that the old method will be dropped for some time.

Theory of Balloon Fabric Protection, JOHN B. TUTTLE.—The author discussed the requirements balloon fabric must meet, the most important of which are low permeability to hydrogen, good aging and low visibility. He mentioned iron oxide as a good pigment for protection.

Balloon Seam Construction, J. W. EVANS.—Mr. Evans pointed out that the temperature inside the bag is 20 to 25 deg. F. higher than on the outside. The application of powdered aluminum as a reflector lowers the temperature on the inside by about 10 deg. F. He found that the high temperature was the cause of slippage at the seams. The most satisfactory cement was found to be a pure gum vulcanized by a dilute solution of sulphur chloride in carbon tetrachloride and benzol.

Expansion of Rubber Compounds, C. W. SANDERSON.—The author reported the cubic coefficient of expansion of brown crêpe as 4.68×10^{-4} per deg. F. Fine Para has about half this value. It was pointed out that milling has a marked effect on the expansion coefficient. The expansion of compounded stocks is almost entirely due to the rubber present. When rubber is heated at a constant temperature the expansion curve (expansion vs. time) shows a rapid rise to a flat, beyond which there is no further increase.

He also pointed out that the specific gravity of a stock increases when it is vulcanized under hydraulic pressure. The difference in gravity between raw and cured stock is probably due to contained air, which is either forced out or greatly compressed by the pressure employed. The contraction noticed for solid tires he placed at about 3 per cent.

Volume Increase of Compounded Rubber Under Strain, H. F. SCHIPPEL.—This paper was perhaps the most interesting of all those presented. The author pointed out an entirely new fact, that compounded rubber increases in volume when placed under strain. This increase was found to be quite high. Values as high as 120 per cent were obtained with whitening. Gas black and zinc oxide when compounded volume for volume against barytes showed much lower increase, due probably to adhesion of the filler to the rubber. Pure gum shows this phenomenon only very slightly. A series of experiments with barytes elutriated to several different sizes showed that the increase in volume was a direct function of the size of the particle. Mr. Schippel closed his paper with a very pretty experiment. A ring of about 2-in. diameter (internal) was stretched over a lump of paraffine. The specific gravity of the aggregate was very close to 1, and the block barely floated. When the ring was secured on the small end of the lump of paraffine without stretching, the paraffine and ring settled slowly to the bottom, thus proving beyond a doubt that the stock in question had a lower specific gravity when stretched.

The Determination of Cellulose in Rubber Goods, S. W. EPSTEIN and R. L. MOORE.—The method which was given in detail consists essentially of dissolving the rubber in cresol, filtering through a Gooch, washing well with benzene and then several times with hot 10 per cent hydrochloric acid until no further soluble mat-

* Annual meeting, Philadelphia, Sept. 4 and 5, 1919.

ter is removed. The crucible and contents are dried and weighed. The next step is acetylation with acetic anhydride, after which the cellulose acetate is removed by washing with acetone. Cellulose is determined by difference.

The Variability of Crude Rubber, JOHN B. TUTTLE.—This paper consisted chiefly of a résumé of previous work by Eaton and Grantham, de Vries and others. This is a subject on which not a great deal of work has been done in this country.

The Action of Accelerators During Vulcanization, J. H. SCOTT.—Detailed experiments by Spence and the author were described. These consisted of the introduction as dry powder of various alkaline substances, such as NaOH, Na_2CO_3 , $\text{Ba}(\text{OH})_2$, soda lime and MgO ; dipping in alkaline solutions; and the washing of rubber with caustic.

Considerable reduction in the period of vulcanization was shown by all alkalis tried. Zinc oxide was found to be an aid, while barytes was without effect. In addition the physical properties of the stocks were improved. Washing with alkali gave slightly improved physical properties but no decrease in time of vulcanization. Immersion in 5 per cent NaOH solution for 24 hr. produced a slightly shorter cure with a little higher tensile strength.

The author pointed out that alkalis are not satisfactory accelerators, due probably to the bad aging properties of the compounds. The fact that they are accelerators is of considerable theoretical interest. They probably function by the hydrolysis of the nitrogenous matter of crude rubber to amino acids, which are powerful accelerators, comparing favorably with piperidine.

Mr. Scott defined the ideal accelerator as one capable of bringing about vulcanization in the shortest possible time consistent with factory practice and which produces maximum polymerization. It should also be non-poisonous and easily handled. For some time it has been recognized by rubber chemists that accelerators have another effect than merely decreasing time of cure. The increase in tensile strength, snap, feel and nerve the author attributes largely to polymerization.

The Action of Certain Organic Accelerators in the Vulcanization of Rubber, G. D. KRATZ, A. H. FLOWER and COLE COOLIDGE.—This paper consisted of a review of experiments with aniline, urea, thiourea, mono-, di- and tri-phenyl thiourea and mono-, di- and tri-phenyl guanidine, anhydro formaldehyde aniline and para-phenylene diamine. The authors attribute the curing power of these accelerators to their decomposition at the temperature of vulcanization in the presence of sulphur-giving aniline, which they claim has a grouping which readily functions as a sulphur carrier. They recommend comparing accelerators in molecular quantities.

Reactions of Accelerators During Vulcanization, C. W. BEDFORD and WINFIELD SCOTT.—This paper is a reply to and a criticism of a recent paper by Dubosc in the *India Rubber World*. The authors stated that hexamethylene tetramine decomposes when heated with sulphur at the curing temperature and gives off CS_2 , NH_3 and H_2S , but no acetylene, as claimed by Dubosc. They also stated that methylene aniline decomposes when heated under similar conditions, giving CS_2 , aniline and thiocarbaniide.

The Effect of Organic Accelerators on the Vulcanization Coefficient, D. F. CRANOR.—The author

gave in detail the results of experiments with hexamethylene-tetramine and the addition product similar to thiocarbaniide produced by the action of CS_2 on dimethylamine. He showed that the coefficient of vulcanization bears no direct relation to the physical properties. He obtained a technical cure with the dimethylamine addition product when the coefficient of vulcanization was approximately 1.00. This falls in line with Scott's statement regarding the polymerizing influence of accelerators. Dimethylamine-dimethyl-dithiocarbamate is an extremely powerful accelerator. One-half per cent brings about a cure in 5 min. at 40 lb. steam.

Some Methods of Testing the Hardness of Vulcanized Rubber, H. P. GURNEY.—This paper consisted of a review of the different methods of determining hardness of rubber goods and contained data on the Shore hardometer and the Pussey-Jones plastometer.

The Manufacture and Use of Crimson Antimony, J. M. BIERER.—The author gave a detailed description of the preparation of crimson antimony, i.e., antimony oxysulphide. The important points on the preparation are purely of antimony trichloride solution, and the concentration of the acid used for precipitation.

Research on Zinc Products for the Rubber Industry, P. R. CROLL and I. R. RUBY.—It was pointed out that the New Jersey Zinc Co. is very desirous of improving the quality of its zinc oxide for the rubber industry and has installed a rubber division in its new research laboratory for this purpose. Lantern slides showing the ultimate particles of zinc oxide were exhibited. Zinc oxide is crystalline and the particles vary in size from 0.1 to 1 micron, the average being 0.5 micron. Their microscopic work is excellent and is fundamental to an understanding of compounding phenomena.

Carbon Black—Its Properties and Uses, ST. J. PERROTT.—This paper was delivered in the Division of Industrial Chemists and Chemical Engineers and proved so interesting that Chairman Tuttle invited Mr. Perrott to give it also before the rubber division. The manner of producing gas black by incomplete combustion of natural gas, allowing the smoky flame to strike a cold metal surface (air cooled) was illustrated by lantern slides. From the black cloud issuing above the plant shown, one would gather that technique of this industry is not very highly developed. Mr. Perrott showed several slides of micro-photographs of gas black and stated that the particles varied in size from 30 to 100 milli-microns.

The paper of H. E. SIMMONS on the value of a library to the rubber laboratory was not given, but will be published soon. Owing to the absence of GEORGE OENSLAGER his paper on the testing of pigments was held over until the next meeting of the Rubber Division. The paper of C. OLIN NORTH on the effect of compounding ingredients on the physical properties of rubber was unfortunately not in final shape for presentation, but will doubtless be given at the next meeting of the division.

ELECTION OF OFFICERS

The officers elected for the coming year are Dr. WARREN K. LEWIS, chairman; and ARNOLD H. SMITH, secretary. Dr. Lewis is a well known member of the chemical engineering staff of Massachusetts Institute

of Technology and has been acting as consulting engineer to the Goodyear Tire & Rubber Co. for several years. The Rubber Division is fortunate in securing the services of Dr. Lewis, who is widely known because of his ability to "start something." Mr. Smith is the efficient secretary who served the Rubber Division so well this year.

A rising vote of thanks was tendered the retiring chairman, Mr. Tuttle, who has perhaps had more to do with the organization of the Rubber Division than any other rubber chemist, and to whose untiring efforts, with those of Mr. Smith, the success of the recent meeting was largely due.

The success of the Rubber Division is now assured. As was pointed out by Dr. CHARLES L. PARSONS in a brief talk, it was only necessary that the rubber chemists should meet and get acquainted, when they would cease being suspicious of one another and would jump in and make the thing a success. It augurs well for the rubber industry.

Iron and Steel Output

The London *Economist* of May 31, 1919, gives the following figures for the iron and steel output of the chief producing countries before and during the war:

Year	PIG IRON		Germany (Metric Tons)	France (Met. Tons)
	United Kingdom (Long Tons)	United States (Long Tons)		
1900	8,960,000	13,789,000	8,521,000	2,714,000
1905	9,608,000	22,992,000	10,988,000	3,077,000
1910	10,012,000	27,304,000	14,793,000	4,032,000
1911	9,526,000	23,650,000	15,534,000	4,939,000
1912	8,751,000	29,727,000	17,753,000	4,939,000
1913	10,260,000	30,966,000	19,292,000	5,207,000
1914	9,924,000	23,352,000	14,392,000	†
1915	8,794,000	29,916,000	11,790,000	†
1916	9,048,000	39,435,000	13,285,000	1,447,000
1917	9,420,000	38,621,000	13,142,000	1,684,000
1918	9,066,000	39,052,000	11,590,000	1,297,000

Year	STEEL		Germany (Metric Tons)	France (Met. Tons)
	United Kingdom (Long Tons)	United States (Long Tons)		
1900	4,901,000	10,188,000	6,646,000	1,565,000
1905	5,812,000	20,024,000	10,067,000	2,240,000
1910	6,374,000	26,095,000	13,699,000	3,390,000
1911	6,462,000	23,676,000	15,019,000	3,681,000
1912	6,796,000	31,251,000	17,302,000	4,428,000
1913	7,664,000	31,301,000	18,950,000	4,687,000
1914	7,835,000	23,513,000	14,973,000	†
1915	18,550,000	32,151,000	13,258,000	†
1916	19,196,000	42,774,000	16,183,000	1,952,000
1917	20,804,000	45,061,000	16,587,000	2,232,000
1918	19,591,000	45,073,000	14,674,000	1,912,000

* Including Luxembourg up to October, 1918. The returns for November and December, 1918, do not include the production of Luxembourg, Saar district and the disannexed Lorraine Provinces.

† No returns.

‡ Including steel castings.

United States Platinum Corporation Proposed

A concern to be known as the United States Platinum Corporation, to be chartered by Congress and to be supervised by a Government commission of five members, is proposed in a bill introduced by Representative O'Connell of New York. The operations of the company are to be confined to the public domain in Alaska. A royalty of one-eighth of the net products obtained from platinum sands is to be paid to the Government. L. R. Beckley and unnamed associates are the incorporators of the proposed corporation.

German Production of Fertilizers

According to the *Deutsche Allgemeine Zeitung*, the production of certain fertilizers in Germany during 1913-14, 1917-18, and 1918-19, was:

Articles	1913-14 Tons	1917-18 Tons	1918-19 Tons
Nitrogen	210,000	92,334	80,000
Phosphoric acid	510,000	325,000	220,000
Potash	557,350	779,400	520,000

Engineering Council Addresses the President Regarding United States Maps

Engineering Council, through its chairman, J. Parke Channing, has brought to the attention of the President the lack of co-ordination among the official map-making agencies of the Government. Setting forth the fact that every industry, art and science which demands a knowledge of the lay of the land is dependent upon suitable maps, and emphasizing the value of co-ordinating governmental efforts on the making of a base map of suitable accuracy and scale, Mr. Channing called to the attention of the President the fact that the official map work of the United States is now being prosecuted by 12 separate and distinct Federal agencies. Most of these agencies are making maps for special purposes, which are of little value for any other purpose. The amount of money now being expended would, if covered into a well-co-ordinated mapping plan, produce better and more useful results than that which now can be shown by the aggregate production of all Government map-making agencies. A portion of the argument presented follows:

"Engineering Council believes that the chaotic condition above described is wrong. It makes this presentation to the Executive because he is the one authority having jurisdiction over all of the Federal agencies above mentioned. It is the opinion of Council that the most purposeful way to bring order into map making and to expedite the completion of our topographic map is to appoint a Board of Surveys and Maps consisting of a representative from each of the present Federal map-making agencies, together with representatives from well-qualified map-using agencies, which would be vested with authority to work out a plan of standardization and co-ordination of the work of the Government, and to report the same to the President for such action as he may find wise.

"In order to give further definition to the present petition and to facilitate your consideration thereof, Engineering Council suggests the following unofficial bodies as the proper ones to participate in the work of the Board: The American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Association of State Geologists, the National Research Council, the American Association of State Highway Officials and the Engineering Council."

Government Disposes of Surplus Phenol

Thirty million pounds of phenol, the entire surplus stock of the War Department, has been sold to the Monsanto Chemical Works of St. Louis and New York. The Monsanto company has agreed to resell this phenol at prices to be fixed by the War Department, but is to receive a 2 per cent commission to cover the expenses of selling. The chemical company agrees to dispose of the phenol within four years or less, or at the end of the four years to purchase any remainder at such a price as arbitrators may designate. An officer of the Ordnance Department will be assigned to the Monsanto Works to represent the Government in the carrying out of the contract. Preference is to be given to purchasers who intend using the phenol for consumption in the United States. No orders for less than a carload lot will be considered.

FIG. 1. FRONT VIEW OF PITTSBURGH LABORATORIES, BUREAU OF MINES

Description and Activities of the Pittsburgh Station, Bureau of Mines

A New Laboratory Building Costing About One Million Dollars Has Been Dedicated to the Service of the Public at Pittsburgh by the Bureau of Mines — Its Activities Cover a Wide Range of Subjects of Importance to Chemical and Metallurgical Enterprise

By E. E. THUM

DEDICATION of the new Pittsburgh Station of the Bureau of Mines, Sept. 29, was an important milestone in the development not only of this particular station, but of the Bureau as well. Coming at a time when the activities lately so engrossed with war problems are being returned to their normal channels, the provision of such extraordinary experimental facilities promises an equally wide range of future usefulness.

DEVELOPMENT OF STATION ACTIVITIES

Activities such as are now centered in this new station were begun in Pittsburgh in 1908, before the Federal Bureau of Mines was established. This early work was a continuation of the investigative work on coals begun at the St. Louis Exposition, 1904, under the U. S. Geological Survey, the lamented Joseph A. Holmes being chief technologist in charge. A nucleus of instrumental equipment from that World's Fair was installed in the old Butler Street arsenal by arrangement with the War Department. Directed first to the investigation of coal mining problems and of fuels, the chief motive was a desire to guard the miner from the risks incident to his occupation. At the time of the passage of the act establishing the bureau (1910), the factors most effective in calling attention to the need of governmental action were several frightful mining disasters in December, 1907, and a growing realization of the preventable waste of life and resources in the mining and metallurgical industries, later culminating in the "Safety First" movement.

Therefore the statute creating the Bureau of Mines of the Interior Department authorized the new organization to investigate methods to increase health, safety and efficiency in the mineral industries, which being widely interpreted means that the Bureau is enabled to act in many directions all centering upon the conservation of life, material and resources in mining, quarrying, ceramic and metallurgical industry. Having no police powers, the Bureau must translate its findings to practice thorough education, and by co-operation with private corporations or public institutions. With such a wide field of activity, it is also natural that work be segregated at various points geographically well situated with respect to each particular subdivision. Therefore, aside from the general administrative offices at Washington, and important specialized activities at other points, the so-called "stations" of the Bureau now number eleven, as given in the table.

While it is not the present purpose to discuss the work of the Bureau as a whole, the Pittsburgh station is of general interest in that it may be regarded as the parent station, being the headquarters of the Supervisor of Stations, Dr. Dorsey A. Lyon, and having many facilities serving all stations in common. Such a central clearing house is obviously necessary in order to insure the most effective action of all branches among themselves and with the various State agencies working along similar lines, to harmonize activities and avoid needless duplication of effort. Again, although the principal work of the Pittsburgh Station has to do with coal mining, several other cognate divisions are

STATIONS OF THE BUREAU OF MINES
Dr. Dorsey A. Lyon, Supervisor of Stations

Superintendent	Name of Station and Location	Date of Establishment	Scope of Major Investigations	Principal Co-operating Institutions
E. A. Holbrook	Joseph A. Holmes Memorial Station at Pittsburgh, Pa.	1908	Coal mining in all its phases, including mine safety, first-aid, and mine rescue work, testing of explosives also metallurgy of iron and steel.	
C. A. Herbelt (acting)	Middle-West Station at Urbana, Ill.	1908	Coals of the Middle-West fields, and general coal preparation	University of Illinois. Illinois Geological Survey.
Thos. Varley	Inter-Mountain Station at Salt Lake City, Utah.	1910	Complex and low grade ores, especially those of zinc and lead. Concentration problems	University of Utah.
R. B. Moore	Rocky Mountain Station at Golden, Colo.	1910	Rare metals especially. Problems connected with the mining and metallurgical treatment of other ores commonly found in Colorado.	State School of Mines
L. H. Duschak	Pacific Station at Berkeley, Cal.	1911	Metallurgical treatment of the ores common to California (gold and quicksilver).	University of California. Industrial Accident Commission of California.
C. E. Van Barneveld	Southwest Station at Tucson, Ariz.	1916	Metallurgy of the ores common to the Southwest and especially hydro-metallurgical treatment of low-grade copper ores.	University of Arizona. Miami Copper Co.
F. K. Oritz	Northwest Station at Seattle, Wash.	1916	Problems connected with the mining and utilization of the coals of Alaska and the Pacific Northwest; also problems connected with the treatment of the non-ferrous ores of those districts	University of Washington. Oregon Bureau of Mines & Geology. University of Idaho.
J. A. Davis	Alaska Station at Fairbanks, Alaska	1916	The problems connected with the mining industry in Alaska.	
R. T. Stull	Ceramic Station at Columbus, Ohio.	1917	Clay industries and ceramics.	Ohio State University
C. E. Juhlin	Lake Superior Station at Minneapolis, Minn.	1917	The problems connected with the mining and beneficiation of low-grade iron ores, manganese ores, and other ores of the Lake Superior District.	University of Minnesota.
W. P. Dykema	Petroleum Station at Bartlesville, Okla.	1917	Problems connected with the production of petroleum and the conservation and utilization of petroleum and natural gas.	

maintained of much more interest to chemists and metallurgists, and it is important to note that coal mining rescue investigations were responsible for the Bureau's invaluable assistance in developing poison gases for use against the Germans and gas masks for protection against enemy efforts in the same direction. Therefore a description of the station and its activities will doubtless be of general interest.

LOCATION OF NEW BUILDING

The new building itself was planned in a general way by the first director, Dr. Holmes, who early visualized the wide field of the Bureau. It was largely through his efforts that the Forbes street site and the necessary appropriation were secured. Construction of the main building was completed late in 1917. Located on the edge of Schenley Park, flanked on either side by the Carnegie Institute of Technology and the magnificent museum, it is situated in the close vicinity of the center of intellectual and scientific life of Pittsburgh. Thus the resources of the University of Pittsburgh, the Mel-

lon Institute and of kindred institutions are readily available. A front view is given in Fig. 1. Fig. 2 is a view of the buildings from the rear; the central portion is occupied by general and administrative offices, while at the rear is an adequately equipped auditorium capable of seating 240 persons (Fig. 3), available for public use at nominal charges. Laboratories occupy the east and west wings, while in the foreground of Fig. 2 is shown the power house, necessary to house the large-scale combustion or boiler tests on carload lots of various coals. From the front, the main entrance is a massive archway, a monolith in concrete; eagle, decorations and all details forming one great block, to which a special treatment has given a surface accurately imitating granite, altogether a fine and artistic piece of work. An idea of the general interior finish may be had from Fig. 4, which shows the entrance hall and a corridor leading to the west wing, finished in pressed brick and ornamental tile, while the analytical laboratories are furnished with an eye to utility, as shown in Fig. 5.

The central portion of the building is occupied on the ground floor by administrative offices and conference rooms, and the library occupies a portion of the second floor. A mess hall and quarters for the drafting, computing and photography divisions occupy the top. Pittsburgh houses the largest of the seven branch libraries of the main Bureau library in Washington, having some 6600 books and regularly receiving nearly 200 periodicals. Its scope covers physics, chemistry, geology, mechanical and electrical engineering, mining, metallurgy, chemical technology, industrial safety, hygiene, and miners' occupational diseases.

In order to eliminate routine work by investigators, the station has a corps of draftsmen, photographers, computers and clerks, who co-operate with the specialists in the design of special equipment, in the reduction of notes, and in the preparation of data and illustrations for reports. A well-equipped instrument shop is also provided which is manned by tool-makers and glass-

FIG. 2. PITTSBURGH STATION, BUREAU OF MINES; VIEW FROM THE REAR, SHOWING POWER HOUSE, EAST AND WEST WINGS AND AUDITORIUM

FIG. 3. THE AUDITORIUM OF THE BUREAU OF MINES LABORATORIES

blowers capable of building scientific equipment. In addition to routine work of this kind, the photographic department is equipped and manned to take, develop and exhibit motion pictures, thus constituting an important element in the Bureau's educational campaign for promoting safety and health among miners. About 150 reels are now available for public exhibition. The Bureau's equipment is complete for taking films on the surface, within buildings or under ground. Usually, the exposures are made in co-operation with the mine or plant to be pictured, the Bureau furnishing the apparatus, technician and film, while the co-operator furnishes the incidental help and necessary arrangements.

A spacious mechanical laboratory occupies the entire area of the west wing, being two stories in height. During the war it was occupied by a large assortment of physical testing machines borrowed from educational institutions for ordnance work. Apparatus actually belonging to the Bureau is yet somewhat meager; in fact, almost the entire west wing is provided in anticipation of future activities of the organization, as yet unformulated. Considerable space on the top floor is devoted to the investigation and certification of various electrical systems and items of equipment for safe use in gassy and dusty mines.

RESEARCHES ON GAS

Gas investigations and mine rescue work is centered in the basement of the central portion and east wing, with important auxiliary chambers and equipment at the experimental mine, a few miles distant at Bruceton. As before noted, these were the first and yet remain the fundamental investigations of this particular station. While not directly interesting to chemists or metallurgists, it is worthy of note that such work, centering in Pittsburgh for about ten years, gave the Bureau a store of information on suffocating gases which was quickly turned to account in the late war. It is perhaps well known that the Bureau proposed a line of investigation which was eagerly indorsed by the War Department months before we entered the war. Investigations in gas offense and defense were well under way when war was formally declared, and were then carried on for some five months by the Bureau's own resources. Starting from a modest nucleus, by mid-summer of 1917 about 50 experts were engaged in this

work, mostly at American University, Washington, where were early transferred all these activities, and when finally the work was organized as the Chemical Research Division of Gas Defense and taken over completely by the War Department, about 1500 men were intensively studying problems in gas warfare.

Much of the data so secured should be available for industry, and the Pittsburgh station already has work well under way looking toward the application of the Army type of gas mask to industrial uses. Small concentrations of CO, NH₃, SO₂, and finest dust are extremely disagreeable and often quite dangerous if endured continuously, and proper canister fillings for their absorption have already been formulated. Much publicity has recently been given to this phase of the Bureau's work.

METALLURGICAL ACTIVITIES

Metallurgy also has quarters in the basement of the east wing. Eventually, it is planned to center here important investigative work on iron and steel worthy of the volume of the industry in this vicinity, but for several years the work has been limited not only by a lack of funds, but by lack of requisite personnel. For the last three years the press of demand for steel products was so insistent that men of proper caliber were almost entirely engrossed in getting out the production.

Very important laboratory work was done during the war, however, for the district Ordnance Office. In this, the Bureau of Mines acted as host and did all the metallographical work, while physical and chemical testing was done at the station, by enlisted personnel of the War Department. Thousands of tests were made on various classes of metallic ordnance, and detailed investigations of the causes and remedies of certain defects brought to a successful conclusion. For the future of metallurgy at the Pittsburgh station, the present idea is not to establish extensive research laboratories so much as it is to co-operate with existing agencies and corporations in desirable lines of investigation. Thus, in steel, flaky structure and allied defects in alloy steels are still under consideration. An exhaustive investigation of the whole subject of heat-treatment of low-carbon steels is to be started in co-operation with the Bureau of Standards and interested manufacturers, the work probably to be done in Dr. Howe's laboratory

FIG. 4. ENTRANCE HALL

FIG. 5. TYPICAL ANALYTICAL LABORATORY

in Malvern Hills. In iron, a field investigation of factors of blast-furnace operation is under way, paralleling a like study of ferromanganese production which has been completed. Work on slags is also to be continued in co-operation with the committee on blast-furnace slags of the National Research Council.

In non-ferrous metallurgy, aside from the work on brass and bronze, which has been under way for a long time at Ithica (Cornell University), an investigation of foundry practice in aluminum has been started at Pittsburgh. It is hoped to formulate perfected melting and casting methods so that waste and scrapage may be largely reduced, primarily by the reduction of porosity, oxide and gas inclusions. In this connection the relative merits of proposed aluminum alloys will be considered as well as the relation between the quality of ingot metal to the resulting casting.

CHEMICAL LABORATORIES

Chemical analysis occupies the bulk of the first floor of the east wing. The analysis of fuels for use of various departments of the United States Government is one of the chief duties of the analytical laboratory. Many samples of coal, coke, ores and other materials collected incidental to various investigations by the Bureau or co-operating institutions are also analyzed.

FIG. 6. BOMB PROOF FOR TESTING EXPLOSIVES

Here, also, has been under way the extensive researches on the fusibility of coal ash, which will be of much use in determining the liability of any fuel to cause excessive trouble from clinkering.

EXPLOSIVE TESTING

Perhaps the most interesting work being done at Pittsburgh, however, from a chemist's standpoint, is the investigations on explosives under way in the laboratories on the second floor, west wing, and at the testing plant at Bruceton, where all physical tests are conducted. At the latter point is installed equipment for investigating the gases evolved by explosions (most important in metal mining), the "permissibility" of explosives in coal mining, and the rate of detonation (which largely measures the shattering effect), such apparatus consisting of two long galleries, three bomb-proofs, such as shown in Fig. 6, several separate magazines and instrument shelters, a ballistic pendulum, Mettegang recorder (Fig. 7), two impact machines, a pendulum friction machine, flame-testing apparatus, Bichel gages, a calorimeter and a variety of lead block

FIG. 7. METTEGANG RECORDER

expansion and compression test equipment. All the physical characteristics of explosives and different kinds of blasting supplies are here investigated in order that they may be classified so a user may have information on any of the various dangers attending their use, particularly in mines.

Routine analyses of explosives are made at the chemical laboratory, periodically checking the composition of the "permissible" explosives on the market. Much work is also done on purchases of explosives by various Government departments; during the war, especially, the Bureau co-operated with the War Department on grenade fillers, shell fillers, gun greases, and on the proposed substitution of flax and the down of milk-weed, cat-tail and white smoke-root for cotton and for glycerine in the manufacture of nitroglycerine. In the analytical work a continual effort is made to perfect the methods as to speed and accuracy, and much valuable work along these lines has been published. For instance, work is now under way on a modification of the sand test for detonators to give results more nearly proportional to the quantities of priming employed. As is perhaps well known, this test is made by placing an electrically fired detonator in the center of a definite quantity of standard sand contained in a steel block.

After explosion the sand is sifted and the amount of crushing is a measure of strength of the priming; it is also possible to determine whether detonation has been complete.

New explosives are also investigated. Thus, a series of tests on propylene glycol dinitrate as a substitute for nitroglycerine has been completed, as well as much work on a cartridge composed of carbonaceous matter and liquid oxygen.

POWER PLANT

As may be seen from the view, Fig. 2, advantage has been taken of topography to place the powerhouse on a low level, behind the main building and out of sight from the front. It is a reinforced-concrete structure 55 by 220 ft., divided into three parts. At the west end is the fuel-handling equipment and three watertube boilers. In the center of the building are installed the engines and electric generators, while the space at the east end is destined for apparatus for the study of heat transmission through boiler tubes, the study of combustion process within the fuel bed, and of problems of efficiency in domestic heating equipment of all sorts. Investigations of this sort are in charge of the fuel-efficiency section of division of fuels and mechanical equipment, and have rendered great service to other governmental bureaus in matters pertaining to fuel economy, and led to the issuance of publications that are believed to be of greater usefulness than those previously available.

Observations Regarding Chlorine Cells

By F. G. WHEELER

IN THE operation of all chemical machinery, questions regarding the various forms of construction and the best methods of operation are of prime importance to the engineer. This is particularly true of the electrolytic alkali industry, where many varying conditions in the application of the process exist. To answer some of these questions, the writer has experimented for many years, and has investigated many phases of this process. The results of these experiments have been embodied in several plants which are working on a large commercial scale today.

The most prominent questions which were solved were those regarding the efficiency of a cell, the overload capacity, the influence of temperature, the problem of feeding a cell constantly with brine, the impregnation of anodes, and the many conditions governing cell operation.

The type of cell which the writer adopted is one the form of which was first used by James Hargreaves in 1894. It was later developed by James Mercer and put into practical operation at Haverhill, Mass., in 1898. It was also used by Merry and Noble in England and later by Arthur Gibbs in the United States. The cell is cylindrical in form and built so that the entire exterior surface is cathode. Like a drum, it is able to withstand pressure from within without bracing and without distortion. This form of cell has been adopted by several of the largest electrolytic alkali manufacturers, and there are undoubtedly more cells of this type in operation than any other one form, and possibly all forms combined.

The cylindrical shape has the advantage of requir-

ing no joints except those at the ends, which are held tight by means of a hoop. As a barrel is one of the cheapest forms of package, this form of cell is the cheapest to build. It adapts itself with the greatest ease to the many varying conditions which arise and is remarkably successful from a commercial standpoint.

The efficiency of a cell, by which we mean the proportion of product made compared to the amount of electricity used, was early observed by Hargreaves to be a function of the strength of liquor delivered, that is, the lower the percentage of hydroxide in the cathode liquor, the higher the efficiency. Hargreaves concluded that it was impossible to produce caustic soda with an electrolytic cell because of this action of the concentrated caustic soda. He fully understood the fact that if brine were passed through a diaphragm in contact with a perforated sheet of metal, which was made the cathode of a cell, and if one-half of the brine or less were converted to caustic soda, an efficiency approximating unity was easily obtained. He also used the idea of adding steam to the empty cathode compartment in order to wash the caustic away from the cathode to prevent the hydroxide ions from migrating into the anode solution. His idea, however, was to make a pure product in the cell, and he did not consider the manufacture of a solution of caustic soda mixed with salt and purifying it for commercial use.

THE DIAPHRAGM PROBLEM

In our first experiments, we found that the caustic could be washed away from the cathode by using a very thin diaphragm which was very easily permeable to the brine. In the commercial operation of a cell, the diaphragm becomes plugged, not only with the impurities which might escape the filters, but with those made in the cell itself, such as disintegrated graphite, and from the action of the liquor on the diaphragm itself. It is obvious from this that the thinner a diaphragm can be made, the more slowly will it become impermeable. It is also apparent that the thinner it is, the less capillary action is present to hold the caustic soda solution between the two electrodes after it has once been formed.

The problem of making cheaply a very thin diaphragm is one of using a cathode which will hold such a diaphragm in position. The idea of supporting a diaphragm with the cathode is an old one and was used first by Hargreaves, and mentioned in his patent of Dec. 28, 1897. To apply this principle, a cathode was first designed using two sheets of metal. The inner sheet was a thin sheet having large perforations, and the outer was a heavier one having fine perforations. The idea was to place a thin sheet of asbestos paper against the inner sheet of the cathode. When it would attempt to burst through the large perforation of the inner sheet due to the pressure of the brine from within, the outer sheet would prevent its rupture, yet would still allow the products of electrolysis to be removed from the field of reaction.

A double cathode of this type is expensive to build and difficult to handle, so that a single sheet was devised which had all of the advantages of the double sheet. This cathode is made by displacing the metal removed from the large perforation backward, but not detaching it from one edge, leaving the flap in such a position that it prevents rupture of the diaphragm, but still leaves a three-sided perforation for the removal of the products of electrolysis.

A cell with this cathode is so designed that the edge formed in each large perforation is not thick enough to cut the diaphragm, yet at the same time the sheet of metal is heavy enough to conduct the current economically. These properties have been ascertained, so the construction of a commercial cell is simple.

Cells built as described have an efficiency approximating unity over long periods of time, and plants are now operating with a commercial efficiency of over 95 per cent with no difficulties from diaphragms or cathodes.

Many industries require cells which can be shut down without damage, so this question was carefully examined. The usual difficulties connected with shutting down a cell arise from changes of temperature and also changes in the delivery of the hydrogen gas. The caustic soda which is formed on the cathode passes with the hydrogen gas through the openings in the cathode and is discharged into the cathode chamber. When a cell is shut down, the evolution of the hydrogen ceases, together with the consequent reducing action of the nascent hydrogen at the cathode. The diaphragm is then pressed against the cathode by the brine in such a way that the tiny passages which have been occupied by hydrogen are closed. The chlorine in the brine is not reduced by the nascent hydrogen evolved at the cathode during operation, but attacks the metal, forming ferric chloride. This passes with the brine into the cathode compartment of the cell. A small amount is retained in the diaphragm by capillary action. When the current is again started, the caustic soda, which is first formed, changes the ferric chloride into gelatinous ferric hydroxide, which partially plugs the diaphragm. The hydrogen formed simultaneously with the caustic soda has no easy method of egress or open passages, but must force its way through the pulpy diaphragm until it reaches the nearest opening in the cathode. The cells, therefore, do not deliver the caustic after a shut-down as easily as they did before. As the cell becomes warmer, the viscosity of the brine decreases so that it flows through the diaphragm more readily, the ferric hydroxide is slowly removed by the brine, the hydrogen creates passages to the nearest openings, and the cell returns to its previous operating condition.

EFFECT OF STEAM TREATMENT

The effect of steam, which is blown into the cathode compartment, was tested with various results. As predicted by Hargreaves, the steam dilutes the caustic soda on the cathode, and in this way helps to keep the efficiency of a cell high. The condensation of the steam on the jacket is easily cared for by trapping it away from the cathode liquor, so that this steam does not dilute the solution, but the condensation on the cathode itself has to be re-evaporated in the concentration department. The steam keeps the cell hot, lowers the viscosity of the brine, causing it to flow more easily through the diaphragm, reduces the concentration of the hydroxide ions, increasing the efficiency. A cell was operated for several months at an efficiency so close to unity that the difference could not be found by ordinary experiments. Cells which were old and worn out, and had been impermeable to the brine, were treated with steam and responded as mentioned above, the efficiency being increased somewhat, but the cost of renewal of a diaphragm is so small, about \$3, and the additional cost of reconcentrating the solution so high, that no real advantage is gained.

The question is simply a commercial one. If power is expensive, it may pay to use steam to save power, but where the power is cheap, the question would be an entirely different one.

RATING OF CELLS

Many cells are given a normal rating, which is described as being so many amperes. The writer often wondered upon what facts this capacity rating was based. Accordingly, an experiment was tried in which a cell was subjected to an enormous current with the hope of learning what would happen when an excess of current was passed through the cell. A cell was selected which would carry 750 amp. at 3.5 v. By means of an experimental generator, an additional current was superimposed upon the regular current, with the result that this cell carried 2300 amp. at 4 v. Unfortunately, the experimental generator could not be operated at a higher current, but the experiment was continued, with the result that at the end of four weeks two cells, which had been carrying 2300 amp. for this length of time, were delivering 93 per cent of the theoretical amount of caustic soda. We naturally concluded that there was no specific rating for any cell. If power is cheap, it is obvious that it does not pay to install a large number of cells and work them at a low current. The interest and depreciation on the cells will more than offset the power which is saved by operating these cells at a low voltage, and it therefore pays to use a higher voltage and pass a higher current. The whole question was worked out very carefully, numerous curves were drawn, and it was found that a minimum cost could be easily ascertained when local conditions were considered.

FEEDING DEVICE FOR SUPPLYING BRINE

Another phase of the subject is the method of supplying the brine to a cell. A successful feeding device must be one which has in it several important features. In the first place, it must be foolproof and require practically no attention when once started. It must maintain the level in the cell automatically, so as to keep conditions constant. It must be totally enclosed, so that no evaporation of brine will cause salt to crystallize in the feeding device. It must also have no constriction, nor can it be made to operate by means of a small aperture, for in any such device a particle of dirt, salt, or even an air bubble will cause it to fluctuate in the quantity of brine delivered. It must be cheap to construct. It must not allow any electrical current to flow through the brine being fed to the cell, because this to some extent grounds each cell and causes "electrolysis" in the pipe lines and other metallic parts of a plant. Bearing all of these things in mind, a feed was devised which delivers a broken stream through an enclosed piece of apparatus, in which there is no throttling effect and the quantity of brine delivered is controlled by the level in the cell itself. It consists in passing the brine through a chamber of gas. The gas in the chamber is held under a certain pressure due to the level of the brine in the cell, and this pressure regulates the brine being admitted to the chamber.

PROBLEM OF ELECTRODES

A very interesting experiment was made in connection with the preservation of graphite anodes. The first idea was to fill the pores of an anode with an

inert material, which would prevent the current from detaching particles of graphite. In this way the anode would have a much longer "life" than without this treatment. The graphites were first impregnated with various oils. It was soon found that the excess of oil in the pores of the graphite was discharged and floated on the surface of the brine, then chlorinated, forming a wax. This prevented the chlorine from escaping from the cell, and caused trouble.

A method was devised in which the inside of each pore in the graphite was painted with an inert liquid, in such a way that the wall of the pore only would be covered. There was no excess of oil to be discharged from the graphite after it had once been treated. After this problem was solved, almost every kind of oil was tested. Not only the common oils, but such material as vulcanized oils and mixtures with asphalt and pitch were used. A good selection was finally made and thoroughly tried out. The question of impregnation resolved itself into one involving the cost of power. It seems that impregnation not only saves graphite by making the inner surface of the pores resistant to the chlorine, but it also presents a smaller surface for the electricity, in passing from the anode. The increase in the current density on the graphite is shown by an increased terminal voltage on the cells, with the result that an anode which has been impregnated requires more power per ton of product than a cell in which the anodes have not been impregnated. The problem becomes one of choosing whether the cost of impregnation plus the cost of power is cheaper than the cost of graphite. Where power is cheap, it pays to impregnate.

CONCLUSION

When a cell is constructed according to the principles which we have described, with a good feeding device, with the graphite either impregnated or not according to local conditions, made so that it will work at a high temperature, and with the proper local conditions taken into consideration, there is little difficulty in making a plant deliver caustic soda and chlorine at almost any efficiency desired, and at a voltage which will net a handsome profit even under some of the most difficult conditions.

Bureau of Foreign and Domestic Commerce Publishes the First of Its Educational Series

"Selling in Foreign Markets," by Dr. Guy Edward Snider, of the College of the City of New York, has just been published by the Bureau of Foreign and Domestic Commerce. This is a collection of readings of some 600 pages, covering in a logical and co-ordinated manner various phases of marketing American products abroad. The new movement in education for foreign trade, the keynote of which is the unit short course dealing with some specific phase of the subject in a detailed and concrete manner, disclosed the fact that literature of a specific nature is lacking. There has been a great deal published for general reading in foreign trade, but little has been written specifically for college work. The Bureau of Foreign and Domestic Commerce, in co-operation with the Federal Board for Vocational Education, is extremely desirous of having introduced into educational institutions, including reading circles, a type of foreign trade study as is supplied in its publication "Selling in Foreign Markets."

Synopsis of Recent Chemical and Metallurgical Literature

Stainless Steel.—The literature relating to this interesting alloy is exceedingly meager. Two contributions have been made recently, however, which throw some light upon the history and properties of this alloy, although the chemical composition is not disclosed.¹ Stainless steel was discovered in the research laboratories of Thos. Firth & Sons, Ltd., Sheffield, by Harry Brearley, while working on armor piercing projectiles for the Russian Government. It was soon found that the new alloy did not scale easily and did not tarnish when exposed to the action of many acids, including fruit acids. This suggested its use in the cutlery trade. R. F. Mosley's cutlery works was the first to use it for this purpose. The alloy is not protected by patents in England, but the foreign patents are controlled by the Firth-Brearley Stainless Steel Syndicate, with the exception of the American patents, which were sold to a co-operating body of large steel makers, the American Stainless Steel Co., of Pittsburgh. (U. S. P. 1,299,404, granted to Elwood Haynes on Apr. 1, 1919, and assigned to this company, relates to a chromium-iron alloy containing 20 to 25 per cent Cr and 0.1 to 0.5 per cent C, which is claimed to be practically permanent against fruit acids, exposure to air and rain, etc.).

This steel is capable of attaining, by suitable heat treatment, a wide variation in mechanical properties up to extreme hardness. It does not scale appreciably under 800 deg. C., while its tensile strength is not materially reduced at 400 deg. C. This property, in combination with the resistance to erosion, led to the use of the alloy for the manufacture of exhaust valves for airplane engines. Among other engineering applications of the alloy may be mentioned: Turbine blades, pump rods and valves, acid pumps, rams, cotters, evaporating pans, races and rollers for bearings, steam traps, etc. Since the steel is unaffected by salt water or sea air, it may be employed for a variety of marine purposes. In the electrical field, stainless steel is used for permanent magnets and for electric cooking stoves and utensils, where the advantages of permanently bright and clean surfaces in assisting the reflection of heat and consequent economy of current are immediately apparent.

A New Process for the Synthesis of Ammonia.—The Hampel-Steinau process for the synthetic manufacture of ammonia is described in the Dec. 18, 1918, issue of the *Technische Rundschau*. The examination of the patent previous to issue, by the German patent office, shows the principle to be completely new. In place of using a catalyzer to increase the velocity of combination of nitrogen and hydrogen, Hampel-Steinau utilize the properties of nascent hydrogen, combining it with nitrogen as it is in the act of being formed. The nascent hydrogen is produced by the action of chemical compounds on suitable metals, a large choice of detail being possible in this respect.

In the preferred form of the process, ammonium chloride acts on iron to produce the nascent hydrogen. It is well known that at 250 to 300 deg. C. ammonium chlo-

¹"Story of Stainless Steel," *Iron Age*, July 31, 1919, p. 294 (taken from the *Organizer*, a British monthly); "Firth's Stainless Steel," *Electrician*, July 25, 1919, p. 97.

ride splits up into NH_3 and HCl . If iron is present, the HCl acts on the iron to produce hydrogen, thus furnishing the nascent hydrogen for the process. If nitrogen (made from liquid air) is also present, it unites with the hydrogen to produce NH_3 . The iron chloride formed is brought into solution, and precipitated by part of the NH_3 , enough being used to re-form the original quantity of NH_4Cl .

The reactions described may be thus set down:

The first three reactions, being in reality simultaneous, may be written thus:

Six of the eight molecules of NH_3 are used to regenerate the NH_4Cl , leaving a gain of 2NH_3 , while the iron hydrate precipitate is filtered out, dried, and treated by reducing gases to regenerate the iron powder. The whole process is thus a circle, with only water and nitrogen coming in and NH_3 coming out.

The process goes on smoothly in the particular apparatus which has been devised for it. With 50 atmospheres pressure and at about 300 deg. C., the gas mixture obtained is 98 to 99 per cent NH_3 , of which three-quarters goes back into the process for precipitation of the iron salt, leaving 23 to 24 per cent of the ammonia as clear gain. The apparatus is only slightly attacked, and no ammonium chloride is lost.

The nitrogen needs to be prepared, as in other processes, but not the hydrogen. The gas obtained is 98 to 99 per cent ammonia. The advantages of the process appear to be numerous.

Recent Chemical and Metallurgical Patents

Complete specifications of any of the United States patents may be obtained by remitting 5c. each to the Commissioner of Patents, Washington, D. C.

Rare Earth Oxide Ceramic Structure.—The increase of electrical conductivity with increase in temperature shown by ceramic materials containing silicates, such as porcelain, earthenware, etc., is explained by the theory that devitrification of fused silica is due to depolymerization of large silica molecules, giving a greater number of charge-carrying bodies. On the basis of this assumption, CHARLES KNOX HARDING of Chicago has studied the possibility of producing insulating ceramic materials free from silica. He has found that the neutral tri-valent and tetra-valent earth oxides, such as lanthanum, thorium, zirconium and didymium, are especially suitable for this purpose. They may be obtained from monazite sand. As an example, finely ground calcined lanthanum oxide with air dry lanthanum phosphate and 6 to 12 per cent gelatinous lanthanum hydroxide may be subjected to a high pressure in a metal die and formed into a very compact structure which will not check in air drying and which may be fired to a very high temperature (above Seger cone 20) without injury. (1,296,076; Mar. 4, 1919.)

Metallic Magnesium From Magnesium Oxide.—Attempts to produce magnesium by a method similar to that used for aluminum have been unsuccessful,

owing to the slight solubility of the oxide in the double fluorides of magnesium. GEORGE O. SEWARD has found that triple fluorides of magnesium, barium and sodium, such as MgF_3 , BaF_3 , NaF (sp. gr. 3.22), have specific gravities so nearly approaching that of magnesium oxide (3.66) that the bulk of the latter will remain in suspension in the molten bath. Some of the oxides floats on the surface, thus preventing the escape of free fluorine and at the same time protecting the anodes from "necking in" by oxidation just above the electrolyte. Although the oxide dissolves to the extent of only 0.1 per cent in the bath, the oxide in solution is replenished as electrolysis proceeds by the large excess of oxide in suspension. It is also possible to use magnesium carbonate, as this calcines quietly to the oxide, while floating on the bath. The cell is similar to the modern aluminum furnace. Molten copper is used as cathode, since it forms fusible alloys with magnesium but does not readily alloy with sodium. The working temperature is about 950 deg. C. and the current density 400 amp. per sq.ft. of cathode surface. (1,310,449 and 1,310,450; assigned to American Magnesium Corp.; July 22, 1919.)

Electric Furnace Electrode.—MARK SHOELD of Chicago, Ill., has devised an electric arc furnace electrode which is capable of being built in larger sizes than is at present practical, by combining seven small cylindrical electrodes into one unit. This arrangement has several advantages: an accident to one element will not seriously interfere with the furnace operation; the current density is reduced because of the larger surface area; the individual elements are less prone to damage caused by the warping and twisting stresses. (1,313,126, Aug. 12, 1919; assigned to Armour Fertilizer Works, Chicago.)

Clay Binder and Process for Making Same.—HENRY L. KOHLER of St. Louis, Mo., improves the quality of fire-clay brick and makes possible the manufacture of brick from clays which do not in themselves contain sufficient bonding properties. This is accomplished by adding from $\frac{1}{2}$ to 5 per cent of anhydrous aluminum sulphate to the finely pulverized clay, which has been previously mixed with a certain amount of water. The aluminum sulphate crystallizes by combination with this water and thus acts as a temporary binder, making it possible to mold the product. In the molded product, after standing for a sufficient length of time, the aluminum sulphate reacts with aluminum silicate, forming basic aluminum sulphate and silicic acid. Upon burning, the sulphates are converted into oxides and the silicic acid into aluminum silicates, these acting as binders. The products are more resistant to disintegration caused by temperature changes and a larger percentage of perfect brick results from this method of manufacture. (1,312,853, Aug. 12, 1919.)

Electric Furnace.—JAMES H. GRAY of New York City designs the tilting device of an electric furnace so that the center of rotation is near the top of the furnace roof. This arrangement permits of supporting the electrodes and cooling rings from above by means of cables. The electrodes are thus held stationary while the charge is being poured, and are thereby relieved of the strains produced when the electrodes are tilted with the furnace. The mechanical details of furnace construction are simplified, because it is not necessary to design the furnace to support the weight of the electrodes, cooling rings

and their appurtenances. The design is of particular advantage when large currents are supplied at low voltage; the large sized flexible conductors required to carry the current are much shorter than in the usual design. (1,313,890, Aug. 26, 1919.)

Oxalic Acid From Paper Mill Waste Liquors.—Waste liquor is evaporated so that a dry or semi-dry residue is obtained. This is mixed with four times its weight of caustic alkali and heated in thin layers for 6 hr. at 250 deg. C. Sufficient water is added to dissolve the excess alkali and soluble organic material, leaving sodium oxalate in the residue. A second leaching with fresh water dissolves the sodium oxalate. From this solution, oxalic acid is recovered in the ordinary manner by precipitating calcium oxalate and decomposing this with sulphuric acid. (1,310,713; HERBERT C. REED of Stamford, Conn.; July 22, 1919.)

Use of Trinitro-Nitranilid and Sulphocyanates in Primers.—In place of mercury fulminate, WILLIAM H. BUELL proposes to use 2,4,6-trinitro-nitranilid, $C_6H_3(NO_2)_3NHNO_2$, with potassium chlorate, antimony sulphide and sulphocyanates of lead, copper, etc., in the proportion of 10, 50, 15 and 25 parts by weight, respectively. (1,311,872; assigned to E. I. du Pont de Nemours & Co.; Aug. 5, 1919.)

Annual Sample Fair at Barcelona

There has recently been organized in Barcelona a corporation under the title of "Feria de Barcelona, S. A.," with a capital of 500,000 pesetas (\$100,000), for the purpose of holding annual sample fairs similar to those of Lyons, Bordeaux and Leipzig. The mayor of Barcelona will be president of the executive committee. Preparations are under way for holding the first fair during the spring of 1920.

Book Reviews

THE JOURNAL OF THE INSTITUTE OF METALS, Vol. XXI. Edited by G. Shaw Scott, M.Sc., Secretary. 508 pages. London: The Institute, 36 Victoria Street, Westminster, S. W. 1.

This volume, one of the most important if not the largest yet published by the Institute of Metals, contains the lengthy "Fourth Report of the Corrosion Committee," by Guy D. Bengough and O. F. Hudson. After a brief consideration of current theories of corrosion, the authors present the result of their own detailed experimentation on the corrosion of zinc, copper, aluminum and brass, this part alone occupying over 100 pages of text. Next follows Part II, on the corrosion of condenser tubes, which was briefly abstracted in CHEMICAL & METALLURGICAL ENGINEERING for June 1, 1919, p. 594. Finally, the authors conclude with 15 pages of notes on the practical aspects of the corrosion problem, such as the effect of scale, methods of electrolytic protection, and other methods of hindering corrosion. Altogether, with discussion, this report occupies some 250 pages.

It is safe to say that this report is by far the most important publication on corrosion which has appeared in the last five years, and consequently the volume will be found indispensable to all students of this most important waste in metallic materials. In addition to the corrosion report, this volume of the Journal contains its usual array of authoritative papers on non-ferrous metallurgy, such as micrography of aluminum and its alloys, and the effect of work on various alloys. Fifty pages of abstracts of the literature complete the volume—a feature in itself which is of great importance.

E. E. THUM.

Obituary

Dr. E. G. LOVE, treasurer of the American Chemical Society, former president of the Chemists' Club, and for a long time chairman of its house committee, died Friday evening, Sept. 12, from surgical shock following an operation. He was 69 years of age. He was a graduate of Hamilton College and of Columbia University, and in 1877

Copyright, Underwood & Underwood

DR. E. G. LOVE

was made gas examiner for the City of New York. For many years he maintained a laboratory in New York City, and several years ago was made chief chemist for the Consolidated Gas Co. Dr. LOVE was very well known among the chemists of America, and had been active at meetings of chemical bodies for many years. He was a man of rare popularity.

Personal

Dr. L. H. BAEKELAND, honorary professor of chemical engineering in Columbia University, has been decorated by King Albert with the Order of the Crown of Belgium.

Major F. E. BREITHUT, Chemical Warfare Service, has been honorably discharged from the Army. Dr. Breithut has resigned as assistant professor of chemistry at the College of the City of New York to take a position with the Foundation Oven Corporation, Woolworth Bldg., New York City.

Mr. H. K. DAVIES, formerly with Wallace & Tiernan Co., Inc., of New York City, has recently entered the employ of the Pennsylvania Salt Manufacturing Co., Widner Bldg., Philadelphia, Pa., for the purpose of developing the use of liquid chlorine.

Mr. CHARLES U. GEESEY, engineer of tests and metallurgist, U. S. Ordnance, during the war and formerly with the Gary Works of the U. S. Steel Corporation, has joined the executive force of the Garford Motor Truck Co., Lima, Ohio, as chief chemist, metallurgist and adviser to the heat-treatment department.

Mr. H. E. HARING, for the last two years in the inspection division of the Ordnance Department, is now connected with the Bureau of Standards, where he will be engaged in electrochemical research.

Dr. CHARLES L. PARSONS, chief chemist, has tendered his resignation from the Bureau of Mines, to become effective Nov. 1. On that date he will open an office in the Mills Building annex at Washington, D. C., where he will conduct the Washington office of the American Chemical Society and in addition will do private work.

Prof. J. W. RICHARDS, Lehigh University, South Bethlehem, has returned to the United States after spending the summer in Denmark, Norway and Sweden.

Dr. THEODORE W. RICHARDS, professor of chemistry at Harvard University, has been elected president of the American Academy of Arts and Sciences.

Mr. EDGAR S. ROSS, formerly chief chemist for the Charlotte Chemical Laboratories and Columbite Reduction Co. of Charlotte, N. C., is now located at New Hampshire College, Durham, N. H., where he will carry out special research in the rare earths in conjunction with Professor C. James.

Major General WILLIAM L. SIBERT, director of the Chemical Warfare Service, U. S. A., has been made a commander of the French Legion of Honor.

Prof. ALEXANDER SMITH, head of the department of chemistry at Columbia University, was granted on July 10 the honorary degree of doctor of laws by the University of Edinburgh.

Lt.-Col. C. G. STORM, Ordnance Department, U. S. A., chief of the Research Section, Ammunition Division, has been honorably discharged from the service and is now engaged in research work with the Pennsylvania Trojan Powder Co., Allentown, Pa.

Dr. J. P. STREET, chemist in charge of the analytical laboratory of the Connecticut Agricultural Experiment Station, and recently major in the Sanitary Corps of the U. S. Army, has been assigned by the National Cannery Association as chief inspector for the State of Indiana.

Current Market Reports

The Non-Ferrous Metal Market

Tuesday, Sept. 23.—Pending the restoration of normal conditions in the steel industry, little business is being transacted in the non-ferrous metal market.

Aluminum.—The market remains quiet, with 98-99 per cent ingots at 33c. per lb. There is a fair demand for scraps; cast, 21½-24½c.; sheet, 21-23½c.; clippings, 23½-27½c.

Antimony.—The market is quiet; spot wholesale lots being offered at 8½c. and job lots at 8½-8¾c.

Copper.—Reports indicate favorable prospects for a buying movement when the steel situation is relieved. Spot and September are quoted at 23½c. lb., October and November, 24c.

Copper sheets, hot-rolled.....	lb.	33 50	—
Copper sheets, cold-rolled.....	lb.	35 00	—
Copper bottoms.....	lb.	41 50	—
Copper rods.....	lb.	24 75	—
Copper wire.....	lb.	27 25	—

Scrap, No. 1 clean brass turnings.....		1½	— 10½
Scrap, No. 1 comp. turnings.....		16½	— 16½

Lead.—The market is firm, spot New York being 6.07½-6.25c. and East St. Louis, 5.85-6c. lb.

Tin. London reports indicate a further decline. Straits spots are quoted on the New York market at 55c., with 99 per cent electrolytic at 54½c. lb.

Zinc.—The falling off of the demand from the steel companies caused a further drop in price. Spot New York, 7.30c. lb.; October, 7.35c.; November, 7.37½c.; December,

7.40c. East St. Louis spot, 7.00-7.05c.; October, 7.10c.; November, 7.15c.; December, 7.17½c.

The Iron and Steel Market

The iron and steel markets were more or less influenced during August and the fore part of September by threats of a strike in the industry. Since the strike began Monday, Sept. 22, there has been no distinct market situation, the strike being the sole item of interest.

The strike may be described from several different angles as follows:

(1) It is a strike of common labor almost wholly. Of the common labor the strikers are mainly the foreign born, as it was only to them in their ignorance that a strong appeal could be made by the agitators.

(2) It varies in intensity in districts, in the order of intensity approximately as follows: Wheeling, Youngstown, Calumet (Chicago and Gary), Lake Erie front, the Pittsburgh district, the South, the East. There is practically no strike east of Johnstown, Pa., and Buffalo, N. Y., while the Cambria and Lackawanna plants, respectively, at those points are closed completely.

(3) It affected the Steel Corporation and independents about equally, but as the East did not strike and is wholly independent, the remainder of the industry showed more strike for the independents than for the Steel Corporation.

(4) The strike being of common labor, it affected plants making various products in about the same proportion.

After a careful scrutiny of reports covering practically all points it may be estimated that the strike closed about 35 per cent of the productive capacity. The curtailment in output was greater than this, because in the matter of a strike it is not tonnage output that counts, but employment. As long as a plant is operating it counts against the strikers, because men are working in it, whether or not the output is in proportion to the number of men working.

On the whole, the strike was not altogether as extensive as the manufacturers expected, in case the strike call were persisted in at all. The strike order was issued Sept. 10, for Sept. 22, but in the interim there was almost continuous doubt as to whether or not the order would be recalled. It is not certain, however, that the strike disappointed the agitators, who, by their conduct beforehand, had given many inklings that they were doubtful of being able to produce a strike of any magnitude. That they would call a strike when such doubt existed is not strange, for they knew one thing quite well, that their chances of success were at the peak. They had produced a certain amount of excitement and unrest among the men and had no means of maintaining the excitement. This could be done only by an active force. The excitement did not tend to maintain itself, but would die out if not nurtured. It was a species of mob psychology, in which these labor agitators are fairly well versed or they would be unable to agitate.

Being of common labor, the strike affected blast-furnaces more than steel works, where the works were operated in conjunction, but by reason of so many merchant blast-furnaces being scattered, and largely free from strike on that account, there is more or less of an even break between the proportion of steel capacity and of blast-furnace capacity affected. In the Mahoning and Shenango valleys, where merchant furnaces are close together, there were few that did not have to bank.

The districts did much as was to be expected. The Wheeling district has always been strong for strikes, and some of the plants were closed by the managements in advance, it being fully realized that a strike would occur. Almost the entire district was idle the first day of the strike. Youngstown was closed practically tight within a day or so. Youngstown will be remembered as

the scene of riots early in January, 1916, so the district ran true to form.

The Connellsville coke region was not touched by the strike. The by-product plants at Youngstown were closed, but the Farrell plant remained in operation, and the great Clairton plant operated better than 50 per cent. With so many furnaces banked a surplus of coke developed and Connellsville operations had to run fewer days per week, with a possibility that some ovens would have to be put out entirely. The lake ore boats were able to leave with full crews, but it was not certain that the condition would continue.

As soon as the general scope of the strike could be gaged with some accuracy the conclusion was reached that the question whether the strike would grow or diminish would be determined by the Monongahela Valley. That valley did not escape altogether, the two independent steel plants at Monessen being closed at the outset and the Braddock and Rankin wire plants within a day or two. The three great Carnegie works, Homestead, Edgar Thomson and Duquesne, however, escaped almost entirely, except for a few blast-furnaces; Clairton operated in part, and the great National Tube Works at McKeesport escaped entirely. It was expected that if the Monongahela Valley could be kept in operation to the extent that obtained the first two days of the strike there would eventually be a yielding of the strikers at Youngstown and then a yielding even as far away as Gary and Chicago. At this writing the prospects are that the Monongahela Valley will hold. The agitators at once concentrated their efforts on Homestead, but without making any inroads beyond the slight defections that occurred at the outset.

The iron and steel manufacturers held no meetings in advance of the strike and needed none to become of one mind, for the issue was too plain to admit of doubt or debate. It was purely one of surrender of control of the plants to professional agitators. The manufacturers will contest the issue until they have won. How long or how short the contest will be no one has ventured to predict. Professional strike breakers will not be employed. Undoubtedly many of the men who are out are out because of intimidation and the number of such will doubtless grow. There have been numerous clashes between strikers and would-be workers, but the arrangements of State, county and municipal authorities have been extensive and are probably adequate for the preservation of order, though possibly not for the return of men to work, unless such men are very largely in the majority. The time may come when strenuous measures will be necessary to protect men desiring to return to work.

The organization campaign did not produce strike funds, as the small sums collected from those who "joined" would barely pay running expenses. Some of the 24 unions under whose auspices the movement was conducted may have large strike funds, but the money would not be used except to support members of the respective crafts, and thus such funds scarcely count at all. Many of the common laborers, and it is claimed the great majority, are relatively well provided with funds, running into hundreds of dollars apiece. The manufacturers are of course in position to conduct a strike indefinitely, as the time is long past for iron and steel manufacturers to be short term borrowers. The chief hardship, and a very great one, in a prolonged strike, would fall upon the consumers of steel. Many buyers of steel have been quick to advise the steel producers from whom they draw their supplies that they are in full accord with the manufacturers' position and will uncomplainingly submit to any hardships the situation imposes.

The Chemical Market

New York, September 22.

Business in this market, on the whole, is good; in some branches it is excellent. Belonging in the latter class are industrial chemicals and coal-tar intermediates. While the sagging condition of foreign exchange has had a deterrent effect on export trading, business of proportions

yet emanates from that source. Fairly representative of conditions in the chemical field is the statement of an important manufacturer that last month was the biggest month he has had in two years, and that he is sold ahead for the next two months on practically all his products. As against the weakness in crude rubber and naval stores, the vegetable oil market is apparently becoming stronger, due to the fact that speculative interests are now buying to cover previous losses, while soap manufacturers have run low in supplies and are anxious buyers.

The influenza scare which is sweeping the country again is having the effect of bringing out very strong demands for formaldehyde, which is held at 22c. per lb. minimum. Leading makers are sold in advance four weeks to two months. There is also a sizable outlet through export channels.

There being a present slight shortage of *aqua ammonia*, with demand increased, a strengthening inclination is apparent, although no change in price has been announced.

Demand for salt cake (*sodium sulphate*) has not diminished since the last review. With several producers having their output for the remainder of the year taken, there is a slight shortage. One manufacturer has advanced the quotation to \$21 per ton, but this increase is by no means general.

Unabated demand keeps the heavy acids, particularly *muratic* (*hydrochloric*), in short supply. South America and Cuba have been buying heavily of these acids for some time, as well as *aluminum sulphate*. Lack of demand, on the other hand, has sent *tartaric acid* down to 79½c. per lb. from 84-86c. An export interest in *picric acid* has sprung up recently with the Far East and South America the principal buyers.

The majority of producers are allotting only small quantities of *barium chloride* to their customers, this being another of the chemicals whose production is covered—in some cases to the end of the year—by advance sales.

Similarly affected by the conditions of shortage and demand are *sodium nitrate*, *sodium prussiate*, *yellow*, both the red and yellow varieties of *potassium prussiate*, *alcohol* and *refined gum camphor*. On practically all of these items manufacturers are behind in deliveries. Gum camphor has received a sharp advance of 10c. per lb., to \$3.30, with the bigger interests seemingly having dropped out of the market.

Manufacturers are still holding *sodium tichromate* at 15c. per lb., although now and then a few lots are offered at 14½-14¼c.

COAL-TAR PRODUCTS

Some manufacturers of coal-tar intermediates, having their production for the remainder of the year already sold, are buying themselves with placing contracts for next year. Still the prominent feature of this market is aniline oil. It is very scarce at 32c. per lb. for spot, an advance of 2c. over the bottom selling figure two weeks ago. Future deliveries into next year are offered at 26c. Aniline salt is in the same strong position with spot material quoted at 35c. minimum, in comparison with 28c. which obtained at the last writing.

The Government restriction on the export of its surplus phenol, together with the cost entailed in re-working material purchased from this source, has led to an advance by manufacturers to 15-16c. in drums for the U. S. P. grade.

Metol, a photographic developer, is again on the market, selling at \$11 per lb. It is another of the German-made products on which chemists have been experimenting during the war and which now can be produced in sufficient quantity for commercial use.

VEGETABLE OILS

Domestic business is holding most of the interest in vegetable oils, the bulk of the buying coming from speculative interests and soap manufacturers. Export commerce shows some improvement and is only awaiting exchange adjustments before accruing to former proportions. Germany and Austria are negotiating for large quantities of vegetable oils through indirect sources.

Paraffine wax, refined, 133-135 m.p.	lb.	.11	—	.11
Paraffine wax, refined, 135-137 m.p.	lb.	.12	—	.13
Stearic acid, single pressed.	lb.	.25	—	.26
Stearic acid, double pressed.	lb.	.27	—	.28
Stearic acid, triple pressed.	lb.	.30	—	.33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls. gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.	gal.	\$1.05	—	
Pine oil, pure, dest. dist.	gal.	.96	—	
Pine tar oil, ref., sp. gr. 1.025-1.035.	gal.	.45	—	
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.33	—	
Pine tar oil, double ref., sp. gr. 0.965-0.990.	gal.	.65	—	
Pine tar, ref., thin, sp. gr. 1.06-1.10.	gal.	.85	—	
Turpentine, crude, sp. gr. 0.900-0.970.	gal.	.85	—	
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.	gal.	.30	—	
Pine wood croosote, ref.	gal.	.48	—	

Naval Stores

The following prices are f.o.b. New York, for carload lots.

Rosin B-D, bbl.	280 lb.	\$16.80	—	\$18.25
Rosin E-J.	280 lb.	18.50	—	20.75
Rosin K-N.	280 lb.	21.00	—	24.00
Rosin W. G-W.	280 lb.	24.50	—	28.00
Waxed rosin, bbl.	280 lb.	17.00	—	18.25
Spirits of turpentine.	gal.	1.73	—	1.75
Wood turpentine, steam dist.	gal.	1.68	—	
Wood turpentine, dest. dist.	gal.	1.50	—	
Pine tar pitch, bbl.	200 lb.	8.25	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	13.50	—	13.75
Retort tar, bbl.	280 lb.	14.25	—	14.75
Rosin oil, first run.	gal.	1.16	—	1.20
Rosin oil, second run.	gal.	.88	—	.93
Rosin oil, third run.	gal.	.95	—	1.07
Rosin oil, fourth run.	gal.	1.05	—	1.10

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	\$0.33	—	
70-72 deg., steel bbls. (85 lb.)	gal.	.314	—	
68-70 deg., steel bbls. (85 lb.)	gal.	.29	—	
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.231	—	

Crude Rubber

Para-Upriver fine.	lb.	\$0.34	—	
Upriver coarse.	lb.	.32	—	.32
Upriver caucho bbl.	lb.	.32	—	
Plantation—First latex crepe.	lb.	.49	—	.50
Ribbed smoked sheets.	lb.	.48	—	.49
Brown crepe, thin, clean.	lb.	.17	—	.17
Amber crepe No. 1.	lb.	.46	—	.47

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b. New York.				
Castor oil, No. 3, in bbls.	lb.	\$0.184	—	\$0.19
Castor oil, AA, in bbls.	lb.	.21	—	.22
China wood oil, in bbls.	lb.	.224	—	.23
Cocconut oil, Ceylon grade, in bbls.	lb.	.174	—	.184
Cocconut oil, Ceylon grade, in bbls.	lb.	.194	—	.20
Corn oil, crude, in bbls.	lb.	.16	—	.20
Cottonseed oil, crude (f.o.b. mill).	lb.	.16	—	.20
Cottonseed oil, summer yellow.	lb.	.234	—	.26
Cottonseed oil, winter yellow.	lb.	.214	—	.22
Linseed oil, raw in lots.	gal.	2.04	—	2.12
Linseed oil, raw, tank cars.	gal.	2.08	—	2.10
Linseed oil, boiled, car lots.	gal.	2.00	—	2.14
Oliver oil, commercial.	gal.	2.30	—	2.50
Palm, Lagos.	lb.	.17	—	.174
Palm, bright red.	lb.	.164	—	.174
Palm, Niger.	lb.	.16	—	.17
Peanut oil, crude, tank cars (f.o.b. mill).	lb.	.194	—	.22
Peanut oil, refined in bbls.	lb.	.28	—	.28
Rapeseed oil, refined in bbls.	gal.	1.50	—	1.60
Rapeseed oil, blown, in bbls.	gal.	1.57	—	1.70
Soya bean oil (Manchurian), in bbls., N. Y.	lb.	.17	—	.18
Soya bean oil, tank cars, f.o.b., Pacific coast.	lb.	.14	—	.15

FISH

Winter pressed Menhaden.	gal.	\$1.28	—	
Yellow bleached Menhaden.	gal.	1.30	—	\$1.31
White bleached Menhaden.	gal.	1.30	—	
Blown Menhaden.	gal.	1.34	—	1.36

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated.	ton	\$25.00	—	\$36.00
Barytes, off color.	ton	20.00	—	25.00
Blanc fixe, dry.	lb.	.034	—	.044
Blanc fixe, pulp.	ton	35.00	—	47.50

Shells, orange, superfine.	lb.	1.20	—	1.30
Shells, A. C. garnet.	lb.	1.30	—	...
Shells, bleached, better.	lb.	1.30	—	...
Shells, bleached, fresh ground.	lb.	1.20	—	...
Soapstone.	ton	15.00	—	25.00
Talc, domestic.	ton	16.00	—	60.00
Talc, imported.	ton	55.90	—	60.00

Refractories

Following prices are f.o.b. works:

Chrome brick.	net ton	80-90 at Chester, Penn.
Chrome cement.	net ton	45-50 at Chester, Penn.
Clay brick, lat quality fireclay.	net ton	45-50 at Clearfield, Penn.
Clay brick, 2nd quality.	net ton	30-35 at Clearfield, Penn.
Magnesite, dead burned.	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2 in.	net ton	80-90 at Chester, Penn.
Silica brick.	net ton	41-45 at Mt. Union, Penn.

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	\$200.00	—	\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon.	lb.	.30	—	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon.	lb.	.70	—	
Ferro-manganese, 70-80% Mn.	gross ton	105.00	—	115.00
Spiegelstein, 16-20% Mn.	gross ton	30.00	—	30.00
Ferro-molybdenum, per lb. of Mo.	lb.	2.50	—	3.00
Ferro-silicon, 50%.	gross ton	85.00	—	95.00
Ferro-silicon, 75%.	gross ton	150.00	—	175.00
Ferro-tungsten, 10-15% W.	gross ton	40.00	—	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	1.25	—	1.40
Ferro-uranium, 35-50%, of U.	lb.	7.00	—	
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	5.00	—	7.00

Ores and Semi-finished Products

Chrome ore, 35-40% Cr ₂ O ₃ .	unit	\$0.60	—	\$0.80
Chrome ore, 40% and over.	unit	.90	—	
Coke, foundry, f.o.b. ovens.	net ton	5.50	—	6.00
Coke, furnace, f.o.b. ovens.	net ton	4.00	—	5.00
Petroleum coke, refinery, Atlantic seaboard.	net ton	12.00	—	12.50
Fluorapatite, f.o.b. mines.	net ton	20.00	—	20.00
Manganese ore, 45% Mn and over.	unit	.50	—	.75
Manganese ore, chemical (MnO ₂).	gross ton	60.00	—	70.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ .	lb.	.75	—	.85
Tungsten, Scheelite, 60% WO ₃ and over, per unit of WO ₃ .	unit	9.00	—	15.00
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ .	unit	7.50	—	10.00
Uranium oxide, 90%.	lb.	6.00	—	
Vanadium pentoxide, 99%.	lb.	.60	—	
Pyrites, foreign, lump.	unit	.13	—	
Pyrites, foreign, fine.	unit	.13	—	.174
Pyrites, domestic, fine.	unit	.13	—	
Ilmenite, 52% TiO ₂ , f.o.b. N. Y.	net ton	40.00	—	
Rutile, 95% TiO ₂ , f.o.b. N. Y.	net ton	200.00	—	
Carnotite, minimum 2% U ₃ O ₈ , per lb. of U ₃ O ₈ .	lb.	2.75	—	3.00
Zircon, washed, N. Y. from foreign.	net ton	135.00	—	
Monazite, per unit of ThO ₂ , f.o.b. N. Y.	unit	42.00	—	

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags.	bbl.	\$2.30	—	
Lump lime, common, including container.	300 bbl.	2.63	—	
Common brick, at dock.	M.	15.00	—	
Yellow pine, 3x4 to 8x8, 20 ft. and under.	M.	48.00	—	
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis.	M.	55.00	—	
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis.	M.	55.00	—	
Roofings, tar felt (14 lb. per 100 sq. ft.).	ton	60.00	—	70.00
Roofings, tar pitch (in 400-lb. bbl.) carlots.	ton	21.00	—	
Roofings, asphalt felt carlots.	ton	34.00	—	
Roofings, asphalt felt carlots.	ton	63.00	—	
Roofings, slate-surfaced, per roll of 100 sq. ft. carlots.	ton	2.25	—	
Roofings, slate-finished shingles, 100 sq. ft. carlots.	gal.	6.08	—	
Linseed oil, 5 gal. cans.	gal.	2.30	—	
Red lead, dry, 100 lb. keg.	lb.	.13	—	
Red lead, in oil, 100 lb. keg.	lb.	.144	—	
Red lead, dry, 5 lb. cans.	lb.	.13	—	
Red lead, in oil, 5 lb. cans.	lb.	.164	—	
White lead, dry and in oil, 100 lb. keg.	lb.	.13	—	
White lead, dry and in oil, 25 and 50 lb. kegs.	lb.	.134	—	
White lead, dry and in oil, 5 lb. cans.	lb.	.15	—	

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.	100 lb.	\$2.45	—	
Angles, 3 to 6-in., 1-in. thick.	100 lb.	2.45	—	
Tees, 3-in. and larger.	100 lb.	2.45	—	
Plates.	100 lb.	2.66	—	
Rivets, structural, 1-in. and larger.	100 lb.	4.20	—	
Rivets, common for boilers, 1-in. and larger.	100 lb.	4.20	—	
Sheets, No. 28 galvanized.	100 lb.	4.35	—	
Sheets, No. 10 blue annealed.	100 lb.	3.55	—	
Sheets, No. 28 galvanized.	100 lb.	5.70	—	

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

Views on Potash: A Point of Time

IN THE pages devoted to "Readers' Views and Comments" we are glad to print a communication from FRIDERICK W. BROWN, commenting on the editorial entitled "Does American Potash Need a Fixed Price?" appearing on page 220 of the issue for Sept. 1. Mr. BROWN writes as the executive secretary of an association of nearly all the American producers, and his opinions bear special weight when it is known that during the war he, as a member of the Department of Agriculture's technical staff, investigated in detail the sources of fertilizer supply and the fields of American consumption. His statement is worthy of special emphasis: "The American producers quite agree with your claims that with correct technology they will be able to compete [with foreign importations] but," he adds, "they claim, with justice, in my opinion, that they must have a brief time to install equipment which shall be technically correct, and time to reduce somewhat the excessive capital investment which now stands against the plants."

Apparently, the only important point of difference between the responsible officers of the United States Potash Producers' Association and CHEMICAL & METALLURGICAL ENGINEERING is that of *time*. They say the industry needs "a limited and temporary protection" of "two years as an irreducible minimum." On the other hand, we have stated that "the American potash industry can stand on its own feet, and can now compete with foreign importations."

It has now been nearly a year since the Armistice was signed, since war ceased. During that time many American producers have been temporarily idle, owing to inability to sell their accumulated stocks, but these have practically all been disposed of within the past few months at a price ranging close to \$2.25 per unit. During that time about 8000 tons K_2O have been imported from French sources, and have been sold at from \$1.50 to \$1.70 per unit. Compared to the actual needs of the country—doubtless 300,000 tons K_2O —this amount of Alsatian potash is so small that its effect on the price of the meager American supply should have been small indeed. Actually, it did have a profound psychological effect, since the purchasers of potash affected to believe they would get an immense amount of cheap foreign potash immediately, and advertised this idea in order to get local potash at an unduly low price, judged by the relation of supplies to requirements.

Thus a year has passed without ruinous competition from abroad. An acute shortage of potash still exists, and famine prices should rule. As for the future, even the optimistic statement of Dr. GALE of the Geological Survey that there may be available during the next 12 months 50,000 tons of pure potash from Alsace and an equal quantity from Germany should not cause American producers to throw up their hands in despair. Germany and France are both so poor that it is inconceivable but that they will try to get as much for their exports as the market will pay. Their costs have largely increased, corresponding to the general inflation of prices the world over, and even with the maximum production from American sources, there will still be available less than two-thirds the amount which could economically be used in America. All of these facts point to a relatively high return for local potash for at least another year.

Here are the two years asked for by the best of the American plants. We are of the opinion, therefore, that potash men in the United States have been given and will still have months of breathing space in which to reorganize and stabilize their finances, and to perfect their processes. This period results from the operation of slow-moving world-wide economic conditions rather than unstable national restrictive legislation. A wise man grasps his opportunities, and makes the most of them.

The Sorry Plight of Our Educational Institutions

EMERGING from the war period and attempting to resume their pre-war activities, American colleges and universities find themselves seriously handicapped for funds with which to meet the increased cost of conducting their business. Most of them have fixed incomes, either from endowment or the State; and the problem of increasing their resources is made difficult by awaiting benefactions and bequests in the first instance, or tardy action by State legislatures in the second. In either event, expansion is retarded, salaries remain so unattractively low as to fail to hold good men on the faculties, and the authorities are confronted with the prospect of a stagnation worse than dissolution.

Harvard and the Massachusetts Institute of Technology have undertaken to raise additional endowment funds among their alumni and friends. There are other similar movements, and we welcome the opportunity to approve the general campaign for the decent support of our schools and educators. The latter are notoriously underpaid. They doubtless expect to

forego affluence and luxury, living simply and in contentment, but at the present time they are paying too high a price for their mental and spiritual advantages. The hod-carrier and the window-washer, to say nothing of that modern MDAS, the ship-riveter, so far outstrip the poor professor in wages as to gain for him more sympathy than usual. It is not difficult to prove quite logically that teachers would all have higher salaries if their pay were commensurate with the required ability to fill their positions and the responsibility devolving upon them and their labors. They deserve better of the public; but instead of striking they merely resign and get a more remunerative, if less attractive, job. One of the most important features of the Harvard and "Tech" plans for new endowment is an increase in faculty salaries to respectable proportions. For this, if nothing more, the movement is commendable.

Welfare Work or Manpower Engineering

HERE is a dictum on "Welfare or Manpower Engineering" which was lately published in the *National Efficiency Quarterly*:

"Exit welfare work; built upon benevolence, fostered by generosity and supervised by industrial missionaries. Enter manpower engineering; established on identity of interest and charged to operating costs."

It feels good to deliver an aphorism, and we've no doubt that the author of the two above sentences has enjoyed life in augmented measure since they were first uttered. But this "exit welfare work" and "enter manpower engineering" worries us a little. If we don't look out we are likely to run amuck on the subject of engineering, and to think that it means what it does not. Engineering has to do with the science of making and using engines and machines and with such designing of works as requires special knowledge of materials, machinery and the laws of mechanics. That is substantially the definition of the Standard Dictionary, and we think it a better one than a number of all-encompassing and braggadocio definitions that have lately been going the rounds.

Manpower is exercised by the man himself, and not by his boss. We must remember that. If the man who exchanges his power for wages is to exercise judgment in the functioning of this attribute, then he becomes the engineer of his manpower, and his boss becomes the engineer of his judgment—which is stretching the concept of engineering too far. If we use the word in this sense, then the mother becomes a family engineer when she sends for the doctor to visit her sick child. And the physician becomes a nutrition engineer when he prescribes lime water to be added to the child's milk. And if we are all to get aboard the engineers' band wagon, then the writer of these lines, who is a testy old party, will put in his claim for classification as a script engineer.

Nobody likes welfare work that is designed to make him over according to the judgment of somebody else. This may be the reason why boys are ever in collusion against the schoolmaster. He wants to improve their minds by so many lines of Virgil's *Æneid*, and they want to quicken their faculties on the baseball diamond. Everybody wants to be free to use his judgment, whether he has any or not. It is out of this de-

sire that all our songs of freedom are born. But we can't get away from welfare work. We may have to give it another name, because so many disagreeable and unpleasant persons have engaged in it, but no conscientious employer can dispense with it. Every decent man is engaged in welfare work among his neighbors when he tries to make the neighborhood agreeable and pleasant. This is equally true of the rich and of the poor. Welfare work is co-operative; it isn't patronage, although it must be benevolent.

We are obliged to maintain welfare work, and it should be built on benevolence. It is a mistake to think that a man must wear white whiskers and be rich and arrogant to be benevolent. Indeed he cannot be benevolent if he is arrogant. Benevolence indicates kindness of heart, and if employers are to forego the practice of benevolence in its true sense, a bolshevik rule is the best that they can expect or even deserve. And unless welfare work is fostered by generosity it will be too uncomfortable to endure. Good housing conditions in isolated manufacturing villages are part of welfare work, and if laborers' houses are built by a mean man the laborers' family life is spoiled. Generosity is essential.

If the "industrial missionaries" who are said to have supervised welfare work are efficiency engineers, we think the point well taken. They cannot solve the labor problem. If they are snobs of any description, the point is also well taken. But if they are wise and conscientious employment managers and district nurses and men and women who understand that the flowering of welfare work and benevolence and generosity is in co-operation, then we think that they are the only kind of persons who can supervise it.

Now let us consider the second sentence: "Enter manpower engineering." We do not believe there is any such thing. There might be slavepower engineering, but manpower engineering is impossible in a free country. Granted for the sake of argument, however, that it is possible, then it cannot be established upon identity of interest, because, if a man's judgment is not permitted to function he is playing a losing part despite high wages—unless he is a moron, in which case he should not receive high wages.

The idea of charging things to operating expenses is well established. Operating expenses are like the commercial traveler's expense account, and sometimes they carry a considerable burden, especially the burdens of error. We know of financially successful establishments surrounded by dirty, tumble-down tenements with bad Americans in the making in them due to lack of welfare work, rather than to low wages. In these instances the operating costs have been underladen—unless there were errors of judgment to boost them. But high operating expenses do not indicate good labor conditions any more than a high expense account indicates a good salesman. We do not think the second postulate in regard to the triumphal entry of manpower engineering established on identity of interest and charged to operating costs is illuminating. We're sorry to say that we can't see that it points toward greater enlightenment. It is not the key to the labor problem.

We wish the English language were held in higher esteem than it is, and that it were used with greater discrimination.

Does American Potash Need a Fixed Price?

To the Editor of Chemical & Metallurgical Engineering

SIR:—The editorial "Does American Potash Need a Fixed Price?" in your Sept. 1 number has come to my attention. Will you permit me to point out certain facts which I think the writer of the article has overlooked?

In the first place, the American potash producers were not responsible for the schedule of maximum prices included in the bill now before the Ways and Means Committee of Congress. The original bill as drawn by the Department of the Interior and introduced in the Senate during the preceding Congress did not contain any such provision. The maximum prices were inserted by the Senate Committee on Mines and Mining, and were included in the present bill only because of the insistence of members of that committee. The potash producers have always feared that the inclusion of this schedule of maximum prices would tend to prejudice their just and equitable demand for protection from German dumping, and when the Ways and Means Committee of the House, during the recent hearings on the bill, suggested that these prices had better be eliminated from the bill, the attorney for the United States Potash Producers' Association immediately approved the suggestion on behalf of the producers. (Page 222, Hearings before Committee on Ways and Means on H. R. 4870.)

The potash producers have repeatedly stated that all they need is a brief period of protection to make the readjustments incidental to changed conditions. This period they have placed at five years at the outside and two years as an irreducible minimum. The better and more up-to-date plants can probably do with two years. On the other hand, some of the smaller plants will doubtless be unable to reach a competing status in five years. But the point to be marked is that the industry asks only a limited and temporary protection, and the producers firmly believe that with such a brief period of safeguarding they can put their plants in a position to compete in the open market with any potash sources on earth.

The reduction of costs to be effected during this temporary period of protection fall under two heads: First, amortization, including obsolescence. Built under war conditions, practically all American potash plants now represent a very heavy construction cost. In addition, since quick production of large tonnage was urgently demanded by the situation of the country and by the insistence of Government officials, large sums were spent on machinery and equipment of an experimental nature but on a commercial-sized scale. In other words, there was no time for elaborate laboratory and semi-commercial tests. As a result, equipment representing large sums has been scrapped and stands on the books today as a dead loss. Quick amortization of part of this excessive construction cost and cost of obsolescent equipment is essential to put the companies on a sound operating basis, and is a just and necessary charge against the product. Figures for amortization in two years were included in the estimates submitted to Con-

gress at the express urging of the War Industries Board. Second, improvements in operating practice. During the war the one essential thing was to get out a tonnage of potash. Reduction of costs both by refinements in operating methods and by development of by-products was a secondary matter and in fact received very little attention. With the passing of the war conditions such reductions of cost became of course of the first importance and are receiving the most earnest thought from American producers.

Two considerations operate against the possibility of effecting such reductions over night. In the first place, it takes time to devise, secure, install and shake down new machinery and labor saving devices to smooth operating conditions. It takes time to determine the possible by-products in raw materials, devise methods of recovery and arrange for marketing such by-products. In the second place, without a reasonable assurance of permanence for the industry, such as would be given by the temporary protection asked for, the necessary credit cannot be secured to finance the new installations and improvements.

Your statement, therefore, that "the American industry can stand on its own feet and can now compete with foreign importations, barring dumping, trade war, rebates and such unfair practices," is not in accord with the facts. The present quotations for foreign potash range from \$1.50 to \$1.70 a unit. Our producers cannot now meet these prices, but will be able to meet them and possibly lower them in a few years' time if protected from unrestricted European importations during the brief readjustment period. The American producers quite agree with your claims that with correct technology they will be able to compete, but they claim, with justice, in my opinion, that they must have a brief time to install equipment which shall be technically correct, and time to reduce somewhat the excessive capital investment which now stands against the plants.

The preference of the potash producers for a licensing measure instead of a protective tariff is based primarily on the fact that with a license system the consumer will get his potash cheaper than under an adequate tariff. With a license system such part of the country's demand as cannot be supplied by American producers can come in from abroad at a lower price, thus giving the farmer the benefit of cheap foreign potash, while at the same time furnishing American producers with a definite market. With a tariff the price of all potash would be raised to the level of American costs of production, and the American producers fear that such a measure would not secure the final approval necessary to enact it into law. This is set forth on page 79 of the recent hearings on House Bill 4870 before the Ways and Means Committee.

I shall be glad if CHEMICAL & METALLURGICAL ENGINEERING will publish the foregoing statement so that your readers may have the viewpoint of the American potash producers.

FREDERICK W. BROWN,

Executive Secretary,

United States Potash Producers' Association,
Washington, D. C.

Willard Gibbs Medal Presented to Dr. William A. Noyes

The Chicago Section of the American Chemical Society presented the Willard Gibbs medal to Dr. William A. Noyes, professor of chemistry in the University of Illinois, at a banquet held in Chicago Sept. 26, 1919. Mr. L. V. Redman, chairman of the Chicago Section, explained the nature and origin of the medal, which is awarded annually by a jury of 12 to an outstanding figure in American chemistry. The award may go to either industrial chemists or those engaged in fundamental research.

Dr. William H. Nichols, president of the society, presented the medal after a short address in which he reviewed the work and character of the recipient. Dr. Noyes spoke informally on the subject of "Positive and Negative Valences," reviewing the development of the various theories and the apparent conflicts that still have to be reconciled before we understand thoroughly the constitution of elements and their compounds. The following brief statement of Dr. Noyes' work, written by Dr. Julius Sieglitz of the University of Chicago,

DR. WM. A. NOYES

is reproduced from the *Chemical Bulletin*, the lively and efficient organ of the Chicago Section.

Dr. William A. Noyes is a veteran leader in American chemistry as teacher, as investigator and as a force in the American Chemical Society, ever working for high ideals and progress. As a teacher, he is most widely known for his textbooks in Qualitative Analysis and Organic Chemistry and his more recent texts in General Chemistry. In all of these books he approaches his subjects with a directness and saneness of thought and method, combining theoretical development and practical material, which make his texts singularly clear and convincing. In his research work he has covered an unusually broad field of subjects: to have done expert work of the highest character in the determination of atomic weights—he received the

Nichols medal for his work on the atomic weight of chlorine—as well as extensive and important work in the more complex fields of organic chemistry represents a breadth of knowledge and power which it would be hard to duplicate in any other man, not only in this country, but throughout the world. In recent years, Dr. Noyes has taken active interest in the most important and most absorbing problem of the day, the electronic theories of valence and atomic structure, and has not only contributed ideas deserving of careful consideration, but has also carried out one of the most painstaking investigations looking toward the isolation of simple electromeric compounds, such as $N \cdots Cl^+$, and $N^+ \cdots Cl^-$. This breadth of chemical interest, combined with a character of sterling honesty and a mind singularly direct and judicious, found one of its most important and happy outlets in the service of Dr. Noyes as Editor of the *Journal of the American Chemical Society*. Through many years, with a unique devotion and self-sacrifice of time and strength, Dr. Noyes brought our major journal to its present high standing among the chemical journals of the world.

All honor is due this modest, productive leader in chemical thought and chemical service to our country.

Production and Exportation of Mercury in Spain

Mercury is produced in the Provinces of Ciudad Real, Granada, and Oviedo, but the most important mines are those of Ciudad Real, which are located at Almaden and cover a surface of 485,187 acres. They are owned and operated by the State.

The *Estadística Minera de España* contains some interesting statistics as to the cost of operation of the Almaden mines during the year 1917. In this year excavations were made at 300 sites, at which 2765 cu.m. were excavated at a total labor cost of \$97,333. The average daily wage paid was \$2.50. The average labor cost per cu.m. was \$35.20. The archwork, solid walls and masonry erected for the interior support of the mines cost, for materials and labor, including transportation, timbers used for bracing galleries and shafts, etc., a total of \$155,477. Shop expenses for work not set out by contract amounted to \$15,931; the various articles classed as accessories cost \$81,658, and labor not otherwise specified added \$44,493 to the expense.

For labor used in distillation during 1917 the expenditure was \$76,132, and for supplies \$82,148. Ten pairs of Bustamante subliming furnaces, two Cermak-Spirek, continuous-movement furnaces for fine materials, and three double-pan furnaces of the same system for coarse ores were employed. In the Bustamante furnaces 7550 tons of mineral were treated, from which were produced 984,486 lb. of mercury. In the Spirek system 688,795 lb. of mercury were produced from 5616 tons of ore.

The exports of mercury from Spain for the years 1908 to 1916, inclusive, were:

Year	Lb.	Year	Lb.
1908.....	2,353,629	1913.....	2,746,386
1909.....	3,009,959	1914.....	2,099,978
1910.....	2,466,935	1915.....	2,694,394
1911.....	3,293,392	1916.....	1,752,538
1912.....	2,769,085		

A comparison of the figures of output and export shows that practically the entire production is exported—chiefly to Great Britain.

Exposition of Chemical Industries, Chicago

WHILE the doors of the Chicago Coliseum and First Regiment Armory opened on the Fifth Exposition at 12 o'clock noon, Monday, Sept. 22, the formal program ushering in the event was held at 8:20 in the evening of the same day in the auditorium of the Coliseum building, with Mr. Charles F. Roth, Exposition manager, acting as chairman.

The addresses given by men of prominence and high standing in the industrial and chemical world sounded the keynotes on matters vitally interesting to those engaged in the chemical industries and to the general public. The industrial worker can find salvation from present trying conditions, and happiness for us all, in application to his labors and research for our needs. The science of chemistry has found production of additional wealth in by-products from many processes. We must depend on industrial patriotism, and by the use of sound economic principles deliver all from the chaos caused by inapplicable theories and the terminology of vari-defined phrases. The path of the present-day chemist in his progress through the research period is infinitely easier than of old.

Welcome by Dr. Redman

Dr. L. V. Redman, in greeting the visitors, said:

We welcome the Exposition to Chicago as the first to be held in the West, and while it cannot be hoped that it will be held here as frequently as in New York, we wish to persuade the exhibitors that the advantages afforded by this location are fully as great. The exhibits show the marvelous results of five years' intensive research. In chemical discovery mankind has advanced a full generation, bringing with this progress a corresponding rise in the prices of commodities, and these prices are here to stay. We may be something of Bolsheviks about our hours of work, but this is only the result of a relaxation after the concentrated effort during the war period, and in a few months such spirit will pass away. Due to this rapid development we now are witnessing perhaps the greatest chemical exposition we shall ever see.

The chemical industry will move its center to the Western field. In 1910 the automobile manufacturing centers were along the Atlantic coast, but now the Middle West holds the greatest output. Chemistry is doing the same thing. Two per cent of all the chemists in the United States have come to Chicago during the last year, and the total number of chemists in this city has increased 25 per cent in number during the same period. Production of meats, cereals, steel, coal tars, dyes, pharmaceuticals is carried on in this locality and the center of production will be here in a short time.

We should observe that the average salary of the chemist has increased from \$1200 or \$1500 per year to \$3000, and while general prices have also risen, the salary increases has been in much greater proportion.

The four qualifications for a good chemist are ability to labor, research, discover and organize. The most remarkable document of the twentieth century, forgetting the League of Nations, was the one drafted by the Federation of Labor and presented to Congress in which it was stated that *the one means by which the*

workmen can develop better conditions exists in research, and that Congress should do everything possible to encourage it.

The doctrine has arisen that men believe there is plenty of wealth available for all and that the trouble is not due to distribution but to production. The laborer realizes his hope is in research and is to be congratulated on this point of view. If all the money of all the millionaires were distributed it would keep the country running only two weeks. Therefore, if the laborer keeps the thought of research and production before him he will produce the greatest happiness the country has ever known.

Gov. Lowden's Letter

A letter from Frank O. Lowden, Governor of Illinois, dated Sept. 18 and addressed to Mr. Roth, was read, as follows:

"When I accepted your very much appreciated invitation to address the Fifth National Exposition of Chemical Industries, it was with the qualification that if I were in the State on Sept. 22 and if no unforeseen contingency should arise. It now happens that I have been summoned to appear before the Appropriations Committee of the House of Representatives at Washington to discuss budgetary reform. Perhaps you know that Illinois in 1917 provided the machinery for an executive budget and has since been operating under it very successfully. I therefore feel it my duty to respond to the invitation from Washington and give the Appropriations Committee the results of our experience. I think you will realize that this is one of the most important subjects before the country and that it is my first duty to help Congress in any way I can in this very important matter.

"I wish you would present my greetings to your associates and assure them that I am deeply disappointed because of my inability to welcome this most important body of men to our State. Our people learned during the war the overwhelming importance of chemistry in war. I trust that they may now learn that those connected with the chemical industries can be equally helpful in the beneficent work of reconstruction in times of peace."

Letter of Charles H. Herty

Charles H. Herty, in a letter addressed to Mr. Roth, dated Aug. 28, wrote:

"This morning President Wilson officially authorized me to act for American interests in dye questions abroad. This makes it necessary for me to sail next Wednesday, and I expect to be absent from six to eight weeks. In connection with this matter one of my chief regrets is that this unexpected duty will take me away at the time of the Exposition. I am sure you know how much this grieves me, as I have been present on every occasion heretofore at the opening of the doors, and I regret especially having to miss this particular time in Chicago.

"Will you please convey to Governor Lowden my sincere regret that I shall not have the pleasure of hearing his words of welcome? I know you will be able to find some one who can make more fitting reply than I might

have made. I am writing to the chairman of the Chicago Local Section expressing my regrets. Good luck to you, and best wishes for unlimited success to the Fifth Exposition."

Address by Charles F. Roth

Charles F. Roth spoke in part as follows:

"Some few years ago it became our duty to take inventory of our industries to learn our ability to meet the enemy in war. Some months ago it became our function to examine our businesses to their vital parts to know their ability to meet the changed views and demands of the world. Business will not go back to its old methods; the war has taught greater efficiency and its requirements to manufacture all over the world. We must examine into the fundamentals of our operations and, regardless of our present methods, consider the reactions in the processes involved, construct a program and then, comparing it with our present methods, make changes here and there where needed. We must look into the chemistry of our work and methods; its laws are immutable, but they may be made to operate through different channels. Those are the things we must weigh; are our present channels the most efficient?"

"Chemistry, today, is playing its most important part in industry and as time goes on will play an ever increasing part; the business that is not founded and administered upon an honest chemical basis, using the most modern and efficient chemical equipment and processes, will be a laggard and failure in the commercial race. American chemical engineering has shown during the past four years its ability to meet all emergencies and the competition of its enemies. There are many manufacturers who do not realize that their organizations and businesses are built upon some chemical truth, that the origin of their business is founded upon some familiar chemical reaction, which, in its many phases, did they know them, would open whole vistas and ranges of thought, new fields and endeavors to them.

CHEMISTRY'S PART IN INDUSTRY

"All the mechanical industries and the arts use or adopt the products of the chemical industries for their purposes. You will further realize upon a moment's reflection that the chemical industries are the wealth-producing industries, for by them the raw and worthless material is converted into a useful and valuable product, the mechanical industries enhance through manufacture by form that which has already been made valuable, the arts give the intrinsic value to some few of the product of the mechanical industries. Humanity adds the sentimental value. There you have the whole gamut of values as they are brought into being. At the fountain head of all this is chemistry. It is the basis of life and industry. Even agricultural pursuits might be counted as a chemical industry, for we soon see that unless the soil is replenished with the constituents removed by the growing plant it becomes unproductive.

"Did all business men sense the value of a chemical study of their processes and place them upon a scientific basis, the result would put our domestic industries in an unassailable position, incomparable with the rest of the world.

"Inquire of the leading firms in every industry for the reason of their leadership. They know that the application of the imperative laws of chemistry to their operation has brought it about. The greatness of Chicago's packing house lies more in the chemical utilization of the waste than the shipping of the prime product. The greatness of the gas house is not in the gas; but in the dyes and pharmaceuticals made from the tar it recovers."

Relation of the Chemist to the Manufacturer

John W. O'Leary, President of the National Metal Trades Association, spoke on "The Relation of the Chemist to the Manufacturer," as follows:

"It is always a pleasure to see and hear loyal Chicagoans, and I thank Dr. Redman for his boost, for his words are true and I believe Chicago will become a big steel center. I am happy that the privilege has been accorded me to participate in the proceedings of this meeting of the National Exposition of Chemical Industries. I had no part in selection of the subject, which permits me to say what I wish.

"I was impressed last week in the East with the fact that we are facing a very critical and serious situation in the United States. I have always tried when thinking in terms of the great war to dwell not so much on its cost in money, in health, sacrifice or supreme loss of life, but more on the gain to the world through the war. It would be unfortunate if we forget the debt we, as survivors of the awful struggle, owe to those who fought the good fight and won for us world liberty. None can do them too much honor, and we would be ingrates indeed if we failed in our daily life and expression to give thanks to God and them for the victory. It seems to me, however, that we would be showing small appreciation and little reverence if we now only devote ourselves to acknowledgment of our debt by erection of monuments, memorials to those who won the war. The cost was too great, the struggle too long, to be content with such expression. We should rather feel the duty ours to honor them by accepting as our task the rebuilding of the world resources destroyed, the conservation of the resources remaining and the preservation of the lessons taught by experience.

OPPORTUNITY FOR CHEMICAL LEADERSHIP

"To you men of the chemical industries comes the opportunity to lead in these tasks. The war brought to all of us a realization of your value in almost every branch of industry. One of the oldest of professions has come into its proper sphere of importance. For, during the war, whether the need was a greater destructive explosive, a more dangerous gas, a more brittle steel, or a more ductile, the science of chemistry was the agency to which we looked. Or if the demands of armies called for more of cloth, or wood, or paper, or leather, or silk, or anything which natural resource or productive capacity could not supply, the chemist was called on to create the substitute.

"And now that we are realizing the effect of interrupted production, and of wholesale destruction, when we are realizing the economic cost, and the difficulty of supplying even our current needs when we know that it is essential that we also restore the lack in these years of war before equilibrium can again exist, what an opportunity is yours to serve the world! The awak-

ening of industry in general to its need for your assistance was marked during the years immediately preceding the war. The twentieth century began with such an appreciation.

"I have been interested all of my life in the steel industry. I have heard my father speak so often of the shipment of steel rails to the United States from England during his early manhood, and of the excitement over the discovery of the bessemer process. I have watched with interest the later development of the open hearth, and the impetus which that development gave to the industry. But it was not until the chemical engineers developed the use of alloys in steel, and the wonderful magic effects of heat treatment, that the full possibilities of the steel industry became apparent. Today the chemistry of steel makes us feel that no matter what phenomenal results have been demonstrated recently, more phenomenal results will occur, and that there is no more important factor in the further development of the steel industry than chemistry.

THE UTILIZATION OF BY-PRODUCTS

"But it is not sufficient that you have improved materially the quality and uses of steel, you have been developing at the same time the by-products, which for so many years were wasted. In so doing, you are making us independent of Germany and her tar compounds and adding materially to the wealth of the United States. It is noticeable that while almost every commodity has increased in price since the armistice, steel has been reduced, and that in spite of higher costs, in actual production of the steel itself. This has been made possible largely through the utilization of the by-products. It is entirely within the realm of possibility that the by-products of steel manufacture may bring profits equal to those of producing steel. Whatever the gain, it will mean much to the future prosperity of the United States.

"Today, we are the only great producing nation in position to carry on normal industry through finance, natural resource and comparative immunity from destruction of life from the war. While we are not taking full advantage of our position, because of industrial strike, we will recover quicker than others. Eventually, however, we must meet competition which will demand the keenest efforts. The farther we advance in utilization of our by-products to carry the cost of manufacture, the better we will meet whatever the balance of the world offers in competition. What has been accomplished in the steel industry is indicative only of the importance of chemistry in almost every basic line. The extravagant, wasteful methods which we employed in the use of our forest resources is forcing attention now. Through the use of preservatives we must conserve what we have left; and it is your province to develop those preservatives.

"The importance of the growth of your industry in the basic chemical field of chemicals, drugs and dyes, is clearly shown in the comparison of our export figures for those articles in 1913 and 1917. Our imports from Germany in 1913 amounted to \$21,000,000. Our exports in 1913 to all countries were \$30,000,000, while in 1917, partly due to higher prices, but still representing large increase in volume, our exports amounted to \$188,000,000. Surely no other American industry can show such a ratio of increase. The war gave both impetus and protection permitting this vast expansion.

American initiative, courage, and legislative protection must be forthcoming to continue onward progress. And so I might continue, if time permitted, to enlarge upon the importance of the relationship of chemistry to industry. You know, better than I can tell, how vital your field is to industry. But what of the preservation of industry itself? It seems to me that our industrial progress has for the past year been backward rather than forward, and no gathering of business men at this time should fail to recognize the seriousness of our present trend, and seek for the cause and cure.

"During the war, and more particularly since the armistice, we have been passing through successive stages of higher wage demands, higher profit demands; less hours, less work; more leisure, more extravagance; less responsibility, less patriotism; of course, the result is bringing higher costs, and a progress toward disaster. Economic truths have been discarded for theories which sound well but won't work. We are confused by a plethora of general terms, undefined in our own minds or in the minds of those who utter them. Living wage, collective bargaining, pronteering, labor as a commodity, partnership of capital and labor, the right to organize, shop representation, combination, a new era, democracy in industry, socialization of industry, are some of the terms used each day in every publication; in every forum. No one attempts to define what is meant, because every one has his own interpretation, and they nearly all differ.

"The great mass of American workingmen just want to work—the great mass of American employers just want to produce. They both recognize that they are interdependent and have co-operative interests, and if permitted to carry on, other conditions will correct themselves. But they too are confused by what is after all nothing more or less than an insidious Socialistic propaganda. Not that all who are striving to express their understanding of the multitude of new thoughts are Socialists. Many are honest, well meaning folk who have assumed a paternal interest in industry but are in no way responsible for its continuance, nor have they any practical knowledge of its conduct. Others are selfishly interested in the propaganda because it furnishes them their daily bread. Others are employers who either through conscientious belief or pressure have adopted new plans of relationship and are anxious that they not conduct their experiment alone. And industry suffers! Five months of honest productive effort of American industry will supply all of our own needs, and permit of seven months' effort to replenishment of the world. Yet at our present rate of progress, we are unable to supply our own needs.

GERMANY'S PRODUCTIVE MAN POWER UNIMPAIRED

"Until recently, all Europe was pursuing similar tactics. Each nation's industry was striving to emulate the progress of Russia under Lenine, who has put into force all of the theories which we are talking about, as he understands them. I do not know whether his interpretation isn't likely to be as correct as any of ours. But today, at least two of the nations who have been passing through this after war orgy are recovering. Belgium is no longer striving to see how few hours she can work, but rather how many hours bodily strength and health will permit. Germany, under pre-war conditions a wonderful industrial nation, has lost heavily in man power. But before the war 3,500,000 of her

men were constantly removed from industry for military purposes, and millions more were engaged in supplying those 3,500,000. Today there is no such drain on her industrial man power and the release of this burden more than offsets her losses during the war. They have stopped talking about the eight, seven or six hour day, and are ready to devote ten, eleven and twelve hours a day to restoring her industrial position.

"Whether or not we are living in a new world, or a new era, the same sun shines, the same God rules. None of the formulas of chemical reaction have changed. We continue to progress in the discovery of new things, but they do not develop over night. Time and honest effort, not laws or theories, will make the discoveries available for service. Progress must be step by step, and each step will succeed only as the proper reagents are used. I remember from my days in chemistry that it required hydrogen and oxygen to produce one of the necessities of life; that it required two parts of the hydrogen and one of oxygen to accomplish it; either a different element or different proportion meant failure. If we substituted sulphur for the oxygen we made an awful stench. *As I see it, industrial relations operate similarly to chemical relations. To reach proper results we must rely upon employer and employee, and in their proper proportion. Too much power on the part of either will not make the compound desired.* The substitution of another element will make a stench, and the addition of another element will not produce the desired result.

IMPORTANCE OF LABOR CONFERENCE

"Two weeks from today the Labor Conference called by the President of the United States will assemble in Washington. Its importance to industry is emphasized by the request of the President to union labor to await results of the conference before inaugurating further strikes. The corollary is that if results of the conference do not follow the desires of the Federation, strikes will follow, and we must continue the disastrous experiences of the past year. It is important, therefore, to analyze from the President's speeches and trend his views on proper solution. He has expressed his belief that society sanctioned the eight-hour day; he has approved collective bargaining, though not clearly defined as to method; he has said that he would offer a new basis for wages; he has indicated that workmen should be partners in industry; he has advocated placing employees on the boards of directors; he has shown sympathetic approval of the organization of all workers. As I indicated earlier, much depends on the interpretation we give to terms or words. *Under any interpretation, a program based on immediate adoption by American industry of these principles would result in chaos.* Unrest is too keen for the launching of any definite plan of development of theories which, whether good or bad, must be gradual in their presentation; adopted only after experiment in a small way has proved their success, and debated and studied when men are calm and their judgment keen, rather than under hysterical and restless conditions.

INCREASED PRODUCTION THE ONE THING NEEDED

"I hope, therefore, that all men of industry who meet together, whether employer or employee, will consider the seriousness of our industrial future, calmly and without passion, and I hope that as a result of such

thought they will express to the President their hope that in this critical period of unrest no radical suggestions be inserted to further complicate conditions. Industry is in no position to absorb further departures from established practice than are now being tried. The general public cannot add to the burden being carried by them. Increased production is the only method which will make permanently possible improved standards of living or working conditions.

"Our greatest need today is for a reawakening of the patriotic impulses created during the war. Now, the slogan should be '*Industrial Patriotism.*' Today we need not so much discussion of rights of capital and labor as two opposing classes, but rather a campaign for industrial patriotism. The war awakened in us a spirit of enthusiasm for country and flag, dormant for many years. The reaction at its close is dissipating a great national asset. Selfishness is reasserting itself. Under the spell of national stress we all labored, not as classes, but as Americans all. The nation is in serious peril if we continue to drift industrially as we have since the armistice. Opportunity invites us, as American citizens, to prosper, and as American citizens, not as classes, we should accept, and fight together for commercial supremacy of the world.

How Long Does It Take to Develop a Laboratory Process Into a Dividend?

Herbert H. Dow, speaking on this subject, said:

"Almost everyone is interested in connecting up his profession with a dividend. LeBlanc, who was the founder of the first chemical process that attained any magnitude, spent about 15 years in building and attempting to perfect a chemical plant for the manufacture of soda ash. During this time the French Revolution impeded his work seriously, and the newness of his ideas made his problems more difficult to solve than those we now encounter in similar work. After spending all these years without attaining his goal, he became discouraged and died by his own hand. About 55 or 60 years later, Ernest Solvay had perfected a laboratory process for the manufacture of soda ash; after spending about 10 years in perfecting the process of manufacture on a large scale, it attained commercial success, and a few years later it became one of the most phenomenally successful processes ever devised. It is very difficult to obtain information in regard to the details of development of these processes that are only known to us through the various publications that have been made from time to time. For this reason I think you will be more interested in hearing of the development of processes that I know more about.

THE BROMINE PROCESS

"The bromine process of the Dow Chemical Co. was first conceived in the summer of 1888. A small commercial plant was built in 1889 at Canton, Ohio. This plant was a commercial failure for a number of reasons, among which were the lack of business experience and also the inadequate supply of raw materials. In the summer of 1890, another commercial plant was erected at Midland, Michigan, using electrolysis instead of chemicals for setting bromine free from its combinations in the brine, and unlike the method then generally employed, it used air instead of steam to blow out the bromine. This plant also was a commercial failure because of many things, among which were the inexperi-

ice of the management, and also the fact that the process was a little ahead of the times. I can best explain this last by an illustration:

"We wanted an electric generator having a capacity of 500 amp. at 15 volts. We wrote to all the manufacturers of generators, and most of them that thought a reply to our little concern was worth while stated that 15 volts was too high a voltage, that plating vats had already been tried, connected in series, and found to be a failure, and that 5 or 6 volts was the highest practical limit. True, 120 volts for lighting purposes was standard at that time, but the idea of making 30 or more electrolytic cells and connecting them in series looked like too radical a departure. The manufacturers also said that 500 amp. was too big a current to commute properly, that it would burn up the commutators in spite of the best design then known. We finally succeeded in buying the type of generator we required and installed the little plant in an old barn. Every part of this plant gave trouble. The generator in particular required constant attention to prevent the commutator and brushes from being burned up, and under the most favorable circumstances the cost of electricity for the commutator attention alone was a large item.

FIRST PLANT A FAILURE

"Finally, in spite of working 18 hours a day, more or less, the plant became a commercial failure, and the company was reorganized with two new partners to supply additional funds. After operating in this way for a few months it became apparent that it would again be a failure, and my first partner, who was a man of successful manufacturing experience, stated that the trouble was that we were trying to operate on too small a scale, with too little capital. We therefore attacked the problem from the financial end, and six or eight months later we began the erection of a relatively large plant. It called for a 50-kw. generator, and in the spring of 1892, I went to Cleveland to purchase this huge dynamo. The man in charge of the General Electric office after a considerable time asked me how large a 50-kw. generator was. Another firm offered to furnish it in three units, saying that it was impossible to run such large units continuously.

FIRST DIVIDEND PAID IN SIX YEARS

"We finally succeeded in buying the generator, and six years from the time we started commercial work we paid our first dividend. This illustrates how the interval of time between the successful laboratory process and the dividend was lengthened by the demands of the process being in advance of the electrical art at that time. More accurately stated, the electricians were too slow for the chemists. If the modern cell had been in existence at that time it would not have been a commercial success, because there were no suitable electric generators, but for the much higher priced bromine, with its higher electrochemical equivalent, the imperfections of the generators were not fatal to the electrolytic process.

"Analysis of the brine we were working on showed that it contained a larger per cent of magnesium chloride than other brines in this country, and we began to do research work with a view to extracting it profitably. About that time I learned that a number of carloads of iron sulphate had been sold for \$3 a ton. We found that by precipitating the magnesia from the brine

with lime and mixing it with ferrous sulphate and exposing it to the air it would slowly oxidize to ferric hydrate and magnesium sulphate. We decided that the best way to carry out this reaction was to spread the moist mixture of ferrous sulphate and magnesium hydrate on the floor of a long shed and cultivate it with a horse and farm cultivator once a day for several days until it was completely oxidized, and then remove it with a horse and scraper and add a new batch in a similar way. We went so far as to buy some leather boots for the horse but found that they had a very short life owing to the destructive action of the chemicals, and this, together with the difficulty of getting magnesia in the first place free from common salt, caused us to abandon this process.

TEN YEARS DEVELOPING MAGNESIUM CHLORIDE PROCESS

"From time to time other processes for making either magnesium sulphate or chloride were evolved, and tested out in the laboratory, and several of them were tested in a semi-manufacturing plant. Finally, in 1913, one of these semi-manufacturing plants made magnesium chloride in what appeared to be a very satisfactory way, and we therefore started the erection of a large plant. This was completed in August, 1914, a week or two after the war broke out in Europe, and when the Dow Chemical Co. began to sell magnesium chloride in carload lots within 30 days after war was declared, we began to be heralded far and wide in chemical circles as a very progressive firm that was able to get to manufacturing a heavy chemical on a commercial scale in 30 days. In this case, the first dividend was in reality about 10 years after the conception of our former process with its horse and cultivator.

"By this time we had a fairly large research and development organization, and practically every chemist in the plant was anxious to get his routine work out of the way so that he could work on some new process. In the fall of 1914 the price of carbolic acid had begun to soar and was attracting the attention of chemists everywhere. One of our organizations conceived the idea that monobrombenzol could be treated in an autoclave with caustic soda with the production of carbolic acid. It was already known that monochlorbenzol would make carbolic acid under these conditions, but the necessary pressure was 3000 lb., more or less, and we knew that the bromide would work at a much lower and more practical pressure. Actual tests showed that a high grade of phenol could be made without exceeding 300 lb. pressure. As this was within the commercial limits for fairly large pieces of apparatus, we immediately began the construction of a small plant.

"About the same time another group of our chemists thought they could make phenol by the process described in the literature. They tested it out in the laboratory and encountered no serious difficulties, and a semi-manufacturing plant was constructed and the various minor difficulties encountered were overcome. Then the price of bromine began to soar, and it became apparent that this process would entail too much investment in bromine to make it practical, so it was dropped and the old method adopted.

SUCCESS OF PHENOL PLANT

"The first plant built had an estimated capacity of one ton per day. It turned out its first product on the first day of November, 1915, and in this 30-day month

produced 59,000 lb., which was only 1000 lb. short of the capacity which had been estimated from the small-scale plant. This was the first time in our history that we had gone from a semi-manufacturing plant to a real manufacturing plant without experiencing troubles and months of delay. We attributed our success to a much larger and more mature development organization, and the further fact that after an organization once learns how to develop one chemical manufacturing process, it is much easier to develop another. In this case, the laboratory process and the dividend were less than one year apart, but we must take into consideration that the very abnormal war prices made a profit much more quickly obtainable.

"A high official of one of our largest electrical companies once stated to me that they had to figure on five years from the drafting room to the dividend on any product which was materially different from their normal line. The fact that the United States Government during the war could actually accomplish in six months or a year what an old experienced organization could not accomplish in a much greater length of time can be explained only on the ground that men of very unusual ability, and in much greater numbers than any commercial enterprise could command, were giving their services and the utmost energy which they possessed to the rapid development of these products so urgently needed by the allies. Aside from this fact, in the case of the Government, it was not necessary that costs be reduced to a point which would be essential for a dividend in a private enterprise.

"It is our experience that the method of evolving a successful process is somewhat as follows: The laboratory works out the process and compares it with the state of the art as shown in the literature, and if results would seem to justify the effort to make the process commercial, some further laboratory investigations are carried out, and then the laboratory force, without an exhaustive study of the subject, tests it out in a semi-manufacturing plant, made of commercial materials instead of glass and porcelain. Here a number of new problems will present themselves and will have to be worked out by the research men. After this plant is in successful operation, the draftsmen start their work for a large plant. In the meantime any uncertain points are still being investigated by the research organization, but an exhaustive study of the subject is not made in the research plant, as we have found by experience that there is no limit to the investigations that may be made at this stage, and many of the points which might be worked out would take months of valuable time which could better be employed at other work, even if we take some chances on a process not thoroughly developed. Finally, when the commercial plant begins to turn out a product, it is inevitable that certain details will have to again be worked upon by the development organization and the troubles remedied. Of course, in developing any new process, it is necessary to carry the laboratory work to a point where both the purity of the product and the yields are sufficiently satisfactory to make a commercial success; and a few hours spent with beakers and test tubes in the laboratory may be the means of saving days in the semi-manufacturing plant, and in a similar way, it is much cheaper to perfect a process in this semi-commercial plant than in the ultimate commercial plant.

SOME PERSONAL REMINISCENCES

"A new organization usually lacks some certain knowledge or experience—either business or technical—which constitutes a weak link in the chain. Again let me illustrate: Just after I was graduated, I made an analysis of a brine for a man in Canton, Ohio, for which I was to receive \$100, but after I had sent in that analysis I did not know how to get the \$100. If I had known as much about the customary methods of doing business as an ordinary clerk, I would have accompanied the analysis with a bill. When we got our first barrel of potassium bromide, I attempted to sell it. I first went to a school friend in Cleveland who was in the wholesale drug business. He did not use bulk bromides, but he took me to a man just starting in the brokerage business, to whom I stated that the price of potassium bromide was 35c a pound, but we were willing to sell it to him for 25c, and we were about to close a deal, when he said: 'By the way, these bromides are strictly U. S. P., are they?' I said: 'No, they are not strictly U. S. P., but they are equal to the best on the market.' He immediately replied that he could not use them, so I left him and went to an old reliable chemical house in another city.

"Here I explained that our goods were strictly U. S. P. in all respects but one and in that one were fully equal to any brand on the market. They said that they bought their goods from firms of high reputation, and that they did not dare buy from a little one-horse concern in Michigan, that it would affect their reputation if they did. However, they said they had a little business where purity was not so important and they might buy a little if the price was right, and they finally offered me 17c a pound, just one-half the market price. I accepted an order for two barrels and went back to Midland. We opened up the barrels of bromides to see if they looked exactly right. Here and there we found specks, and they were not in as good form as they should be, and we spent most of the next two days picking over the two barrels of potassium bromide crystals to remove every speck or imperfect crystal. We then shipped the two barrels and waited for a remittance. When a letter eventually arrived it stated that they had examined the bromides and found that they were not strictly U. S. P. and asked what concession in price we would be willing to make. That letter sent my heart down into my boots. We needed the money very much. We had closed the deal as we supposed at one-half the market price, what further concession should we now make? Fortunately for the future success of the organization, there happened to be a business man in our office who volunteered to answer the letter. In substance our reply was as follows: 'We are in receipt of your letter of recent date. If the goods are not satisfactory, please return them.'

"I was so scared that the goods would be returned that after signing this letter I was afraid to put it in the postoffice, but finally did, and the next letter from the firm contained a check in full settlement of the account. This letter was another step that shortened the time between the laboratory process and the dividend.

THE VALUE OF RECORDING INSTRUMENTS

"While we had expected to operate the plant night and day, our working capital got down to a point where this was practically impossible, so we cut the fo

down to the lowest limit and employed only a watchman at night. It was the duty of this watchman to keep up steam in the boiler and keep two deep well pumps operating so that we would have a full supply of brine to work on the following morning. Watchman's time detectors were not as common then as now, and recording steam gages were only just beginning to be used. We thought that these were unnecessary in our case, because we could tell by the amount of brine pumped during the night whether the watchman had kept the pumps running regularly, but for some unknown and mysterious reason the pumps kept breaking down at night.

"The man whose duty it is to repair these wells became very suspicious that Henry, the night watchman, was taking a nap occasionally and then in order to make up for lost time, was speeding the pumps up to a point that caused breakages. After these night breakages had occurred several times, I decided to go down to the plant along about the middle of the night and see if the watchman was asleep, but he had a little black and tan dog, and before I got within a hundred feet of the plant, the dog commenced barking furiously, and when I got to the boiler room I found Henry attending to business as usual.

"We were about to let Henry go and get another night watchman, but before doing so we decided to make sure of our suspicion by buying a recording steam gage, and secretly installed it in a closed box in the office. The first morning after it was set in operation we went down with a great deal of interest to see just what had happened during the night, but found that the steam line was very smooth and even and had been maintained at just what we desired. This caused us to believe that Henry did not take a nap every night but did so only occasionally. But when night after night the steam chart continued to report a smoother, even pressure for the night than it did for the day, we realized that our suspicions were unfounded and that Henry was really an unusually good night watchman. I think the advent of recording instruments marked the turning point in development from small-scale manufacture, where the proprietor had everything under his own eye, to large scale work where organization and automatic equipment is brought into fullest effect. If Mr. Solvay had had some recording pressure gages, it might have reduced materially the 10-yr. interval between the conception of his process and the dividend.

"In the case of the Parsons steam turbine, which was the first in the field, Mr. Charles A. Parsons made a statement before the English Parliament just before his British patent expired—which was 14 years from the date of application—that he had made no money, and asked for an extension or renewal of his patent. After investigation, an extension was granted.

"In all radical inventions, where public prejudice is a factor and a general campaign of education is necessary, it would appear probable that 10 years, more or less, would be consumed in making a new process profitable. While there are a great many statements in regard to the great length of time required to perfect the first indigo process, there are no data that tell when the earlier small plants began to be profitable. It is now more than ten years since the first indigo was

made in one of the laboratories of the Dow Chemical Co., but no serious effort was made to commercialize this process until after the war started, and about three years after it was decided to build a commercial plant the process became profitable. However, we had the advantage of much of the previous work done by others, which very much shortened the time required.

"Future development organizations will have the aid of better laboratory equipment, more perfect organization and greater experience, but to offset this, processes in future must be more highly developed in order to meet the prices of competitors who are continuously making their plants more efficient. We therefore leave it to yourselves to judge, but we trust that the few examples given may act as signposts along the way."

Motion Pictures

The program of motion pictures held each evening of the Exposition week in the Coliseum auditorium covered a large variety of chemical and industrial subjects and nothing could have been done by the managers to more fully insure the enjoyment of the visitors than this feature of the program. The profit derived by viewing the many reels exhibited was everywhere favorably commented upon.

Opportunities for Retired Technical Men in the Consular Service

Particularly gratifying results have followed the appointment to consular posts in chemical centers of men who had specialized in chemistry. This is one of the reasons why the consular bureau is looking more and more to the appointment of men with technical education to posts where their training will be of special value to the United States.

Due to the fact that the scale of pay in the consular service is not sufficiently high to be attractive to young men who must rely entirely upon their salaries, hope is being entertained that engineers and other technical men who have retired from active practice of their profession may be induced to take the examination. Service as an American consul abroad carries with it various desirable perquisites which would have compensatory value to many men who are not dependent entirely on their earnings, to say nothing of the very valuable service they would be able to render the industry with which they had been connected.

A consular examination will be held in the late fall or early winter and it is expected that it will be taken by a considerable number of retired technical men. Under the present statutory limitations, no consuls other than those of the first class are appointed except by competitive examination.

Calcium Superphosphate.—Calcium superphosphate made from phosphate which has been ground to pass an 80-mesh sieve, but not finely pulverized, is sifted or otherwise mechanically treated to separate the superphosphate particles, which are larger than the original phosphate particles, from the inert matter and calcium sulphate, which are not larger than the original phosphate particles. (British Patent 122,897—1918. E. A. GAILLARD, 3 rue de Batignolles, Paris, April 2, 1919.)

Observations Made at the Show

The best notes on the Exposition that we have seen are to be found in the advertising pages of our Exposition number. We say this without blushing. There are the illustrations and the facts. In what follows we shall give only random notes made in passing, gossip overheard, and memoranda recorded at various meetings at the Auditorium.

The Hough Nitrator shown last year by the Buffalo Foundry & Machine Co. was displayed in another unit and with slight modification. Aside from nitration it has found a variety of new achievements that are likely to bring it into general use. The main problem in nitration, of course, is the bringing together into contact, as nearly as possible, every particle of each of the substances; in other words, it is a problem of intimate mixing. This Hough apparatus is specially indicated in mixing oils of the type, say, of lubricating oils. To effect a proper blending of these mixtures as now accomplished by bubbling air through them often takes from 24 to 30 hr., while the product is often oxidized and thus darkened in color. This nitrator, it is claimed, completes the mixing in from 1 to 2 hr., does it better, effects a mixture of any desired proportions and in either large or small quantities. In an apparatus of 2500-gal. capacity the entire contents pass through the whole system twice every minute. The nitrator may also be used in washing a great variety of products at temperatures from those of cooling brines to those of superheated steam.

Another impressive exhibit of the Buffalo Foundry was a 2500-gal. caustic pot made of a special quality of cast iron to withstand the action of the alkali and heat.

A vacuum drum drier was in operation drying sulphite waste liquor and doing it successfully with remarkable speed. The operation is continuous. It is available for tanning extracts, soluble coffee, powdered milk, egg powder and a long list of pharmaceutical food and other chemicals. Still another exhibit was a vertical rapid circulation evaporator for concentrating foaming liquids and materials that demand a minimum exposure to heat.

While visiting at the booth of the Dow Chemical Co. it developed that this company is a large producer of pharmaceutical chemicals. And it is said that the largest use for bromine in the country is for medicines, the natural inference of course being bromo-seltzer. Sales are said to be increasing, which is a surprise, because we were under the impression that the requirement for bromo-seltzer would be retarded by prohibition. This, however, is not the case, from which we gather that near beer, grape juice and even loganberry juice may all be deadly and productive of drunkards' stomachs which were portrayed with such alluring art in red and purple in the days of our youth. The second largest demand for bromine comes from the photographic industry, which also consumes 30 per cent of the silver produced in the country.

Fused magnesium chloride ($MgCl_2 \cdot 6H_2O$) is made in very large quantities by the Dow establishment. This is used chiefly in the manufacture of magnesium oxy-chloride cement for interior work, which is of such interest that we plan to publish a separate paper on the subject later.

At the symposium on America's Case in Chemistry Dr. J. Merritt Matthews revised his figures as to the time when we shall have all the vat dyes we need that are made in America. At the Philadelphia meeting of the American Chemical Society Dr. Reese prophesied that we should have them within six months, which Dr. Matthews doubted. In the meantime he has visited a number of works and at the Exposition he predicted that we should have all we need by the end of the current year. That's a little more than three months.

In the exhibit of Roessler & Hasslacher considerable attention is paid to their peroxide products which are used for bleaching. Under the trade name of "Albone" they prepare a 25 per cent by volume solution of H_2O_2 , which is shipped in barrels as far as from Perth Amboy to Iowa without deterioration. It stands for months with practically no decomposition. We see a chance for research in the use of peroxides for bleaching in laundries and from the way in which the prices of shirts and collars are soaring we wish they would hurry. Chlorine as a bleaching agent is a grand thing for the shirt and collar makers, but the ultimate consumer is rarely able to appreciate the benefit. The same concern also shows peroxides of the alkaline earths and of other metals. Zinc peroxide is used in surgery and in toilet preparations.

An interesting item in the exhibit of the National Aniline & Chemical Co. is a specimen of moiré silk ribbon dyed with Dr. William Perkin's original mauve. His discovery of this dye and its tinctorial power marked the beginning of the coal-tar dye industry. Sir William presented it to ex-President W. J. Matheson, in 1906, shortly before his death.

Another unusual feature is a line of certified food colors made in a building erected and equipped for the purpose and in strict accord with the Government requirements. The main exhibit, of course, has to do with the company's large line of colors, including the following vat dyes: alizarine, indigo, carbanthrene olive (from carbazol) and alizarine sapphire, all of which are declared to be available in quantity. Within little more than one year's time this company has added 24 dyes to its list and made them available for commercial use. It is doubtful if any German establishment can show such a record. The company maintains a great research laboratory.

Two new products are shown by the Barrett Co. One is a synthetic resin called Cumar which looks important. It is made by the polymerization of two coal-tar oils which come over at about 172 deg. and 182 deg. C. respectively: cumarone and indene. It has great promise as a varnish gum and owing to its dielectric properties its use is indicated in molded insulation work. It is insoluble in water and alcohol, but readily soluble in turpentine, benzene and other commercial solvents. It serves also as a binder for various molded material. The second, phenanthrene, is available as a substitute for wax in paper and may be taken as the raw material in the synthesis of various morphine derivatives.

The Shawinigan Electro-Metals Co., Ltd., distributed a valuable booklet on the uses and qualities of magnesium. It includes details of foundry practice and a chapter on alloys.

When Dr. Augusti Rossi received the Perkin metal he announced that by the precipitation of a titanium solution by means of an organic acid he obtained the oxide in a state of very fine division. Ground with oil, it showed remarkable covering power as white paint. The exigencies of war prevented its manufacture on a commercial scale, but now, through a corporation called Titanium Pigment Co., Inc., it has been put upon the market under the name of "Titanox." This consists in a mixture of titanic oxide and barium sulphate in proportions of about one to four. Its covering power is decidedly greater than that of either white lead or zinc white. Tests show that it does not crack or check as readily as lead or zinc paints and that in the latter pigments the checking and cracking may be avoided by the use of 50 per cent or more titanox mixed with it. After long exposure titanox paints chalk to a moderate extent, but mixtures of lead or zinc oxide with titanox are more durable than any of the paints alone. An interesting showing is made.

Major Harrison E. Howe of the National Research Council said in talking of its plans at the general meeting in the Auditorium on Thursday, Sept. 25, that there are about 275,000 manufacturing concerns in the United States, of which less than one-fourth of one per cent have laboratories of any kind. Not over one-eighth of one per cent have laboratories worth mentioning and not over 50 in all have research laboratories.

He gave some details of the research organization for alloys which the Council is helping to organize. The plan is to have it more largely composed of manufacturers who need alloys than of those who make them. This is a wise move, and it is in the interest of economy, because it costs a lot more to introduce a new thing, whether it be an alloy or anything else, than it does to make it on specification. And it is also much more likely to bring improvements into use if users know they can be made and need them. It puts the shoe upon its proper foot. One hundred members will be enough to constitute the organization, and these are to contribute \$100 each per year for five years. While they will probably require their own central laboratory in time, it is proposed for the present to make use of existing commercial laboratories.

Initial steps are being taken for the formation of other similar associations. In all its work the Council seeks to avoid duplication of effort.

At a general meeting held at the Exposition Auditorium on Sept. 25 Mr. C. Price Green told of the field for industrial development along the lines of the Canadian National Railways. He gave some very interesting statistics, as for instance, that the United States, with 1/15 of the population of the world, uses one-half of the paper made upon it. Just as the writer's bosom was beginning to swell with pride over this he was reminded that all the Hearst papers were published in this country and that there are a considerable number of anarchist papers published not only in English but in foreign languages or that these latter constitute the only literature of any kind that reaches a good part of our foreign population. Then he cooled down. The Chicago Tribune uses the wood from 30 acres per day. All the Chicago newspapers use up 5000 spruce trees daily.

Canada produces 90 per cent of the world's nickel, a large proportion of its silver, 85 per cent of its asbestos. It contains the largest known gold mine, and a vast amount of copper. Deposits of sulphide ore have lately been discovered that are so rich that they are profitably hauled 60 miles for shipment by railway.

Graphite is under development by the Timmins people and he predicted that within a year's time there will be offered for sale from this source graphite that is equal if not superior to that imported from Ceylon and Madagascar.

There are marble deposits in Central Ontario that are the oldest on the continent and of unsurpassed beauty. The bodies are of immense magnitude and run for hundreds of feet in depth without a flaw. As the strata lie in a vertical position, the various varieties can be obtained with great economy. Water power is available for the operation, while the product may be run down to the railway by a gravity road.

Only lately manufacturers have begun to realize what potent factors chemists and engineers are. There is great need of technically trained men in that country.

In an address made by Dr. Arturo Liebes of *El Mundo* (a Havana newspaper) he displayed motion pictures of Cuba and her industrial life, he made an earnest appeal along lines that we have touched upon editorially. He protested against the type of representatives sent by American manufacturers to represent them in that country. He said that of 250 such men that he had met, nearly all were outspoken critics of Cuba and Cubans. Many of them made fun of their customers. They had no sympathetic viewpoint with the people. Whatever was done differently from the way current in the United States was wrong, according to these gentlemen. He earnestly hoped that a greater effort would be made to select the right type—which means a more cultured, sympathetic and affable type of export salesman for Cuba.

A clever exhibit made by the Semet-Solvay Co. was a miniature dairy farm covering about 3 sq.yd. Beside each building or field was a label indicating the Semet-Solvay products that are useful. The dwelling house, for example, could use domestic coke, while for the roads calcium chloride was needed to lay the dust. Beside the garage it was recorded that benzene was available for automobile fuel. The chicken house required coaltar disinfectants and germicides. In the creamery calcium chloride is needed for refrigeration, salt for the stock and for the creamery, while soda is required for cleaning. In the field the use of potash and ammonium fertilizers was indicated.

Another Solvay exhibit was a model in pyrex glass of a cotton-boiling kier designed by Mr. Scott for use in bleacheries to overcome a difficulty from which they suffered. A number of these kiers have been installed and are in successful operation. Their merit consists in the treatment of cotton with caustic in the absence of air, whereby the formation of hydro-cellulose is prevented. After the caustic is drawn off and the wax thus removed the cotton is washed with water and finally bleached in the kier, thus providing for a minimum of handling.

Chicago Meeting Mining and Metallurgical Engineers

Engineers of the Chicago Section entertained the 120th meeting of the American Institute of Mining and Metallurgical Engineers during the week of Sept. 22-26. It was a remarkable meeting in many ways, breaking all records in point of attendance, and in the number of technical papers presented. On Thursday, for instance, between the hours of 10 and 6, about 53 contributions on modern pyrometry and its industrial applications were presented to a largely attended joint meeting of the Institute and the Electrochemical Society. On other days as many as three simultaneous sessions were being held, while the many attractive trips of inspection, the Chemical Exposition, and the meetings held by five other engineering societies made it a difficult matter for the individual to be at the right place at the right time. Unfortunately for the local committee, as well as the visiting metallurgists, the steel strike badly disarranged the excursions planned, since under the circumstances it was impossible to visit any of the extensive steel works in the Chicago district. The usual banquet was held, which was addressed by President WINCHELL, and Messrs. PEABODY, ROBINSON and SCHWAB, where the underlying note was one that the engineer would be of enormous economic value in the next few years by promoting the necessary spirit of confidence between worker and employer so necessary for our industrial renaissance. Captain COUBLVT, of the French Navy, also spoke, recounting briefly the relation between the present mineral and metallurgical resources of France and their expected needs, together with an outline of the methods by which they expected to bridge the gap.

A very interesting group of about 20 papers on non-ferrous metallography and metallurgy were presented by title only, since they are to be the subject matter of a meeting of the Institute of Metals Division to be held the following week in Philadelphia, held jointly with the American Foundryman's Association, as is customary. These papers will be noted in detail in connection with a later report of this meeting. Pyrometric subjects will not be considered at this time, being reserved for special treatment at length in subsequent issues of CHEMICAL & METALLURGICAL ENGINEERING. A very important series of papers by FULTON, KELLER, MACKEY, HANSON and HULST on non-ferrous metallurgy must also, for lack of space, be deferred for later notice at length.

Monday, Sept. 23

Session on Milling

A paper in defence of the Chilean mill was presented by LUTHER W. LENNOX, assistant superintendent of the Portland mill, Victor, Colo. He pointed out that this type of grinder has fallen into disrepute of late years, and that in two published tests where they were operated on the same kind of feed alongside ball or tube mill the results were unfavorable to Chileans. However, the feed in these cases was exclusively fine; in other words, the mill was used as a re-grinder, while tests at the Portland mill have demonstrated that a certain amount

of relatively coarse material is necessary, upon which the millers may ride, and which easily act as auxiliary grinding units. Under this condition, with feed which may contain slabs 1 in. thick and 3 in. square, the millers and die are 2 in. apart at their edges and contain 5 in. of mixed sizes closely packed at the middle. With a feed exclusively finer—say, minus $\frac{1}{2}$ in.—the millers plow their way through the ore instead of rolling over it, and a much thinner bed of material is retained in the grinding zone. Results of a large number of tests are included to support the ideas of the author, while the records show that the mill will reduce the hard, refractory Cripple Creek ores from minus $2\frac{1}{2}$ in. as follows:

	Tonnage 24-Hr.	Size Product	Tons Hp-Day
Open circuit:			
With 6-mesh screens.....	275 to 300	28. 5% — 200 mesh	2.5
With 18-mesh screens.....	240	32% — 200 mesh	2.2
With 30-mesh screens.....	175	35% — 200 mesh	1.75
Closed circuit:			
With 6-mesh screens.....	200	42% — 200 mesh	1.86
With 18-mesh screens.....	185	47% — 200 mesh	1.72
With 30-mesh screens.....	130	52% — 200 mesh	1.31

The mills described consist of a battery of six 6-ft. Wellman-Seaver-Morgan Akron Chilean mills, each driven by a 100-hp. motor at 37 r.p.m. Power input is maintained at 110 hp. as near as possible, of which 10.7 represents friction in mill, motor and transmission. In the paper may be found detailed information as to relation of grinding efficiency as it varies with tonnage, dilution of pulp, speed of mill, position of miller, and screen analysis of feed, together with figures of steel and screen consumption.

Mr. C. H. BENEDICT, of the Calumet & Hecla Mining Co., observed that they had displaced a 48-unit Chilean installation by ball mills because their service was to grind $\frac{3}{16}$ -in. material to very fine sizes. For this work the ball mill is evidently superior, reducing the time lost for repairs from 3 per cent. to less than 1 per cent., while a uniform sized discharge is impossible from a Chilean, owing to progressive screen wear.

Mr. R. B. T. KILLANI of the Hardinge Conical Mill Co., pointed out that since the Miami tests referred to by Mr. Lennox were run, considerable advance in ball-mill practice had been registered. Using figures from Mr. Lennox's paper presented at the Colorado meeting on the relative "grindability" of various ores, which have been independently verified, Mr. Killani calculated figures which indicated the probable superiority of the ball mill on equivalent work, figured to mesh-tons per horsepower.

GRAPHIC METALLURGICAL CONTROL

H. M. MERRY, metallurgical statistician for the Chino Copper Co., Hurley, N. M., presented a short paper on "Graphic Metallurgical Control," in which he pointed out that the customary method of having several zero points on the same ordinate is likely to produce confusion in interpretation and to militate against its full usefulness. He shows that a logarithmic division of ordinates is more to be preferred, in that the low numerical values, such as "copper in tailing," are properly magnified to their true importance, as compared,

for instance, to the figures for "copper in concentrate." An even better ruling is the plain millimeter cross-section rolls wherein the notations roughly follow the mean logarithmic spacings for the region in question, but in this portion the plotting is on an arithmetical scale. The author also describes an ingenious wall cabinet for filing old charts in such a way that they are protected, yet instantly and easily accessible for comparison or study.

CRUSHING PRACTICE AT AJO, ARIZONA

Additional information regarding the crushing practice at Ajo, Ariz., was given in a short note by W. L. DUMOULIN, assistant general superintendent. It was found that when a carload (35 tons) of ore from the shovel pit was dumped into the coarse crusher (No. 24, style K, Gates) set to 9 in. it would pass material so rapidly that the four No. 8 crushers set just below receiving the discharge would be flooded. Concaves and mantles were therefore replaced, so that the larger crusher now breaks to 6 in. and the lower set to 3 in., instead of 4 in. as formerly. This distributes the work more evenly in the coarse crushing plant and takes much work from the secondary Symons disk crushers. A new unit has been installed in the latter department, making 5 in all, with a total capacity of 500 tons per hr., each consisting of one crusher, with a grinding surface 4 in. wide, reducing the ore from 3 in. to $\frac{3}{4}$ in., followed by two with surfaces 6 in. wide, delivering $\frac{1}{2}$ -in. material (only 18.3 per cent. through 20 mesh!). Repairs on the Symons machines have been reduced by strengthening various details and eliminating more of the tramp iron. Manganese steel used per ton of ore crushed is 0.0113 lb. in the Gates and 0.059 lb. in the Symons.

Tuesday, Sept. 23 Session on Iron and Steel

(Jointly with American Electrochemical Society.)

RAYMOND M. HOWE, of the Mellon Institute, presented a paper on "Blast-Furnace Refractories," in which he collects the results of a questionnaire sent to nine of the leading American furnace plants. Seven of the firms reported satisfaction with both furnace and stove brick, while the failures noted were due to obscure causes which would require detailed study to determine. Thus the refractory industry feels that it has probably met the more and more exacting demands of modern metallurgy with considerable success. The author points out the fact that fire-brick manufacture comprises seven distinct steps, each of which may be adjusted so as to influence quite definitely the quality of the finished product; makers are now giving close attention to all these matters, so that their product will suit the intended purpose as to melting point, density, strength, toughness and uniformity. On the other hand, it is obvious that the purchaser has much to gain in studying and specifying his exact requirements and then insisting that a correct mortar is used and the furnace is built exactly according to the engineer's drawings. When the useful life of the lining is passed, the furnace should again be carefully studied before dismantling starts. Only in this way can progress be effected. Disintegration of blast-furnace linings has been variously ascribed to the effect of carbon, deposited at 300 to 400 deg. C., to removal of iron by gases, and to deposition of alkali. The author points out that if the first

two causes are effective, linings could be made more durable by using an iron-free brick or by keeping them constantly above 400 deg., either of which is obviously impossible. On the other hand, there may be great savings made by developing a top-lining with a hard, impervious, refractory glaze.

EFFERVESCING STEEL

Two papers on the effect of gas in steel attracted much attention. The first, a clear exposition of the causes and results of "Effervescing Steel," was given by HENRY D. HIBBARD. He notes that the pyrotechnic display of burning steel particles splashed up from the ingot top during and after pouring is due to the evolution of a myriad of gas bubbles, the gas being rendered less and less soluble with decreasing temperature of the liquid. Three zones of blow-holes are caused by such gases entrapped in the mushy steel: First, holes near the surface due to hydrogen. These are relatively rare, because ordinarily but little hydrogen is present and its bubbles are largely washed away by the evolution of the enormous quantities of CO, which is responsible for the deeper-seated holes. Finally, at or near the axis are sometimes found cavities due to residual nitrogen or NH₃. Effervescing steels include most soft steels with less than 0.40 per cent. C, and when properly made (according to the principles laid down in the paper), the ingot will have a flat top with but few holes near the surface due to hydrogen. Even these, if covered by a thick skin of sound metal, so that they are unoxidized, will be welded shut during rolling. The deeper-seated holes are always bright and constitute no defect; in fact, they should be just sufficient in volume to produce a flat-topped ingot, in order that the minimum percentage of billet ends will be cropped.

DETERMINING GASES IN STEEL

The second paper on this subject was by J. R. CAIN, of the Bureau of Standards, who outlined the work which is under way toward developing a correct method of determining gases in steel. In a brief review of the previous work he noted that the simplest method in use, i.e., of drilling the metal under mercury and collecting the gases liberated, gives reliable qualitative results and indicates that a part of the total gas content is held imprisoned between crystals. Heating steels in vacuo is difficult and show that various amounts of gas are evolved at various temperatures, indicating, in fact, that fusing the samples will be necessary before quantitative results may be expected. Work along these different lines has disclosed considerable gaseous segregation; that rolling decreases the gas content; that the gases evolved are mainly H₂, CO and N₂; that the solubility increases with temperature and as the square root of the pressure. Detailed investigations have already shown that the Ledebur method of determining oxygen is inaccurate and valueless as an indicator of the physical characteristics of the steel itself, except in the rare case of very pure ingot iron, and that the gas evolved by Goutal's method is generated by carbides in the metal. The Allen method of determining N₂ is more promising, and many improvements in its technique are being made. Possibly it can be developed into the precise quantitative operation which is first needed before serious work can be started to determine the actual mechanism of the degasifying reagents (Mn, Al, Si); the effect of manipulation on gas content, and, finally,

how gas content affects the physical properties of the manufactured articles.

In the discussion of this paper, Mr. CUSHMAN pointed out that there were probably three separate methods of gas imprisonment; first, atmospheric air in cavities; second, gas in solid solution, and, third, combined in chemical compounds. J. S. UNGER pointed out that it is difficult to see how oxygen—which has been reported as being evolved from hot metal—can be present in quantity with such a large excess of iron or carbon. As a matter of fact, it is quite doubtful whether all gas in iron alloys is detrimental: witness the work which has been done on oxygenated cast iron and the growing use of gaseous cementation agents. Mr. YENSEN thought that other methods than melting in vacuo were necessary in order to get all gas from metal, since he has made many ingots held molten in vacuo for hours which are full of blow-holes.

THE EFFECT OF TIME ON PHYSICAL PROPERTIES OF MEDIUM-CARBON STEEL

"The Effect of Time on Physical Properties of Medium-Carbon Steel" was described in a paper by G. A. REINHARDT, metallurgist, and H. L. CUTLER, assistant of the Youngstown Sheet & Tube Co. In their effort to produce forging steel of about 0.50 carbon and high elongation it was found that test bars which had rested over night gave much better ductility than those tested immediately after machining. Pursuing this matter further, the authors found that improvement by rest was apparently confined to bars cut from ingots, or pieces on which but moderate amount of work had been expended; that rest at 120 deg. C. accelerated the beneficial effect, and that the speed of machining on the test bar seemed to be an immaterial factor.

An animated discussion followed this paper. Many members had used the expedient of aging to get test bars past the specifications, but conflicting opinions were expressed as to whether the forging also improved correspondingly. The interesting ethical point was also raised as to whether it was correct to give a test bar a low temperature anneal—for that is what ageing or accelerated aging really amounts to—in order that it may attain a certain physical specification.

AIRCRAFT STEELS

In a paper titled "Aircraft Steels," ALBERT SAUVEUR, of Harvard University, points out the confusion during the war which existed because of a multiplicity of aircraft boards, each working independently and constantly issuing revised specifications. No less than 175 different steel specifications had been more or less officially promulgated, when the Inter-Allied Committee on Aviation delegated some of its members to prepare some specifications truly international in character which could be issued to clear the chaos. Dr. Sauveur's paper is largely a reprint of this sub-committee's report, giving condensed specifications for chemical composition, recommended heat treatment and desired physical properties of eleven types of steel, some one of which would appear to be suitable for any particular part of an airplane where steel is desired. Fifteen other steels are included in a second category, in order to satisfy all members of the committee and to cover localized conditions of manufacture.

RIFLE-BARREL STEEL

Rifle-barrel steel was discussed in two papers by Major A. E. BELLIS and G. F. BUTTERWORTH, JR., of the Springfield Arsenal. These barrels are made of 0.55 C, 1.15 Mn steel in one of four ways: (a) by upsetting blanks, then quenching at 816 deg. C. ($Ac = 752$) and drawing for 2 hr. at 648; (b) by quenching billets from 816 and rolling at 677, (c) by rolling at or above Ac ; and (d) by rolling at 650 to 675. Method c gives structure apparently sorbitic at 100 dia., but resolvable into rounded particles of free ferrite in sorbitic ground mass. Method d gives typical banded grains, the original structure not being obliterated, merely distorted. Methods a and b give similar structure of homogeneous sorbite, substantially the same for all drawing temperatures, although the degree of heat can be determined microscopically by the tint after standard etching. In manufacture the occasional seamy pieces are almost always exposed, so that few failures result when proof-firing at 40 per cent. excess pressure. Erosion after continued firing is shown by tests to be resisted best by the true sorbitic structure, any network of free ferrite offering easily eroded channels for the scouring action of hot gases and metal.

Evening Session

A description, illustrated by lantern slides and moving pictures, of the huge 240-in. plate mill at Coatesville, Pa., was given by C. L. HUSTON. The speaker prefaced his remarks by a brief account of the development of boiler-plate manufacture and the rivalry which lately has existed between mills as to which could produce the largest plates for special purposes. This particular mill is so much larger than its predecessor that it will doubtless be unique for many years. Its construction, of course, involved the perfection of several radically new details in the stands, tables, manipulators and shears, all of which were clearly described.

FUTURE TREND OF MILL PRACTICE

ROBERT W. HUNT read his paper, suggesting the future trend of mill practice to attain a better grade of rails. Some seven years ago he instituted a special inspection, which has since been widely adopted with gratifying results. It consists of placing inspectors in all departments of the steel works at all times, charged with the duty of recording the history of each heat of rail steel. A copy of this is furnished the steel company, as well as the purchaser, so that in the life of any rail should a defect occur, not only a detailed record of its manufacture is available, but personal responsibility may be correctly fixed. Mr. Hunt has also recently recommended a nick-and-break test for each ingot, a practice which is now universally used on Canadian railroads. This merely consists in breaking a piece from the top end of the first rail rolled; if satisfactory, the whole ingot is accepted; otherwise, the bottom end of the first rail is broken, and so on until a fracture free from defect is found. Hot straightening of rails is another step in advance which is perfectly feasible, and which will when generally adopted materially cut the expense in this department, as well as result in improved and safer rails, with a much smoother roadbed. Use of liquid additions will enable more uniform chemical composition from basic open-hearth heats, while a

higher average carbon content could be secured if a certain percentage of marked rails with a small excess in carbon would be accepted by the railroads. Furthermore, there really seems no valid reason why all the railroads should not adopt the same chemical specification for their heavy standard rails, which, as a matter of fact, are about the same weight. Hot-top ingots seem not so far distant as a general requirement; milling both ends square, to precise length, is another matter of great importance. Hot milling about $\frac{1}{4}$ in. of metal from the outer part of the blooms from which the heads and flanges of the rails are formed has been instituted by one mill, and the process is working to their satisfaction. Perhaps some such expedient will be needed to reduce the growing number of failures due to longitudinal seams and their accompanying crescent-shaped flange breakages, a tendency unchecked by the use of thick flanges.

Wednesday Morning, Sept. 24 Session on Iron and Steel

Impact strength was the subject of a lively discussion precipitated by F. C. LANGENBERG's paper, where he described the results of Charpy tests on some forgings which failed in service and which, upon investigation, revealed low transverse ductility. The author considers that the test is of great value in testing ordnance material, basing his opinion on several years' use at the Watertown Arsenal in both routine and experimental testing. While admitting that notched-bar results are not yet directly correlated to more common physical tests, experience shows that low Charpy resistance or transverse tests indicates brittleness under suddenly applied stresses, a characteristic of the metal not revealed by static tensile properties on longitudinal specimens, even though low ductility transversely could be shown if bars were pulley in that direction. A. C. PICKENS gave a brief description of the machine in use at the Naval Gun Factory, which is a vertical drop machine, with graphic recorder drawing a curve of elongation vs. time. Velocity of stretch is given by the tangent to this curve at any instant; acceleration from time to time can then be easily figured, and with the weight of lower head known, a value for stress in pounds per square inch can be figured. This unit for expressing results corresponds to common practice in other tests, and will be an important factor in popularizing the method, especially since an integrating instrument has been designed for interpreting the graphs. On the other hand, Mr. NELSON said he had been experimenting with the Izod test for many months with the most erratic results. For instance, a sound carbon bar from stock, when split into sixteenths, would give tests ranging from 15 to 100 ft.-lb. in random sections within $\frac{1}{4}$ in. of each other. Alloy steels, on the other hand, are either consistently good or bad; that is to say, if a certain bar is good "notch-test steel," one cannot get low Izod numbers by even the most careless testing, while a poor "notch-test steel" can have its resistance increased from Izod 4 to 10 up to Izod 40 or 50.

COOLING PROPERTIES OF TECHNICAL QUENCHING LIQUIDS

N. B. PILLING and T. D. LYNCH of the Research Laboratory, Westinghouse Electric & Manufacturing Co., presented a very valuable paper comparing quan-

titatively the "Cooling Properties of Technical Quenching Liquids." Using experimental methods developed by Benedicks, the cooling curves of a small cylinder of nickel in liquids at various temperatures were studied, and the derived data summarized in diagrammatic manner. In general, there are three different stages in the quench: (A) a layer of vapor is formed between hot metal and cool liquid through which the heat transfer is slow; (B) the vapor jacket is condensed, and cool liquid comes in physical contact with hot metal when heat transfer is quite rapid, each bubble of vapor as formed being swept away by convection currents; and (C) as the metal cools off, ebullition ceases in the liquid and heat is transferred slowly at temperatures below the boiling point. It is thus seen how the physical properties of steels are quite materially affected by the varying quenching rates common in practice. Quenching oils in general are quite stable; i.e., the curves for a given oil are nearly parallel at all reasonable temperatures, with speed and duration of various stages almost identical. Concentrated sulphuric acid also is stable (in the above sense) and gives high quenching values because Stage A (vapor sheath) is entirely absent. Brine is second only to acid in speed of quenching up to about 40 deg. C.; above that temperature Stage A appears and becomes of increasing importance. Tap water, on the other hand, is very unstable, always producing a considerable period of slow cooling before Stage B sets in, which period lengthens rapidly as the initial temperature of the water approaches its boiling point. A concentrated soap solution at all temperatures quenches slowly because the vapor sheath persists down to metal temperatures approximating 400 deg.

HEAT TREATMENT OF CAST STEEL

An interesting account of the development of a double heat treatment for steel castings was presented by Messrs HALL, NISSEN and TAYLOR, of the Taylor-Wharton Iron & Steel Co. These men demonstrated to their own satisfaction that an anneal of from 2 to 4 hr. at 900 deg. C. was necessary to diffuse the original ferrite in low-carbon cast steel. This soaking must then be followed by relatively quick cooling to prevent the carbon re-segregating at the original grain-boundaries; air cooling was later replaced by oil or water quenching. A second anneal is necessary to remove hardening strains—it must be done below A₁ in order to retain the acquired carbon distribution. One peculiar result of their work was that it was shown that it is necessary to reheat to a lower point after quenching than after air cooling in order to prevent re-segregation of ferrite masses. Experimentation with electric steel of extremely low S and P content showed that practically the same heat treatment is necessary to eliminate ghosts entirely; the authors therefore conclude that good physical properties may be had more cheaply by heat treatment than by insisting on stringent chemical specifications. During the war, good results were had from a 0.25 C, 1.25 Mn steel perfected several years previously for dredge buckets. Intricate gun-carriage castings of this composition were made of basic electric steel, given the double treatment of quenching and annealing without the least trouble from cracking or difficulty in attaining the physical specifications.

American Ceramic Society Meeting

WEDNESDAY, Sept. 24, was set aside as Ceramic Day at the Exposition, and aside from visitation of the many booths devoted to ceramic subjects in the Coliseum and Armory the American Ceramic Society held its annual meeting under the direction of W. D. GATES, acting as chairman, and CULLEN W. PARMALEE, as secretary. The morning session was called at 10:45 o'clock in a conference room in the First Regiment Armory, and papers were presented in order as abstracted below. The Society is to be complimented on the progress being made through the efforts of its many active members in their combined effort to forward the state of the art to its highest standard.

Superior Refractories

In the presentation of this paper, the author, ROSS C. PURDY assumed that the audience had a clear understanding of present conditions in the ceramic art, because so much has already been published in the journal of the society and so much work has already been done by the universities and by individuals on the methods of testing, etc. The paper presented at the Philadelphia meeting of the A. C. S. on the same subject dealt with the need of the industry for superior refractories.

This is a plea to the American Ceramic Society to initiate, directly or through the agency of the National Research Council, active and thorough researches by a Federal Bureau, of our refractory problems. This recommendation is made in spite of a keen appreciation of the excellent work which has already been completed and at present being undertaken by the Federal Bureaus, the National Research Council, the American Ceramic Society, the Refractories Association, the American Society of Testing Materials and other organizations. Much has been done by our universities and much by industrial concerns. In the presentation of this plea there is no forgetting the advances we have made through the efforts of these several agencies and there is no thought but that these several bureaus, societies, universities and industrial concerns should continue independent researches on refractories as has been their wont, and as they no doubt are continuing, for there are advantages in independent investigations by several organizations each with its peculiar purposes, viewpoints, facilities, etc. Indeed we want more of this dispersion of interest and activity in researches on refractories. It would be well if each of the several bureaus, societies, colleges, etc., would see the great need there is for progressive and aggressive investigations of our refractory problems and each independently initiate and prosecute researches in this, the one branch of ceramics in which we are the most backward in meeting the industrial demands for a better product.

ADVANTAGES FROM A FEDERAL BUREAU

Notwithstanding this keen appreciation of the benefits derived from independent investigations and researches by several, we must recognize the advantages of unrestricted facilities, not alone in expensive and varied equipment to meet every desired requirement, but also in facilities for very accurate observations and for obtaining of trustworthy constants such as can be

obtained only with highly trained investigators and expensive apparatus. We must appreciate also facilities for broad observations not alone in the development and manufacture of refractories but also the industrial needs for refractories. It is very obvious that the most rapid and the most certain progress in the development of refractories can be had only by an elaborate and aggressive investigation, an investigation that is beyond the possibilities if not beyond the scope of independent organizations of small financial resources and limited interest.

BENEFITS WOULD BE NATIONAL AND WORLD WIDE

Then, too, the benefits would not be alone to the manufacturers of refractories, indeed not as much to them as to the users, and to the national and world-wide welfare. It does not require much breadth of thought to realize how dependent is our present-day industrial progress on the development and manufacture of superior refractories, refractories that are superior for the several purposes than those now being employed. Consider for a moment the saving of time and of labor and of metal that is effected by the closed electric furnace over the open-top crucible for brass melting. The electric furnace today is melting less than 1 per cent of the brass used, and yet it is saving a million dollars' worth of zinc metal by reducing its loss from 6 to 9 per cent down to 1 per cent and less. In this one operation alone electric furnaces are not only saving metal but also labor, and at the same time are making the operation more tolerable for the operators. Examples could be multiplied by reference to the many heat-treating operations where with development of new equipment and processes they are effecting economies and bettering operating conditions. But these benefits cannot be fully realized until more suitable refractories are developed. The rapid development and adoption of electric furnaces for a large number of purposes has given rise to an urgent appeal for better refractories. The development and rate of adoption of the electric furnace has been phenomenal, but is greatly retarded by want of suitable refractories.

ADEQUATE SURVEY BEYOND THE SCOPE OF INDIVIDUAL ORGANIZATIONS

There is an urgent need today for an understanding of the qualities or properties that are wanted in each of the large number of industrial requirements. This is no small task. It involves accurate observations and study of possible variations in operation control in the place and under the conditions that refractories are used. It requires a knowledge of metallurgy and of ceramics and above all it requires an appreciation of the relation of costs to service. The most suitable refractory will at the best be a compromise, not alone because of the antagonistic properties that exist but also because of the economics of service involved. An adequate and worth-while industrial survey and research of refractory requirements is so far beyond the possibility and scope of individual organizations, and the benefits derived are so broad, affecting the cost and pleasure of living of every citizen, that it should be made under the auspices of a Federal Bureau, where the expense is borne by general taxation.

ALL CITIZENS SHOULD SHARE IN THE COST

If a discussion of the political economies involved were needed, it could be shown that since our national welfare is more and more dependent on industries as compared to agriculture and since the farm and the industries are today more mutually dependent than at any previous time, all citizens should share in meeting these costs. And if the economy considerations were carried farther, it would be plain that efficiency, relating to time and money expended as balanced against the value of results obtained, would require the employment of the broadest trained investigators, the most accurate and efficient equipment and the most liberal opportunities, all of which are possible only under Federal auspices.

Then, too, there should be extensive research of material resources and manufacturing processes. This should parallel the industrial survey. The two should be closely associated and each be given liberal support. A Federal bureau would secure for this a far better co-operation of the independent organizations than could any other agency, a co-operation that is very essential.

PROGRESS IN THE LAST TWO DECADES

A great deal of progress has been made in the last two decades, not alone in the refractories themselves, but also in our appreciation of the relative value of the chemical and physical means of judging their suitability. We no longer hear of the mistaken and much over-emphasized importance of chemical analysis of clays. We have not, and probably never will, discarded the chemical analysis as being without value. It has a value, for it does give information, but we certainly have less faith today in the empirical methods of Bischof, Seger and Ludwig for estimating the refractoriness of clay from the chemical analysis. We have learned too, that clays having the same chemical analysis but differing in physical and mineral character may have different values for refractory purposes. Indeed it is not uncommon that a freshly mined clay would have but small value for use in refractories, but will be made an excellent clay by merely weathering. This is an instance of the importance of texture and structural strength, factors that are not disclosed by chemical analysis.

We are appreciating more and more that the success of a clay for refractories is as largely dependent upon its physical properties that make it adaptable for manufacturing processes as it is on its chemical and mineral composition. Indeed, the fact is slowly being appreciated that behavior of a clay in the usual fusion test is dependent on physical properties as well as on its chemical composition. No method yet devised can be substituted for the direct fusion test.

Decided progress has certainly been made in knowledge of the method of study and progress has been made in the knowledge of what is essential in refractories, but we have made but little in the actual production for specific purposes. It is not the purpose here to elaborate upon the relative value of the several methods of studying refractory materials and wares or how to produce desired properties in the finished ware. "We are making fair progress in these.

What we need today is the development of refractories that will remain practically constant in their

physical and chemical characteristics through the maximum heat treatment to which they will be subjected when in use. We recognize that when a clay is burned in the firebrick kiln the melting together of its mineral constituents is but partly progressed and that further reactions and solution will take place when subjected to more severe heat treatment. We also recognize the importance of such factors as time, oxidation, etc., in the progress of clay fusion. It is well known that clay that appears equal in the fusion test will differ in load-carrying capacities when subjected to heat treatments much less severe than that required to cause them to deform in the fusion test, and we recognize this as one indication that suitability of a clay refractory is not wholly dependent upon its ultimate fusibility, but in fact is more dependent upon its rate of fusion.

From the evidence that is already before us it is apparent that for the most severe heat requirements, the refractory must have had its physical and chemical properties developed to their maximum; far beyond the possibility of alteration in any heat treatment to which they will be subjected in use. If fused bauxite, fused Alumina, sintered magnesia, or silicon carbide would meet all the industrial high-temperature requirements, there would be no need for this plea for Federal research on refractories. There are needs which these materials will not satisfy and for which such as the spinels, sillimanite, zirconia, etc., are better suited. We have heard much of the possibilities of zirconia as a refractory and have had several industrial trials of refractories made of zirconia, but we know little aside from the fact that we cannot yet produce a zirconia refractory that is economically possible. The same is true of sillimanite, a most excellent refractory of exceptionally low electrical conductivity.

The value of these fused refractory oxides lies not alone in their extreme refractoriness, but also in their constancy in volume, capacity to withstand sudden temperature change, resistivity to chemical and slag reactions, ease with which a desired texture can be produced. Refractory articles with these materials average much higher in desired or required properties than any of the partly fused or partly sintered refractories. No refractory will carry load at high temperatures and withstand the destructive abrasive slagging and temperature changes as will fused bauxite, silicon carbide, sintered magnesia. These same superior values may be found with other materials which have been previously fused. The great problem with them, however, is their production on a cost basis compatible with the service they will give. The solution of this problem is not easy and certainly deserves the serious attention of a Federal bureau, with its extensive capacity to conduct investigations in the laboratory and field.

PLEA FOR CO-OPERATION BY OTHER SOCIETIES

The plea that is being presented is that the American Ceramic Society initiate and secure co-operation by the several other societies in a request for aggressive researches by some Federal bureau in the development and economic promotion of refractories. This will include a definition of the possibilities of clay refractories; an improvement in such as the silica and magnesite refractories, but especially should such a research develop and define the most economic method of production and use of such a superior refractory as can be made of zirconia, the spinels, sillimanite, the ni-

trides, etc. This is no small program. It will tax even a Federal bureau if executed with the vigor that the present urgent industrial demands fully warrant.

This plea is respectfully submitted to the Standing Committee on Research for their careful consideration.

Discussion

Mr. PARKER.—It is known that the Government made inquiries regarding certain clays during the war. The Government should be interested in the establishment of a bureau. Considerable work has been done in Pittsburgh. The execution of Mr. Purdy's ideas would make for great strides in the progress of the art.

Mr. HOWE.—Co-operation is a good lead in this connection. The Manufacturers' Association has found considerable saving would be effected.

Mr. W. D. GATES.—This paper is opportune. I hope this collective effort will be made, as it will cause ceramics to become an art indeed. Interchange of experiences has done more than any other thing for the day-working industry.

Mr. CULENDAR.—Mr. Purdy has made a very valuable suggestion, and if he will furnish us with a copy of his paper we will see that it is published in the journals of the Brick and Tile Manufacturers' Association and the Society of Testing Materials. It is to be hoped this paper will bear fruit.

Mr. SILVERMAN.—The manufacture of lapidolite would be benefited by the research work of such a bureau. When substituted for feldspar it eats through the pot ring in two or three days. There is need for such research in the manufacture of white glass as covered by Mr. Pratt's paper read before the American Institute of Mining and Metallurgical Engineers. The Ceramic Society is indebted to Mr. Purdy for his paper.

Mr. C. W. PARMALEE.—This paper is very interesting and the co-operation desirable. The National Research Council already has such a plan on foot. We should therefore co-operate with it rather than deal direct with the Government. The plan should be put through, but the method is in question. The work might be handled by another agency than by a government bureau. Ceramics is a key industry and the co-operative effort of the American Ceramic Society is a good example to the other institutes and societies.

ANOTHER MEMBER.—We should act immediately while other societies are in session in Chicago, and I move we request our Standing Committee to at once notify the Research Committee of the American Institute of Mining and Metallurgical Engineers of our activity in this direction. Motion was seconded and carried.

Mr. ROSS C. PURDY.—I have tried to express appreciation for the co-operative work already done, but for many purposes the clay refractory will not serve. As regards silicon carbide, slabs 10 in. long by $\frac{3}{4}$ in. thick have stood tests perfectly. Alundum has stood 50 lb. per sq. in. at 1400 deg. C. with knife edges used as supports for test piece. Two materials will not meet all tests required, however.

Mr. LINDBERGER.—Tests of fused bauxide and silicon carbide bear out Mr. Purdy's statements. They are not sufficient for all purposes, however. No. 1 fire clay softens below fusion point and ruins the structure. I suggest the use of superior refractories at vital points in the structure rather than in the entire body in order to strengthen and economize in cost of the work.

The laboratory is a hard place to determine all the requirements. The work should be handled by some bureau and on a commercial scale. Users of brick should be in close co-operation during progress of the investigations. Laboratory tests are good, but a bureau could make severe service tests to meet every condition.

Mr. SILVERMAN.—I suggest we include co-operation in the movement with all the societies.

The motion made previously was so amended.

The Past, Present and Future of the American Ceramic Society

This paper, by Prof. CHARLES F. BINNS, was very interesting. In part he said:

The American Ceramic Society was founded in 1899, at Columbus, Ohio, when a small group of scientific men, interested in the problem of silicate industries, gathered together and formed a permanent organization. Beginning with the report of that meeting a volume of Translations has been published each year for nineteen years. In addition to the annual volume, a Manual of Ceramic Calculations, as an appendix to vol. 11, and the works of Hermann A. Segar, translated from the German, were published.

The subjects which first claimed the attention of the Society were those concerned with the clay-working industries, the properties of clay, the various types of glaze, and the control of kilns. Before long, however, portland cement came in for a share of notice, to be speedily followed by sand-lime brick, glass and enamels for steel and iron. The necessary properties of paving brick were closely investigated, as was also the resistance of porcelain to electric tension. A glance through the early volumes of the transactions cannot fail to reveal the broad scope of the activities of the members and the earnestness of their application.

YOUNG MEN INTRODUCE NEW METHODS

At the opening decade the influence of the younger men began to make itself felt. Of the earlier group none had received training in a college of ceramic engineering. Facilities for such training did not exist. Some of the men had studied abroad, and all had graduated from the school of experience. The new men introduced new methods and contributed valuable enthusiasm. The use of engineering expressions became common and greater accuracy in investigations was manifest. The membership did not increase rapidly nor was the balance held by the treasurer an overwhelming burden. The policy of the Society was conservative. The motto was quality rather than quantity. This was sound practice, because the influence of the schools could not be expected to spread very rapidly and without a thoroughly trained personnel the industries could not greatly improve their methods.

NATIONAL GOVERNMENT INTERESTED

A notable step was taken by the National Government in the year 1909 when, stimulated by the demand for improved processes and fostered by the interest of the members of the Society, a department of ceramic research and development was founded in connection with the Bureau of Standards. Laboratories were opened at Pittsburgh and Prof. A. V. Bleining was placed in charge.

GROWTH SINCE 1912

Up to 1912 there had been but one Local Section organized, the Beaver, later changed to the Pittsburgh District Section. At the annual meeting of 1918, charters were granted to six more, namely, the New York State, Northern Ohio, Central Ohio, St. Louis, New England and Chicago, while the Eastern Section was chartered in 1919. These sections hold meetings three or four times a year and are sources of membership, enthusiasm and general society backing. The four ceramic schools, Ohio State, Illinois, New York and Iowa, have student branches which are usually stepping stones toward membership in the parent society.

The growth in membership was steady but not large until about 1917, when conservatism yielded before a vigorous campaign under the Membership Committee, resulting in an increase of over 200, a movement which has continued up to the present, when there are 1156 members. In 1918 the annual volume of Transactions was superseded by the *Journal of the American Ceramic Society*, with G. H. Brown as editor. There has been a gratifying improvement in this journal during the year and three-quarters of its existence, and it now ranks with the scientific journals of much larger societies.

FORMATION OF DIVISIONS NECESSARY

As a natural result of large accessions of membership there came the formation of divisions. With a body so large it was obvious that every interest could not be adequately represented upon a general program. It was also obvious that special technical questions could best be discussed by small groups of men who were immediately and closely interested in them. The formation of divisions made possible the solution of the problem. There are at present the glass, terra cotta, enamels, refractories, brick and tile, white ware and porcelain, and wall and floor tile divisions. Their organization is being perfected and several have already made notable progress. It is expected that at annual meetings hereafter there will be one or two general sessions, with the remainder of the time given over to divisional meetings.

FUTURE HOLDS PROMISE

The future holds much promise for the Society and for the industry it represents. Conservation of fuel will be studied, labor problems met, electrical energy utilized to the utmost, and the ceramist will seize the materials provided by the bountiful earth and will make them his servants.

DR. TRAVERS, of Great Britain.—The Empire encourages co-operative research of the manufactures, and for this purpose there is a fund of about \$20,000,000 available. There is a non-profit co-operative company formed with the various concerns as members. A company appropriates a sum for certain research work and the government puts up an amount from one to five times as great depending on the nature of the work at hand. The company submits only a balance sheet to the government covering the expenditures, and is not otherwise interfered with. When the project becomes self-supporting the government withdraws its support.

Some Aspects of Scientific Research in Relation to the Glass Industry

Speaking on this subject, Dr. EDWARD W. WASHBURN said in part: Although one of the most ancient of the chemical industries, the manufacture of glass, like most of the other ceramic industries, has been one of the last to feel the influence of modern science. This is of course due largely to the fact that the industry, being older than the science, had necessarily to develop along purely empirical lines. The rule-of-thumb methods, and their accompanying "trade secrets," which characterize the development of a complex industry by this method naturally bred a conservatism of viewpoint which did not easily appreciate the value of scientific research or the advantages of scientific control over the materials and the processes of the industry. Furthermore, it must be admitted that until comparatively recent times the chemistry and physics of high temperatures, such as those prevailing in the most important processes of this industry, were so little developed that the science was scarcely itself in a position to render important service to the industry, such a service, for example, as organic chemistry has rendered to the synthetic dye industry, which is a typical example of a great industry built upon a highly developed scientific foundation and completely under the control of scientific methods and the results of continuous research.

KNOWLEDGE AND ITS APPLICATION INCREASING

With the development of methods of producing controlling and measuring high temperatures in the laboratory our knowledge of the chemistry and physics of high-temperature processes has steadily increased and applications of that knowledge have naturally followed. The stimulus of the war has aided greatly in bringing together the practical man of the factory and the scientist of the laboratory. But in glass making we know *how* today much better than we know *why*. Progress demands that we know *why*. No industry which merely knows *how* is in a healthy condition. The feeling of confidence which comes with knowing the *why* of every step in the manufacturing process carries with it certainty of control, progressive lowering of costs, enhanced protection of the workmen, progress in the development of new and improved products and a degree of insurance against such evils as might otherwise attend the exhaustion or temporary scarcity of certain raw materials, fuels, machinery or other necessary supplies.

In the face of the imperative demands of war, or of the almost unlimited markets created by the destruction wrought by war, the necessity of operating with the greatest efficiency is not felt by an industry as it is in normal times with close competition and a market whose further expansion is dependent primarily upon lower selling prices. This is well illustrated in the case of the first two glass factories to resume production after the evacuation of Belgium by the Germans. These two factories, which I had the opportunity to visit this summer, are located in the same district and therefore subject to the same conditions regarding fuel, common labor and costs of materials. They are both engaged in the manufacture of window glass, for which for some time to come there will be an enormous demand for reconstruction in the devastated regions. In the first factory the glass is manufactured by the

older process in which the "metal" is gathered directly from the furnace on the end of the blower's pipe and then blown into a long cylinder which is cut lengthwise, transferred to the flattening furnace and there flattened into a sheet by a second workman. In this factory the blowers are paid from \$250 to \$300 per month. In the second factory operating under the Foucault patents, the process is entirely mechanical, no labor other than that involved in the firing being employed between the point at which the "batch" is shoveled into the tank furnace and the point at which the completed pane of glass issues from the furnace. The highest paid workman in this plant received about 18 cents per hour. In spite of the apparently great difference in efficiency and in costs of the two methods of operation they are nevertheless both able to operate at a profit in a market where demand and not manufacturing costs is the principal element in determining the price of the product.

WORK TO BE DONE IN INDUSTRIAL LABORATORIES

In industrial laboratories the work to be done may be roughly classified under three headings: (1) routine testing of raw materials and products and similar control work; (2) works problems, including the curing of troubles and the improvement of processes and products; (3) fundamental research to find out the *why* of the operations or to secure quantitative scientific data covering materials, processes and products. In the glass industry almost all of the fundamental research work remains to be done. For example, very little is known of the relations between (1) viscosity and (2) temperature and composition, although viscosity has long been recognized as of great importance in making and working glass. Surface tension and vapor pressure and even density have scarcely been studied at all.

Of the reactions and compounds we know almost nothing. The nature of gases remaining in solution is almost unknown, as well as their effect, if any, on the properties of the glass. Many unanswered questions are referred to, including relations between composition and properties, cause of greenish color resulting from substituting soda for potash, the condition of copper in glass, the cause of pink color from manganese, and red in chrome pink, the function of arsenic. These are only a few of the questions recently brought to my attention by an authority on colloid chemistry.

HOW RESEARCH MAY BE PROSECUTED

There is thus no lack of chemical and physical problems in connection with the glass industry whose solution requires only the painstaking work of trained investigators. It is not enough, however, merely to point out the great need of fundamental research in this field; it is necessary that definite steps be taken to prosecute this research as vigorously as possible. Now, there are three types of laboratories in which research of this nature might be carried out. First, the research laboratories of the industry itself. These laboratories, while as yet few in number, may be expected to grow in number, equipment and personnel, and a portion of their resources should be devoted to some of the more fundamental problems common to the industry as a whole, as a part of their contribution to the general advancement of those branches of the physics and chemistry underlying the industry. Secondly, the government laboratories and the laboratories of research foundations, such

as the Geophysical Laboratory. These may be expected to continue their work along these lines and should receive the support of the industry in their efforts to extend their facilities for such work. Thirdly, the laboratories of the ceramic departments of the universities. Now although we have some half dozen departments of ceramics in the country at the present time, these departments have grown up around and been fostered by the clay industries and have as a natural result confined most of their activities in the past to these branches of ceramics. There exists nowhere in the

United States a single professorship of glass technology. I believe that no one of the institutions at which a department of ceramics exists is financially able at the present time to expand its activities.

SCIENTIFIC LEADERSHIP PASSING FROM UNIVERSITIES TO INDUSTRIAL RESEARCH LABORATORIES

In the past the industrial world was content to rely entirely upon the universities for the advancement of science, but today there are many signs that scientific leadership is passing from the hands of the universities to the hands of the great industrial research laboratories and the privately endowed research foundations. Scientific research is becoming more and more costly

and the universities as organized at present can no longer compete on terms of equality with the efficiently organized and adequately financed industrial and endowed research laboratories.

Thus, although no longer entirely dependent upon the universities for scientific research, the industrial world is and must continue to be entirely dependent upon them for the training of its technical personnel, and a part of the responsibility for seeing that such training is provided must in the future be accepted by the industries. Although the Sherman law forbids the formation of combinations in restraint of trade, there is, I believe, nothing in that act which forbids the formation of combinations within an industry for the purpose of uniting on a program for furthering research on fundamental problems and for aiding the universities of the country in the work of training the technical personnel required by the industry.

The afternoon session was opened at 2.45 p.m. at the New Southern Hotel. Lantern and other arrangements were provided by the local section.

Twenty-three Types of Optical Glass

ROBERT J. MONTGOMERY, the author of this paper, said it was the first article within his knowledge that contained a general survey of the subject of optical glass as regards its technical classification. He continued:

By the word optical we mean those glasses which are selected for certain purposes because of their behavior toward transmitted light. This behavior is primarily due to the composition of the glass and not to its shape. Practically all of these glasses are silicates. There are a few special glasses containing no silica, as borates and phosphates, but they are of minor importance as far as quantity of glass manufactured is concerned. Each constituent has an effect on the index of refraction and the dispersion of the glass, and these two properties identify the glass as being of a certain type. Glasses not called optical glass are those made to meet some other requirement than that of index of refraction and dispersion. These will include ordinary soda-lime and lead glasses, in which the composition may be changed to obtain satisfactory melting qualities or in thermometer glass, where the coefficient of expansion is important. The main difficulty in making optical glass is in obtaining the required optical properties and at the same time so combining the constituents and handling the material that a good quality of glass will result.

A study of published information combined with our practical experience in the manufacture of optical glass brings out that: (1) All the glasses may be plotted on co-ordinate paper, allowing the dispersion to be represented by the horizontal distance and the index by the vertical distance; (2) that the glasses fall into natural groups in the field plotted and may be divided into types according to composition; (3) that there are 23 ordinary types of optical glass, each type embracing a number of glasses quite similar in optical properties, composition and method of manufacture; (4) that the composition of the glasses may be divided into two divisions: (a) Basic oxides affecting the optical properties, and (b) control chemicals which affect the melting behavior. The basic oxides are SiO_2 , K_2O , Na_2O , CaO , BaO , PbO , ZnO , B_2O_3 , etc., while by the control chemicals are meant the proportioning of carbonates, nitrates, chlorides and sulphates or the use of As_2O_3 and Sb_2O_3 to obtain good melting conditions.

The illustration shows the fields occupied by the various types of glass with an index 1.45 to 1.800 and dispersion value from 20.0 to 70.0. These are listed in Table 1. The ones marked with a star are now being successfully made in commercial quantity in this country.

TABLE 1

1	Borosilicate crown	13	*Barium light flint
2	Borosilicate crown, high Na	14	*Barium flint
3	Crown of low Na	15	Dense barium flint
4	Light silicate crown	16	*Telescope flint
5	*Ordinary crown	17	*Extra light flint
6	*Telescope crown	18	Borosilicate flint
7	*Ordinary crown of low Na	19	*Ordinary light flint
8	Soft silicate crown	20	*Ordinary flint
9	Zinc silicate crown	21	*Dense flint
10	Barium silicate crown	22	*Extra dense flint
11	*Dense barium crown	23	Densest silica flint
12	*Densest barium crown		

It will be noticed that we have now made in this country 12 out of the 23 ordinary types of optical glass. Most of those which have not yet been made have not been attempted because of lack of demand for the glass.

In making this survey of optical glasses only the general compositions are discussed. There is a natural field in which we normally use each constituent. This does not mean that such constituents may not be used outside of its natural field to control the optical properties or the quality of melting. The amount used in such cases is small and does not affect to any considerable extent the type of the glass. When it is desired to develop a new glass with new optical properties its composition can be roughly determined by interpolation between known points in the fields, and the necessary chemicals are definitely shown except in those cases where unusual materials are used. Special glasses not containing silica, as borates and phosphates, are not considered in this paper, and a few special ones within the field given are left out, as they do not bear directly upon the general subject.

Discussion

Dr. HOSTETTER.—Mr. Montgomery is quite right in stating that the band on the left of the chart should really be a line. We made a similar diagram some time ago and thought it would be absurd to give names to various types of glass, so attempted to describe each by its index number. Lens makers, however, are interested in *partial* dispersions, therefore the numerical symbol could not be used. We finally gave up, but decided something more definite in classification should be evolved.

Mr. MONTGOMERY.—I agree this classification is indefinite and a new one should be based on partial dispersion. The names we have given, however, are generally used and this chart, being only for *general* classification, is the best we have at present.

Dr. TURNER, secretary of the British Society, is called upon and while having nothing to say on the paper brings hearty greetings of his society. Appreciates welcome he has received in the United States and the work that is being done between the two societies. Wants to make arrangements for the joint meeting next year. Feeling the need for information on ceramics, the British Society has projected the publication of a series of pamphlets for the benefit of the industry.

Other Papers

Brick and Tile, DONALD F. STEVENS.—I have been requested to speak as a representative of the Brick and Tile Division. This has been most recently organized

because if not done the work would have been buried by other activities of the Society. The Ceramic Society has done much and can do more for the brick and tile industry.

Directed toward chemical uses, it was originally used only for chemical stoneware, but we find now that the chemical plant puts it to all sorts of uses. More has been done in this connection than ever before during the last year. When the speaker visited the government plants at Sheffield, Ala., and saw the extensive use of ceramic ware and brick in the acid and ammonium nitrate plants he was glad to be in business. Here the most beautiful specimens of brick and tile work that he had ever seen in the construction of coolers, acid towers, tank linings, floors, flues and innumerable other places where proof against deterioration from acid and alkali solutions was necessary, were in evidence. This sort of work has been going on for four or five years and it is up to research parties to find new uses for brick and tile.

The value of fuel is steadily increasing. The ceramic industry consumes fuel in the greatest quantities of any except the steel industry. Much work needs to be done on more efficient use of fuels. The effects of alkalies and lime in driers and kilns must also be studied.

The brick and tile manufacturers are coming to appreciate the efforts of our society and we should secure more of them for membership. They are alive to its benefits, appreciate the work the universities are doing and will co-operate heartily with us in the activities of the future.

Artificial Sillimanite, A. MALINOVZKY.—This paper contained a lengthy technical discussion of the method evolved by the author for producing artificial sillimanite, complete with chemical reactions, numerous lantern slides and a thorough explanation of the method of operation of the furnace. Analyses of resulting products showed progress of the reactions and microscopic views exhibited the long needle-like crystalline forms of the physical structure.

The Making of Pottery, FREDERICK H. RHEAD.—The most commonly known ceramic decorative processes are divided into ten broad groups. Each group is briefly reviewed with particular reference to typical examples ranging from the primitive or early works to modern productions. The processes of primitive, medieval and modern potters are discussed from a practical point of view. A description of various methods, tools and the physical condition of the materials is given, while the artistic and commercial developments are suggested by illustrations of examples referred to in the paper.

The groups enumerated are as follows:

First, incised and etched surface decorations, examples referred to: Early British, Chinese, Italian Sgraffito, Modern Porcelain, Cast Sgraffito, and commercial tile treatments.

Second, modeled and relief surface decorations. Examples referred to: Ancient Chinese, Roman, Eler's style, Palissy, German Stoneware, Wedgwood, Modern.

Third, slip processes. Examples referred to: Old English, Toft, European, Modern Slip Decorations, Pate-sur-pate.

Fourth, underglaze processes. Examples referred to: Grecian, Italian, Majolica, Chinese, Japanese, Modern European, commercial processes.

Fifth, glaze manipulation. Examples referred to: Chinese, Persian, European, Modern.

Sixth, plain glaze treatments. Examples referred to: Chinese, Modern.

Seventh, lustre processes. Examples referred to: Persian, Spanish, Modern.

Eighth, overglaze decorations. Examples referred to: Chinese, European, Modern.

Ninth, sculpture. Examples referred to: Chinese, Italian, European, Modern.

Tenth, architectural pottery. Examples referred to: Babylonian Bricks, Della Robbia, Mexican, European, American, Italian Mosaic.

Buy on Analysis, DR. ALEXANDER SILVERMAN.—This paper deals with the variations in composition of soda ash, pearl ash, limestone, quick lime, burnt lime, sand, litharge, niter, salt cake, zinc oxide, alumina, china clay, feldspar, fluorspar, cryolite and other minerals and chemicals used in the manufacture of glass. It illustrates the wide range of possibilities in composition and emphasizes the necessity for purchasing one kind of material for a given manufacturing purpose. The author points out that there is not so much danger in the difference of composition as in substituting a material of one composition for that of another formerly employed in glass making at a given factory without making necessary corrections. The paper further emphasizes the importance of the density of material such as soda ash and the mechanical analysis of sand calling attention to variations in grain size which might produce different results in glass manufacture.

The Manufacture of Optical Glass, DR. J. C. HOSTETTER.—In 1885-90 George Macbeth successfully started the manufacture of optical glass in the United States, but the industry was not really developed until the advent of Bausch & Lomb in 1912 and the Pittsburg Glass Co. and Spenser Lens Co. in 1914. With this somewhat restricted production as a basis, the industry received a tremendous impetus due to the requirements for a large tonnage in military uses.

It was necessary to produce large quantities of containers for melting the glass, and the Bureau of Standards and U. S. Geological Survey aided in obtaining the special clay needed. These crucibles are slowly constructed by hand and heated for seven days at a temperature of 1000 deg. C. They are then placed into the furnace for filling. The Armour Fertilizer Co. furnished a fine grade of potash containing only from $\frac{1}{2}$ of 1 per cent chloride down to 0.0002-0.0003 per cent. The pots are used for one melt only. The heat is regulated through optical pyrometer readings.

Homogeneity is the main requirement in the manufacture, and the mass is constantly stirred by clay tubes both hand- and machine-operated. The stirring continues during the heat and at intervals while cooling. The mass is finally cooled and broken into large pieces, of which only the best are selected. The first rejection consists of about 80 per cent of the total, and 50 per cent of that is rejected on the second inspection. After many subsequent inspections the finest product is pressed into final form and shipped.

The United States probably doubled the production of the Jena output during the war period, starting from a negligible production at the outbreak

The Menace of the Postal-Zone Law

By FRANK W. MONDELL

Representative in Congress for Montana

I AM opposed to the zone system for the dissemination of news, ideas and information because I am of the opinion that the establishment and maintenance of such a policy would, in the long run, have a most unfortunate, harmful and regrettable effect upon the American people.

If we are to maintain peace, order and justice under the institutions of free government within our borders, we must have a homogeneous people guided by the same principles and inspired by the same ideals. This condition essential to the maintenance of free government can only be secured by the widest possible circulation of those instruments and instrumentalities which inform, mold and affect public opinion.

Any policy which tends to make us provincial or parochial as a people, which tends to build up zones of influence and information, is a policy not only harmful but one that long continued and widely extended would prove fatal to free institutions. On the other hand, a policy which makes equally available to the people in all parts of the country the journals and magazines which convey information, carry current argument, analysis and entertainment, tends to maintain those conditions essential to our institutions.

Those whose views or arguments for the zone system are based primarily or largely on its effect, or alleged effect, on postal revenues, or the profits of the publishing business, fail utterly to grasp or realize the larger and infinitely more important aspects of postal systems as they effect the national life. If it be a fact that the flat postal rate on newspapers and magazines has been unduly low, that is a matter for consideration by the Post Office Committee, having in view the traditional policy of the American people. The fact that some people have been able to make a considerable amount of money in the newspaper and magazine business is, of course, one of the matters that a committee would consider in this connection, but it is by no means conclusive that a policy is wrong because some people have been able to make money under it—many having the same opportunities and privileges failed utterly.

The demand for the establishment and maintenance of a zone system is particularly lame and illogical when it is made by those who are urging a flat rate of one cent on letters. Such people to be logical should insist upon a zone rate for letters as well as papers and periodicals. Neither is the argument for a zone system strengthened by exaggerated statements of losses to the postal revenues under a flat rate. Undoubtedly the former flat rate did not wholly reimburse the postal revenues, but the most superficial examination of the matter renders ridiculous exaggerated statements of alleged losses. To the argument that publications enjoying the second-class rates are devoted more or less to advertisement, I offer the suggestion that a national dissemination of attractive advertisements is not without its educational benefits.

I have neither urged nor considered this as a party question. I urged this repeal before the previous Democratic Congress, as I shall before the present Republican Congress—not on party or partisan grounds, but on the broad platform that such a policy tends to circumscribe and provincialize our national life to our great haven as a people.

Preparation of Fuller's Earth

By W. C. PHALEN.

The bleaching action of fuller's earth is independent of its chemical composition, but depends entirely upon its selective power of absorption or capillary action. Therefore the slight variations in the analyses of the earth bear no relation to its bleaching powers. As is well known, the main use of fuller's earth is for the bleaching of petroleum oils, and the gravity method is used in preference to agitation. The main object sought is to get the lightest possible color with the most prolonged use of the earth, the renewal of which is accomplished by burning.

In a recent article by C. R. Siegfried (*National Petroleum News*, Aug. 20, 1919, p. 38) it is pointed out that the blame for poor filtering is often placed on the earth, whereas it is due to improper manipulation. It is important to bear the following factors in mind: (1) The longer the column of earth, the better the bleach and the lighter the color of the oil, other conditions being equal. (2) The coarser the earth, the more rapid the flow and the poorer the bleach, other conditions being equal. (3) The higher the temperature, the faster the flow and the poorer the bleach, other conditions being equal. (4) As a corollary, filtration should take place at the lowest temperature at which the oil works well. (5) The oil which is being filtered must be fluid enough to be acted on mechanically by the internal structure or pores of the earth, for it is in these pores that the coloring ingredients of the oil are retained, and not in the spaces between the grains themselves. Each particle of the earth, therefore, has its own work to do independent of the others.

The preparation of the earth prior to its going to the filtration plant is of great importance. It follows that the workman firing a burner for fuller's earth is the party who breaks or makes the life of the earth in the filter. The preparation is done by burning and the first burning is the most important of all.

All fuller's earth is hygroscopic, that is, it absorbs moisture from the air. During the first burning it is essential to get rid of this absorbed moisture and also the chemically combined water. The quantity of water varies from 10 to 15 per cent, and this must be expelled before the earth goes to the filter. Organic and volatile salts are also expelled during the first burning, and calcium carbonate is converted to caustic lime.

It has been found by experiment that the best temperature for the initial burn is 600 to 700 deg. F. At this temperature all moisture is expelled and there is no danger of fusion or incipient fusion, whereby the particles are glazed, the pores closed and the absorptive power lost.

The second burning is almost as important as the first, as there is a greater tendency for the grains to fuse and stick together than in any subsequent burnings. It is, therefore, run more slowly than the first or subsequent burnings, and at a temperature of 1050 to 1100 deg. F. In subsequent burns with Florida earth, the proper temperature has been found to vary from 1100 to 1200 deg. F. Any temperature above 1200 deg. causes a loss of filtering power. It was found on the fourth burning of two samples of earth from the same filter that of two samples—the one burned at 1100 deg. F. and the other at 1400 deg. F.—the overburn of 300 deg. F. caused a loss of filtering power of 30 per cent.

Synopsis of Recent Chemical and Metallurgical Literature

Some World-Wide Problems of the Chemical Industries.—Dr. H. GROSSMANN gives in the Dec. 4, 1918, issue of *Technische Rundschau* a review of some of the world-wide problems of the chemical industry. He states:

The obtaining of sufficient quantities of food is intimately dependent on the manufacture of great quantities of artificial fertilizers. This can be attained only by working with all available forces on the problem of supplying European and American farmers with potash salts, phosphates, and nitrogenous fertilizers. The large and productive potash deposits of north Germany assure the Germans of a sufficient supply of these for the present and the future. These must be regarded as the cheapest of all artificial fertilizers.

Still greater achievements have been made during the war in the production of nitrogenous fertilizers. It is now generally known that without the great successes of present science and technology in the manufacture of artificial saltpeter, synthetic ammonia and calcium cyanamide, the great war would have been lost by Germany within a few months of its beginning. England, France and recently even the United States took up energetically the same questions, in all cases the governments actively supporting these industries. In the next few years we can even count on an oversupply of these nitrogenous fertilizers, as a result of this great activity during the war.

The manufacture of calcium cyanamide in such large quantities gave rise to a greatly increased production of calcium carbide and it is in place to consider whether this latter fact may not lead to the manufacture from it of alcohol and acetic acid cheaply and in large quantities. Such industries may attain great importance in countries having large cheap water powers, such as Switzerland and Scandinavia.

Another important world problem is the more rational and efficient utilization of our fuels. We must particularly produce liquid hydrocarbons, which will replace petroleum and its derivatives, such as benzene, motor oils, lubricating oils and paraffine. On the basis of what was accomplished in Germany during the war in the way of using bituminous and brown coals so as to obtain from them products similar to those mentioned, we may predict that further advances in this direction are sure to be made. Even as it stands at present, Germany is assured a greatly increased supply of benzol from these domestic fuel plants, while great quantities of tar and tar oils, fuel oils and motor oils are also made by the same processes. These tar oils were highly useful during the war in taking the place of lubricating oil from petroleum, and thus they were in a position to keep their large gas machines and motors in operation.

Great hopes are likewise being based on the low temperature distillation of bituminous and brown coal in gas producers, producing new varieties of tar which are good for lubricating and internal combustion motors. This is a very promising field, which has been actively followed up by several German firms and institutes of research.

The technical use of hydrogen gas under pressure appears also to be particularly valuable, such as in the Bergin process of the Consortium for the Chemistry of Carbon and in the tetralin process of the Tetralin G. m. b. H. of Dessau. Tetraline, or tetra hydro-naphthalene, is a very useful material, as in the lacquer industry. It has become possible to thus convert solid naphthalene into a fluid hydrocarbon with numerous new applications.

England and America have certainly begun during the war similar developments in carbon chemistry and the utilization of fuels, and it cannot be doubted that this fact alone would make it absolutely necessary for Germany to pay the greatest attention to the progress of science and technology in foreign countries. The former German Minister of Education, von Trott zu Zolz, was therefore quite right when he said, as far back as January, 1917, in his report on the furthering of foreign study, that a greatly increased knowledge of what foreign nations were doing was an absolute necessity. From the present standpoint, such a continuous and close study of foreign methods appears more necessary than ever.

In the present difficult times none of us should grow pessimistic or lose courage for his work; we should see that in the near future our spiritual and material development is going to continue. This is particularly true of the chemical industry of Germany, which before the war was recognized by all the world as pre-eminent. This being so, we should recall the very true words printed by the *North American Review* in 1893, which are well worth quoting in concluding these remarks:

"That country which has the best chemists will eventually become the richest and most powerful. It will possess at the lowest prices the best food, the best manufactures, the best weapons, and lose the least in production. Its people will make the best possible use of the natural resources of their land, because of universal hygiene they will enjoy the best health, and they will be least dependent on other nations for supplying their needs. The instruction of the people in chemistry and other natural sciences is therefore to be regarded as the best investment of a people's capital, since in the future the competition for place among the nations will depend principally on their achievements in scientific and technical chemistry."

The Increased Value of the Taylor System for Post-War Times.—The Jan. 1, 1919, issue of the *Technische Rundschau* contains an interesting article by ENG. WINTERMEYER on the application of the Taylor system for post-war times, with special reference to Germany. He remarks:

The quick and successful application of this system to American industries has given them a great advantage in international competition. To catch up to the Americans in this field, and if possible to surpass them, should be the aim of all who are active in industry and trade.

For reaching the lowest cost of production, it is necessary to divide up the work into as many different parts as possible. Each workman thus becomes highly skilled in a very small field, and gives his whole attention to perfecting it; in other words, he becomes a specialist, with great knowledge and ability in a narrow field. Each workman must be assigned to that particular part of the field for which he has the greatest inclination and aptitude. He must be contented and take

pleasure in his work; only thus can the best ends be attained. A skilled workman should never be assigned a task which a less skilled or ordinary laborer can do. The average workman must be relieved as far as possible from unnecessary mental work; this should be done for him by others who are better prepared for it by inclination and education. The scheme therefore involves a fundamental study of each worker to determine his aptitudes and capabilities.

The mental work must be done outside of the workshop, in a particular bureau where a corps of educated men are placed. These do the preliminary researches and calculations leading up to the mechanical work; they are also specialists, giving in each field the best possible service. They are always in close touch with the workman, and when they bring the workmen under their care forward satisfactorily, they are correspondingly rewarded. They therefore work hand-in-hand with the workmen.

In each division of the work, the workmen must be taught to practice simplification and improvement of their particular part. Each working motion must be studied to see if it cannot be done in a simpler and more effective way. Every unnecessary, purposeless movement or action is to be cut out, leaving only the absolutely necessary working motions which can attain the desired end.

A very important part of the system is the standardization of parts. The greatest care is given to selecting the most readily producible parts which go into the construction of a complex article. The question is how far standardized parts can be thus used. If, for instance, a certain system of screws is standardized, then the constructor must endeavor to use these normal forms wherever possible, thus saving time, money and attention. This does not limit the free activities of the designing engineer; the opposite is the case. How important this idea is, is well shown by the recent creation of the Standardization Committee of German Industries.

In actual application of the Taylor system it is absolutely necessary that the individual workman be fully contented; only so can the best results be attained. This is attained most completely on the basis of the manner and amount of payment for work done. This is done absolutely fairly and impartially. A single foreman does not determine the wages, but this is done by the "works bureau," on the basis of their own experiments and experience. This bureau makes most complete investigations of the time necessary to perform the individual movements or operations of which the work consists. These studies form the basis of the time assigned to each piece of work. Adding to this necessary time a certain percentage for rest or relaxation, there results the average time which should be allowed for the operation. The percentage assigned for relaxation must also be studied, and assigned such an amount that the workman can work through his shift without becoming sleepy or exhausted.

The workman who reaches the output thus determined is given high wages; if he exceeds it, still higher, if he comes short, below a certain standard, he is paid accordingly. Whether he reaches the high standard or not depends on his industry and skill. The average workman can produce much more working under the Taylor system, and this improvement is made profitable both to himself and to the employer.

Recent Chemical and Metallurgical Patents

British Patents

Complete specifications of any British patents may be obtained by remitting 25c. each to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

High-Speed Tool Steel and Other Steel Alloys.—High-speed tool steels and other alloy steels containing chromium, vanadium, tungsten, titanium, or the like are made by a single aluminothermic reaction of a charge containing aluminum, magnesium, silicon, or like reducing elements, and ores, oxides, or salts of chromium, etc., iron, and carbon, without the use of a separately prepared bath of molten iron or steel. The carbon may be present as ferrochromium or other alloy, and some high-speed or like steel scrap may be used. For example a steel alloy containing carbon, cobalt, chromium, vanadium, tungsten, and manganese may be prepared from a charge containing separately prepared aluminothermic iron, tungsten and cobalt mixtures, wrought iron or mild steel, carbon-free ferrovanadium, and ferrochromium containing about 8 per cent of carbon. (British Patent 123,102—1918. W. L. TURNER, Purley Chase, Atherstone, Warwickshire. April 9, 1919.)

Extracting Metals and Alloys.—Aluminum alloys containing zinc, copper, iron or other metals and 65 to 97 per cent of aluminum, with or without small amounts of magnesium, silicon, calcium, or the like, are used instead of commercially pure aluminum in thermo-aluminic mixtures for use in the manufacture of metals and alloys, or in the production of steel alloys by the process described in Specification 123,102—1918. The aluminum alloys may be melted, cast and crushed. In some cases, part of the aluminum alloy in the mixture may be replaced by pure aluminum, magnesium, silicon, or the like. In using the mixture, the parts of the charge near the points of initiation of the reaction may be more finely divided than the remainder. (British Patent 123,103—1918. W. L. TURNER, Purley Chase, Atherstone, Warwickshire, and H. A. BLACKWELL, Whyte House, Bispham, Blackpool. April 9, 1919.)

High-Speed Tool Steel and Other Steel Alloys.—High-speed tool steel hammerscale is used as an ingredient of the thermo-aluminic mixture for making high-speed tool steel, magnet steel, or other steels containing tungsten, chromium, vanadium, titanium, cobalt, molybdenum, and the like, according to the process described in Specification 123,102—1918. For example, a mixture may be used containing 100 lb. of the scale, 4½ lb. of ferrochromium containing about 60 per cent of chromium and 8 to 10 per cent of carbon, 10 lb. of wrought iron or mild steel, and 28½ lb. of aluminum. Silicon and manganese, if required in the steel, are added as ferrosilicon and ferromanganese preferably after the thermo-aluminic reaction. (British Patent 123,113—1918. W. L. TURNER, Purley Chase, Atherstone, Warwickshire. April 9, 1919.)

Chrome Steel.—A mild chrome steel containing 12 to 15 per cent chromium and less than 0.1 per cent of carbon, or a rustless chrome steel containing 0.2 to 0.4 per cent of carbon, is produced as described

... Specification 123,102—1918, by the thermo-aluminic reaction of a mixture of chrome iron ore or other chromium and iron bearing materials and aluminum, magnesium, silicon, or the like, or scrap aluminum alloy (say 30 per cent aluminum), the mixture containing also, in some cases, some metallic iron and in the case of the second mentioned steel, sufficient carbon. (British Patent 123,104—1918. W. L. TURNER, Purley Chase, Atherstone, Warwickshire. April 9, 1919.)

Ferrochromium.—In the production of carbon-free ferrochromium by the aluminio-thermic process, potassium or sodium bichromate or chromate is added to the mixture of chrome iron ore and aluminum or other reducing agent. The mixture may be preheated. (See British Patent 123,104—1918.) (British Patent 123,105—1918. W. L. TURNER, Purley Chase, Atherstone, Warwickshire. April 9, 1919.)

Acetates.—Aqueous solutions of acetic acid are extracted by organic solvents insoluble in water (ex. benzene or toluene) and the extract is neutralized by a solution of basic lead acetate, milk of lime, or alkalis. The solvent is separated from the neutralized solution and used again for extracting the acetic acid solution. The process may be applied to the dilute sodium acetate liquors resulting from the manufacture of chrome yellows from lead acetate; the sodium acetate liquor is acidified with sulphuric acid and extracted with benzene, which is repeatedly circulated between the acid solution and a solution of basic acetate of lead or milk of lime. (British Patent 122,953—1918. E. F. MORRIS, Holly Bank, Roby, near Liverpool. April 9, 1919.)

Obtaining Lead Electrolytically.—Spongy lead, suitable for use in making battery plates, is obtained by electrolyzing a caustic alkali solution with an anode of lead or lead peroxide, for instance an old battery plate, and a cathode of another metal such as zinc and collecting the metal floating at the surface of the electrolyte. The electrolyte may contain 20 per cent of caustic potash. A suitable current density at the anode is 12 amp. per sq.ft. The product is impregnated with hydrogen from the cathode, and may be freed therefrom by compression if desired. It is washed successively in acid and water. (British Patent 123,587—1918. V. G. JOURIEFF, 43 Victoria Road, Chingford, Essex. April 24, 1919.)

Obtaining Metals and Alloys Electrolytically.—In the production of metals and alloys, such as tin, copper and bronze, in the form of paste or sludge, suitable for coating paper, anodes formed partly of the metal and partly of insoluble material such as hard graphite are used to prevent an increase in the quantity of metal in solution. The ratio of the areas of the soluble and insoluble parts of the anode may be adjusted by raising or lowering them. Further regulation may be obtained by immersing in the electrolyte at intervals pieces of the metal, not connected in circuit. The electrolyte may be circulated through a series of vats, the soluble or insoluble anodes being in the same or different vats. Means for regulating the electric current or liquid flow through individual vats may be provided. A heating or cooling coil may be arranged in the liquid path. In the production of tin, the electrolyte may contain 2.5 g. of tin and 50 g. hydrochloric acid per liter; the cathode current density may be 60 amp. per sq.dm.; the ratio of the

area of the soluble anode to that of the insoluble anode may be 2 : 4, and the temperature not above 28 deg. C.—say 20-21 deg. C. (British Patent 124,006—1918. B. LEECH, 77 Powell St., Macclesfield, Cheshire, and H. & L. SLATER, Harter St., Manchester. May 7, 1919.)

Phenolaldehyde Condensation Products.—In the production of resinous condensation products from phenols and aldehydes, ammonium salts of volatile organic acids (formic, acetic, propionic, butyric, valeric, etc.), ammonium salts of organic acids which decompose to phenols or cresols, salicylic acid or ammonium bicarbonate are used as condensing agents. The process is carried out by heating the reagents until the condensation product has formed, removing the upper aqueous layer from the product, allowing the residue to stand, and cooling to separate more water, and to drive off all the water. Lime, baryta or magnesia may be added in the last stage to assist in removing the condensing agent. Fatty acids or their salts, resins, gums, waxes, rubber, etc., may be incorporated in the product. (British Patent 124,011—1918. R. E. DIOR, 93 rue Thiers, Boulogne sur Seine, France. May 7, 1919.)

Preparation of Aluminum Chloride and Sodium-Aluminum Chloride.—Calcined clay and sodium or potassium chloride are heated in a rotary furnace to bright redness and vapors of arsenious oxide are passed over, to form sodium or potassium aluminate, silica, and vapors of arsenic trichloride. The aluminate is separated by solution in water, and carbon dioxide is passed through the solution, forming sodium or potassium carbonate, and precipitating alumina. The alumina is mixed with coke and in some cases sodium chloride, and formed into briquettes, which are heated and treated with gases containing chlorine formed from the arsenic trichloride. Aluminum chloride or the double salt sodium-aluminum chloride is formed and distilled. The flue gases containing vapors of arsenic trichloride formed in the first operation are treated with steam to form arsenious oxide, which is condensed by cooling, and hydrochloric acid gas, which is oxidized to yield chlorine by admixture with air and passage over heated catalytic surfaces such as small balls of clay impregnated with copper chloride. The gases containing chlorine are washed with water to remove hydrochloric acid and are dried. (British Patent 123,243—1918. E. E. DUTT and P. C. DUTT, Jubbulpore, Central Provinces, India. April 16, 1919.)

Continuous Zinc Extraction.—The zinciferous ore is mixed with bituminous coal, the mixture subjected to a low-temperature coking, out of contact with air, expelling thereby the superfluous hydrocarbons and water vapors. The mass is powdered and fed at the top of a retort comprising 3 sections. The smelting takes place in the middle section of the retort. The zinc vapors pass out through a branch in the upper section to a condenser in which a hood floats in the metallic zinc and protects it and the fumes from oxidation. The residue from the middle section, which will contain in the metallic form any lead or iron originally present in the ore, etc., passes into the third (lower) section of the retort, from which it may be discharged periodically or continuously, admission of air to the retort being prevented. (British Patent 122,688—1918. J. ARMSTRONG, 5 Victoria St., London, April 2, 1919.)

Publications in Europe and Africa.

A list of newspapers, trade journals and other publications in the principal cities of Europe and Africa has been prepared, from names submitted by American consular officers and representatives of the Bureau, for the benefit of firms interested in foreign advertising. This list may be obtained from the Bureau of Foreign and Domestic Commerce or its district and cooperative offices by referring to file No. 9858.

The Gold Production of Australia.

The gold production of Western Australia continues to show a steady decline. During the six months ended June 30, 1919, the total Australian production amounted to 573,279 fine ounces, of which Western Australia furnished 410,428 oz. For the first six months of 1918 the Australian production was 641,911 oz., the State of Western Australia furnishing 443,983 oz. During the first six months of 1917 the total production amounted to 727,995 oz., of which amount Western Australia furnished 490,466 oz.

It is stated that the cause of this decline is increased working expenses due to high wages and the high cost of machinery and materials. It is not expected that much, if any, improvement can be looked for in the immediate future.

The Chemical Warfare Service.

Senator Chamberlain in his criticism of the Army reorganization bill comments as follows on its failure to continue the Chemical Warfare Service as a separate entity:

"No provision is made in the pending bill for the maintenance of that important service as developed and organized during the recent war, but it is understood that it is the purpose of the Secretary of War to assign it permanently to the Engineer Corps, under the general powers proposed to be conferred upon the President by this bill.

"In consideration of this subject it is of the first importance to bear in mind that such a service must have two separate and distinct functions. One of them is scientific research and the development, production and procurement of necessary materials. The other function is the application of those materials by appropriate troops to military uses, just as the materials developed, produced and procured by the Ordnance Department are applied to military uses.

"These two functions of a Chemical Warfare Service should not be combined in one organization or under one head, because there are no officers in the Engineer Corps or elsewhere in the Army whose training and practical experience as chemists fit them either for the performance or the intelligent supervision of the scientific duties of chemical research and production.

"There should be established in the Army a department of chemistry, along the lines of the Medical and Ordnance Departments, to be filled from top to bottom with expert professional chemists.

"To this department should be assigned all duties pertaining to the scientific research required, and to the development, production and procurement of all materials needed for the purposes of chemical warfare, such materials to be supplied to appropriate troops for application to military uses, including the making of the necessary experiments with regard to such uses.

"To this department should also be transferred, as far as practicable, all work of a chemical nature now done in or under the various bureaus of the War Department."

Personal

Dr. JEROME ALEXANDER, well known for his contributions on colloid chemistry, is confined to his house in the country at Ridgefield, Conn., by illness. The latest reports concerning his condition are favorable.

Lieut. C. H. HAZARD, recently discharged from the Chemical Warfare Service, is now with H. A. Metz & Co., Inc., and the Consolidated Color & Chemical Co., in its purchasing department.

Lieut.-Col. ELMER K. HILES, formerly of the Engineers, A.E.F., is now manager of laboratories, Pittsburgh Testing Laboratory, Pittsburgh, Pa.

Mr. JACK J. HINMAN, JR., formerly captain in the Sanitary Corps of the A.E.F., has returned to his pre-war duties as water bacteriologist and chemist to the Iowa State Board of Health and assistant professor of epidemiology in the State University of Iowa.

Mr. JULIUS B. KOHN, formerly employed by the U. S. Public Health Service as organic chemist, doing research work under the direction of Dr. Julius Stieglitz of the University of Chicago, is now connected with the Mallinckrodt Chemical Works, St. Louis, Mo., as research chemist.

Professor GILBERT N. LEWIS, dean of the College of Chemistry, University of California, formerly lieutenant-colonel in the Gas Service, A.E.F., has been decorated Chevalier of the French Legion d'honneur.

Mr. VICTOR E. NELSON, associate in chemistry, Johns Hopkins University, has accepted a position as assistant professor in charge of physiological chemistry at the Iowa State College.

Professor J. E. PETAVEL has been appointed director of the British National Physical Laboratory in succession to Sir Richard Glazebrook, retired. Professor Petavel is professor of engineering and director of the Whitworth Laboratory in the University of Manchester.

Mr. L. E. SAUNDERS, manager of research and abrasives plants, Norton Co., has been transferred to the main executive office at Worcester, Mass. Mr. P. G. SAVAGE becomes assistant to Mr. Saunders as resident manager of the plant at Niagara Falls, N. Y., and Chippawa, Ont., Canada.

Professor NORMAN A. SHEPARD, Yale University, New Haven, Conn., has resigned to enter the employ of the Firestone Tire & Rubber Co.

Mr. JEROME STRAUSS, formerly first lieutenant, Inspection Division, Ordnance Department, is now assistant chief chemist and metallurgist, U. S. Naval Gun Factory, Washington, D. C.

Current Market Reports

The Non-Ferrous Metal Market

Monday, Oct. 6.—Little activity is to be found in the non-ferrous metal market, but prices are firm and producers willing to carry stocks.

Aluminum:—The market remains quiet, small sales of 98-99 per cent ingots continue at 33c. per lb. Cast scrap is selling at 21¼-24½c.; sheet, 21-23½c.; clippings 23¼-27¼c.

Antimony:—Silver fluctuations are expected to have influence on the Asiatic markets. A spot lot of 50,000 lb. is reported sold at 8c.; small job lots bring 8 3/4c.

Copper:—No transactions of importance are reported in copper at the present price of 23 3/4c.

Lead:—There is a steady but small trade in lead at 6 1/4c. lb. in New York and 6c., East St. Louis. Sheet lead cuts are quoted at 9c. lb. Scrap lead, 5 1/2c. lb.

Tin:—London market is rising. Straits spots are quoted at 55 3/4c and electrolytic at 54 3/4c. lb. in New York.

Zinc:—Prices are advancing in East St. Louis. Spot New York is now 7.60c. and St. Louis, 7.25c. lb. Scrap zinc, 5 1/2c. lb.

The Iron and Steel Market

By reason of the strike, interest in the iron and steel market centers chiefly upon matters of requirements and supplies, for actual transactions are of small volume. The merchant furnaces are sold far ahead on pig iron, and the steel mills far ahead on finished steel products. Regular consumers are thus covered, subject to uncertainties of delivery on account of the strike, and have no particular occasion to make fresh purchases, while occasional or chance buyers cannot, as a rule, place orders.

The iron and steel strike began Monday, Sept. 22, and in three days had reached practically its height. Plants or districts that were largely affected at the outset went down completely, while those in which the strike did not get a good start succeeded in operating, and generally with gains in employment, so that after a few days more there was a clear cut division. Plants were either closed entirely or were operating practically normal. After the first few days the strike was spreading nowhere, but employment was spreading here and there, so that the strike was losing ground.

The gains in employment have been consolidated, and at the end of two weeks of strike the situation is that the East and South are operating practically full, western Pennsylvania is operating practically full, while Cleveland and the Mahoning Valley are down entirely, as is very nearly the whole of the Wheeling district. The next important development will be resumption in the closed regions. That may come soon or may be long deferred. The foregoing summary omits reference to some points or districts developments in which would not be crucial. Cambria at Johnstown, Lackawanna at Buffalo and Colorado Fuel & Iron at Pueblo are down entirely, while the Calumet district is operating at less than one-half and with great difficulty at that.

PIG IRON

Not because they are blast-furnaces, but because in large part they are more or less isolated, the merchant furnaces have been less affected by strike than the steel industry proper. Iron foundries are running as usual, while some steel works are not taking the merchant iron they usually take, and thus on the whole there seems to be an approximate balance whereby the strike does not make merchant pig iron either more plentiful or less plentiful.

STEEL PRODUCTS

The production of finished steel is at not more than about 60 per cent of normal. Even were the curtailment uniform in the various finished steel products, the influence as to producing a scarcity would not be uniform, because industries are in much more urgent need of some products than of others. A review will be undertaken as to supplies and requirements in a number of the finished products.

The case of plates stands by itself, for before the strike there was a large surplus of plate-rolling capacity, due to there being rather an eager demand while plate capacity had been increased very greatly during the war. The eastern Pennsylvania plate mills continued to run with scarcely any curtailment, but from Cambria at Johnstown and Lackawanna at

Buffalo westward there was almost complete closing of plate mills except for Homestead and a few small plants, even Jones & Laughlin being considerably affected. The result is that plates are now a trifle scarce.

At the other extreme is the case of oil country goods, involving practically the output of the lap weld departments of the pipe mills. The strike is geographical and it chances that four important independents, easily the bulk of the independent production, are closed, Republic and Youngstown Sheet & Tube at Youngstown, La Belle at Steubenville and Wheeling Steel & Iron in the Wheeling district. The National Tube Co., on the other hand, is but little affected. It lost its Riverside plant in the Wheeling district, of course, but little else. Its largest plant, McKeesport, ran fairly well, and its next largest, Lorain, was unaffected, although only a few miles from Cleveland, where everything went down. Of two smaller plants in Pittsburgh, Continental stayed in operation and Pennsylvania went down for a few days, afterward beginning to recover. Altogether, the production of pipe was curtailed by 50 per cent at the lowest estimate, yet before the strike there was an acute scarcity of oil country goods, so much so that many lessees in the Texas field were almost certain to lose their leases through being unable to drill wells within the time they had in judiciously set.

The strike was proposed as if it were to be primarily a strike against the United States Steel Corporation, yet it has just been indicated that in pipe the independents experienced more strike than the Steel Corporation. The same was true in the case of sheets, yet the divergence in each case is due chiefly to geography. The fact is, of course, that the agitators simply aimed to produce all the strike they could, their plans succeeding in some places and not in others. After ten days of the strike the American Sheet & Tin Plate Co. was operating 72 per cent of its sheet mills, while not more than 50 per cent of the independent sheet mills were operating. Of the Steel Corporation sheet plants, seven were operating in full. The Steel Corporation sheet plants chanced to be widely distributed, many being in towns where there were no other plants. The independent sheet industry is centered largely in the Mahoning Valley, which next to Wheeling is traditionally the worst strike district in the industry. Sheet mills making specialties were not closed in altogether as great proportion as mills making common sheets, and thus makers of automobiles, metal furniture, etc., are in line to be incommoded somewhat less than users of common sheets.

Much more than half of both the Steel Corporation and the independent tin plate mills were closed by the strike. While as a rule skilled workmen had little to do with the steel strike except through being thrown out of employment by the common labor striking, in the case of tin mills there was no small amount of striking by tonnage men. The curtailment in tin plate production is of very small moment when contrasted with conditions in other finished steel products, the canning season being over. In normal years tin plate production is lighter at this season than at any other in the year.

Production of plain wire and wire products is greatly curtailed in the case of both Steel Corporation and independents, but the fall distribution to jobbers had been completed, and the pressure for mill deliveries at this time of year is not heavy. Jobbers' stocks were relatively light. The mills operating, however, should keep the country moderately well supplied even should the strike in general be prolonged for several weeks.

PRICES

There are many steel producers who are prone to seize upon every argument that may be marshaled in favor of advancing prices. That is not so much because steel producers are always wanting to make more money as because it has been a sort of custom in past years to run the market by advancing prices and thus encourage buyers to make contracts. At the present time there is no talk of advancing prices, not simply because the market is not being discussed, but because it is recognized that it would be bad form in the circumstances. Producers note with interest Judge Cary's remark before the Senate committee investigating the steel strike that prices are high enough already and it would be better for prices generally to come down.

Chemists and Labor Unions

WE ARE informed that chemists and assistants on the staff of the Health Department of New York City have joined the Union of Technical Men, affiliated with the American Federation of Labor. With all appreciation of the American Federation of Labor and with due respect for the chemists and assistants on the staff of the New York Health Department, we think the latter should be ashamed of themselves. They occupy posts of grave responsibility, and they have turned over the ordering of their work to an irresponsible authority. If a strike should be called among them the health of over five million people would be put in jeopardy while the single problem of their pay or their hours or their recognition as a body was in process of settlement. Whether such an outrageous act is recorded as a crime on our statute books or not, the fact remains that such a strike would be criminal in the highest degree.

We hold no brief against labor unions or against collective bargaining for labor, either skilled or unskilled. But a professional man, in taking up his profession, assumes responsibilities beyond his daily wage. His education has cost either this or some other community more than he paid for it, and that is the least of his obligations to make good. In entering the service of the city he can stay as long as he likes and leave it whenever he can better himself. But for him to join a labor union and to use a labor union's medium of the strike, whereby a great community is threatened with infection and disease for the sole purpose of improving the conditions of his precious self, is getting things entirely out of focus. He isn't worth it and he should know it. And if he had the slightest sense of professional obligation he would know it.

The President's Industrial Conference

NO APOLOGY is necessary for devoting space in technical and engineering journals to the proceedings of the President's Industrial Conference at Washington. Not only are engineers and technical men everywhere in duty bound to inform themselves on industrial problems, but there is sufficient evidence that the daily press does not always reflect the proceedings of such a conference as an engineer would

see them. If reasons are needed, these are ample. Furthermore, the technical press has its share of the responsibility in keeping the thought of the country straight and sane on what is undoubtedly the most momentous problem before us today—satisfactory industrial relations.

The President's Industrial Conference is designed to be representative of the three parties in interest in industrial disputes, viz., Labor, Capital and the Public; or as they may be otherwise designated, Employees, Employers and the Public. It must be evident how difficult a task confronted the President in appointing such a conference, and probably his failure to select a thoroughly representative group was no greater than would have been experienced by anyone else essaying the task. But the fact remains that in the Conference Labor represents organized bodies only, and can by no stretch of the imagination be expected to express the concrete thought of the employees of the country. Labor is the only unified group in the Conference, but it is so because it comprises only members of unions. The Employers are more diverse in their interests, but here too there is lack of representation from many branches of industry. Finally, the Public is represented by a mixed group of Presidential appointees who come from many walks of life and are probably more representative of the people's thought than either of the other groups. Comment is openly made, however, that the Public Group has distinct sympathies toward Labor in its demand for more recognition of the worker and more equitable distribution of industrial production.

The first week of the Conference can scarcely inspire confidence in the hope that it will accomplish something constructive for the industrial life of the nation. Two things are evident: In the opinion of many, as expressed openly in the conference by Dr. ELIOT of the Public Group, Labor has not brought forward any distinctly new or progressive measures for consideration. Labor's proposals are those with which we have been familiar for many years, couched in the same old language and not fundamental in their scope. They are the same "demands" that have formed the basis of combat in years past, and can be designed only to strengthen the means of combat in the future. Second, the introduction of a resolution to have the Conference investigate and

settle the steel strike is generally regarded as ill advised and likely to prove a bone of contention that will threaten the usefulness of the Conference in devising a constructive program of industrial relations.

In our judgment the steel strike resolution should not have been introduced, because it is not germane to the purposes of the Conference and can only cause endless wrangling. Under the rules of the Conference there is not the slightest chance of a favorable vote on it, and an adverse vote may prove disastrous to further constructive work. Just what purpose Labor may have in bringing the matter forward at this time is not for us to say; but it is not difficult to surmise that the leaders seek thereby to divert public sympathy to the strike instead of from it, which latter is now the acknowledged trend. By offering to have the Conference adjudicate the strike, Labor can assume a magnanimous attitude before the country and can likewise play the role of martyr if the resolution is voted down, which it certainly will be if a vote is reached. On the other hand, should the Conference adopt the resolution, and should the strike be adjudicated in favor of the strikers, organized labor can find little for self-congratulation, because the strike is known to be the work of radicals within the labor movement, who would construe success as approval of their leadership. Nothing could be worse for Labor as a whole.

Control of Large Corporations And of Large Labor Unions

CONGRESS should give careful thought to the suggestion of Judge GARY, chairman of the Steel Corporation, before the Senate Committee on Education and Labor, investigating the iron and steel strike. Judge GARY expressed the opinion that concentrated capital should be under supervision and control of a Federal commission and that concentrated labor should be subjected to control of the Government and of the law.

This statement is carefully put. Is it saying something to assert that concentrated labor should be subject to the law? It is. Twenty-seven years ago Judge PAXSON, Chief Justice of the Supreme Court of Pennsylvania, selected, on account of the importance of the case, to charge the Grand Jury at Pittsburgh in the case against the Homestead strikers of 1892, said:

"It was not a cry for bread to feed their famished lips; the result of sudden outrage, with good provocation; it was a deliberate attempt of men without authority to control others in the enjoyment of their rights. The existence of such a state of things, in a government of law, indicates a weak spot somewhere. It is not in law itself. That is sufficient for the preservation of order; all that is needed is its proper enforcement."

Since Justice PAXSON delivered those words there has been no improvement, as shown by the wholesale

lawlessness in the iron and steel strike that began September 22. The lives of wives, mothers and children have been threatened, and there have been threats that homes would be burned in hundreds, possibly thousands, of cases, just for the purpose of keeping men from working. Mobs have marched from a striking plant to another that was operating and have gotten the men out, simply at the time the shifts changed. It seems to be a fair estimate that of the men employed in the iron and steel industry 10 per cent wanted in advance to strike; 20 per cent were inclined to strike when the time came, and 20 per cent were put out of employment by intimidation, making 40 per cent idle altogether. Some plants and some districts were closed entirely, others operated in full or in large part. The difference was made by two things, the difference in distribution of the men who wanted to strike, and the difference in the amount of protection afforded by the civil authorities.

Public sentiment has been largely responsible for this state of affairs. Justice PAXSON referred to that also, in his charge of 27 years ago. There is more sympathy for the man who wants to strike than for the man who wants to work. The morals of the public are very lax, and sympathy for the striker develops into a disposition to condone lawless acts.

There is a reason, however poor, for everything, and there is a reason for this state of the public mind. It is the notion that somehow or other the wage earner is at a disadvantage and is entitled to some extra consideration. Granting that such may be the case sometimes, it is equally possible for the wage earner to have an undue advantage. The pendulum may swing so far that injury will be caused everyone, for if men get too high wages and work too little they will eventually suffer and the public will certainly suffer through having to pay too much for goods, while capital may be destroyed. The public was given some very good food for thought in the Boston policemen's strike.

Why should it be difficult for us all to adopt the conception that the man and the job are equally important, that each has in essence what amounts to an undivided half interest in prosperity, that either is useless without the other?

There was fear at one time that large aggregations of capital were inimical to the public interest. Experience has shown that large corporations are amenable to public opinion, and indisposed to misuse the power they possess. Experience, and particularly recent experience, shows that large aggregations of workmen are disposed to misuse their power, to the extent of trampling on the law wherever they think it to their advantage. Whether the one requires control more than the other need not be debated. Let Congress simply decide that both must be controlled, and let it be made known universally, by whatever medium or means necessary, that the laws must be obeyed and that in a labor contest men have no license to disregard the law.

Readers' Views and Comments

H. R. Bills 5011, 5012 and 7010, 66th Congress,
First Session

To the Editor of Chemical & Metallurgical Engineering

SIR: The above bills in relation to patents were drawn by a carefully selected committee of the Research Council. They provide for a separate Patent Court of Appeals, to be established in Washington, consisting of a Chief Justice, appointed by the President for life, and six Assistant Justices, to be appointed for respective terms of six years, by the Chief Justice of the U. S. Court of Appeals, from among the U. S. Circuit Judges. By this means it is hoped to shorten patent litigation; an inventor or owner of a patent without unlimited capital may nevertheless secure his rights. Our present method of providing for this in nine U. S. circuit courts of appeal, of concurrent jurisdiction but limited territorial authority, makes this exceedingly difficult.

Another provision raises the salaries of the staff to a range commensurate with that provided for the staffs of other departments. This principal examiners are to receive \$4000 instead of \$2000, as at present; and various grades of assistant examiners are to be increased in proportion. The integrity and technical competence of these men, numbering several hundred, constitute the key to our patent organization. Every neglect, every error, in regard to important inventions, is fraught with heavy costs for litigation, which, in the end, the public must pay. Such defects also make for disorder and confusion. The entire increase, as I recall it, involves between \$900,000 and \$1,000,000 per year. I believe a considerable part of this would be defrayed by the fees taken in response to a better patent situation. Under present conditions, at the existing rates of pay, the Commissioner cannot maintain an adequate standard of technical capacity in his staff.

Another provision authorizes the court to determine upon a reasonable royalty in the case of infringement. It is very rare that the owner of a patent can give the exact measure of the damages incurred through infringement by his opponent, inasmuch as a single patent seldom covers the whole of an article which is made and sold under infringement. The usual award in such cases is six cents to a successful contestant for his patent rights where these are proved.

Still another provision removes the Bureau from the jurisdiction of the Secretary of the Interior, and makes it a separate bureau. Under existing conditions the Honorable Secretary of the Interior has in substance no authority over the Bureau to make changes in organization or procedure, although his approval is required for these.

I respectfully urge on your favorable consideration the bills above mentioned.

E. P. O.

New York City.

The Design of Electric Furnaces

To the Editor of Chemical & Metallurgical Engineering

SIR: In your issue of Sept. 1 you have an article by R. C. Gosrow entitled "The Design of Electric Furnaces." Mr. Gosrow in his article refers to an article of mine originally appearing in the Transactions of the A.I.M.E. which you abstracted. In looking over Mr. Gosrow's article I find on page 238 tabulated details with reference to a certain furnace. It is there stated that with a 1650 kw. input his furnace produced 16 tons of 81.5 per cent ferromanganese daily from ores of which he gives an analysis.

I wish to call your attention to the fact that this is an impossibility. Were it true it would mean that the furnace produced ferromanganese for something like 2360 kw-hr. per ton. The lowest figure that I have ever seen is 4000 kw-hr. per ton of metal, and this is open to some question. I have been interested in figuring the theoretical power consumption in the case of this furnace and find that it would require about 6500 kw-hr. per ton. Is the 16 tons a misprint?

E. S. BARDWELL.

Great Falls, Mont.

To the Editor of Chemical & Metallurgical Engineering

SIR: Mr. E. S. Bardwell's comment on my article in the Sept. 1 issue of CHEMICAL & METALLURGICAL ENGINEERING is not without justification. My original figures were compiled from furnace reports and data. The tonnages of alloy and the consumption of energy show an average kilowatt-hour consumption per ton of alloy of 2860. The figures as given in my report and article are correct for furnace load, and the error undoubtedly occurred through transposing the reports into the figures for this article. This then shows an average tonnage for the period of 13½ net tons, which is what the average from the actual tonnages shows.

I do not doubt Mr. Bardwell's statement that 4000 kw-hr. is open to question when other reducing agents are used than charcoal or coke, and running an excessively hot top furnace.

I cannot check Mr. Bardwell's figures for theoretical power consumption at about 6500 kw-hr. for this furnace.

R. C. GOSROW.

Seattle, Wash.

The American Academy of Arts and Sciences has voted an appropriation of \$300 to Professor Frances G. Wick of Vassar College to aid her in research on the phosphorescence of hexagonite and of fluorite at ordinary and low temperatures, and to Dr. R. W. Wood, professor of experimental physics at Johns Hopkins, \$350 in addition to former appropriations for continuation of optical investigations.

Six thousand dollars has been given to Columbia University for special research in food chemistry.

Western Chemical and Metallurgical Field

Northwest Magnesite Co.

The company quarries from a large deposit of crystalline magnesite near the town of Chewelah, in Stevens County, Washington, about 60 miles north of Spokane. The mineral occurs as a replacement of lenses of dolomite in sedimentary rocks, in which are found dolomite, shale and quartzite, and into which basic igneous rocks have been intruded. A large portion of the deposit has been diamond-drilled to a depth of 300 ft. By this means data have been obtained for classifying the deposit in sections, depending upon lime and silica content. About a million tons of high-grade mineral has been explored by drilling. Owing to the thickness of the high-grade deposits, it is unnecessary to employ manual methods for selecting ore during or after mining.

At the present time, the bulk of the mineral is being taken from an open quarry near the top of a ridge known as Finch Quarry, whence it is lowered by an

FINCH QUARRY

aërial tramway to a crushing plant near the foot of the ridge. The crushing plant consists of a large jaw crusher which takes the mineral as quarried and delivers it to one of a set of two gyratory crushers, which reduce it to 2-in. size and deliver it to the storage bins at the tramway head. From these bins the mineral is transported by an aërial tramway five miles in length and delivered into the crushed mineral storage bins at the calcining plant. The storage bins have a capacity of 800 tons, which is sufficient to supply the plant 24 hours. The entire operation of quarrying, crushing and transporting being mechanical, the crushed mineral is delivered to the storage bins at the calcining plant at a minimum cost.

The first operation at the calcining plant is a further reduction of the mineral by means of a set of rolls; this final product will all pass through a 10-mesh and about 20 per cent will pass through a 100-mesh screen. The proportion of the fine material in the crushed mineral is important, as it assists materially in producing a uniform product as a result of the reaction between the iron oxide and the magnesite in the rotary kiln. The crushed mineral is weighed in 1-ton batches and to each

AERIAL TRAMWAY

batch is added about 40 lb. of finely pulverized high-grade magnetite (iron oxide). The weighed materials are delivered to, and thoroughly incorporated by, a rotary mixer, from which the product is delivered by means of an elevator and conveyor to storage bins at the head of the rotary kilns.

The rotary kilns, of which five are installed, are 125 ft. in length, 7 ft. 6 in. in diameter; they are lined throughout with 9-in. No. 1 fire clay brick. Powdered coal of a sub-bituminous type obtained from a nearby mine is used for fuel, being supplied to the kiln by a Bonnet pulverized-coal-system of 150 tons daily capacity. About 700 lb. of coal containing 12,000 B.t.u. per lb. is required to produce one ton of ferromagnesite. Each kiln has a maximum capacity of 70 tons of dead-burned magnesite per day. About 2.2 tons of raw material is

CALCINING PLANT

required per ton of finished product. The incandescent ferromagnesite emerging from the kilns is cooled by passing through revolving air-cooled steel tubes; it is then crushed by rolls and sorted by screens into sizes required by the trade. The ferromagnesite building has storage capacity for 1000 tons of finished product and is located on a spur track, loading being direct into cars. The process of manufacture from the crushed ore storage bins to the finished product storage is continuous.

President's Industrial Conference Meets in Washington

Three Groups, Representing Labor, the Public and Employers, Convene to Reach, if Possible, Some Common Ground of Agreement and Action With Regard to the Future Conduct of Industry—Resolutions Presented by the Groups

THE Industrial Conference called some weeks ago by the President "for the purpose of reaching, if possible, some common ground of agreement and action with regard to the future conduct of industry" convened in Washington at the Pan American Union Building, Monday afternoon, Oct. 6. Owing to the illness of the President the Conference was called to order by Secretary of Labor Wilson, who acknowledged the courtesy of the Pan American Union in granting the use of the building for this occasion, and called upon John Barrett, Director General of the Pan American Union, for a brief address. Mr. Barrett's remarks were particularly appropriate, and calculated to throw an atmosphere of peace and harmony about the proceedings. Speaking of the Union as a practical league of 21 American nations, Mr. Barrett said that the deliberations of its board of governors had been the means of averting at least six potential wars among the member nations, while no conflict of any importance had occurred since the Union was established. Dedicated to the purposes of peace, the Union hoped that the Industrial Conference might be successful in finding a just and fair solution to its problems amid surroundings where many political issues had been amicably settled.

LABOR, THE PUBLIC AND EMPLOYERS REPRESENTED

The official delegates to the Conference comprised three groups, representing Labor, the Public and Employers. Labor delegates were seated on the left, Employers on the right, with representatives of the Public in the middle. Over 75 representatives of the daily and industrial press were present to report the proceedings.

After the President's official call was read there was a roll call of delegates representing respectively:

The Public: Bernard M. Baruch, Robert S. Brookings, John D. Rockefeller, Jr., Elbert H. Gary, Charles W. Eliot, John Spargo, O. E. Bradfute, Ward M. Burgess, Fuller E. Calloway, Thomas L. Chadbourne, H. B. Endicott, Paul L. Feiss, Henry S. Dennison, George R. James, Thomas D. Jones, A. A. Landon, E. T. Meredith, Gavin McNab, L. D. Sweet, Louis Titus, Charles Edward Russell, Bert M. Jewell.

Women: Lillian D. Wald, Gertrude Barnum, Ida M. Tarbell.

Chamber of Commerce of the U. S.: Harry A. Wheeler, Ernest T. Trigg, Herbert F. Perkins, John J. Raskob, Homer L. Ferguson.

Farmers' Organizations: J. N. Tittmore, T. C. Atkeson, C. S. Barrett.

Investment Bankers Association of America: Edgar L. Marston, Howard W. Fenton.

Organized Labor: Samuel Gompers, Frank Morrison, Daniel J. Tobin, Joseph F. Valentine, Frank Duffy, W. D. Mahon, T. A. Rickert, Jacob Fischer, Matthew Woll, John L. Lewis, Mrs. Sarah Conboy, William H. Johnston, Paul Scharrenberg, John H. Donlin, M. F. Tighe.

National Industrial Conference Board: Frederick P. Fish, J. W. O'Leary, S. Pemberton Hutchinson, Edwin Farnham Green, Leonor Fresnel Loree.

Railroad Brotherhoods: Engineers, H. E. Wills; Fireman, P. J. McNamara; Trainmen, W. G. Lee; Conductors, L. O. Sheppard.

Railroad Managers: R. H. Aishton, Carl R. Gray.

PURPOSES OF CONFERENCE EXPLAINED BY SECRETARY WILSON

Secretary Wilson then delivered a short address on the purposes of the Conference. First expressing regret that the President was unable to direct the Conference in person, the Secretary reviewed briefly the industrial conditions that had grown out of the war. The loss of life, the destruction of material resources, the derangement of industry, and the instability of governments have all contributed to the most difficult peace-time problem that has ever confronted the country.

"The effect of these things," he said, "has been reflected in the high cost of living and the consequent demand for higher wage rates to meet the increasing burden of the family budget. Yet increases in the wage rate do not always give relief. There are but two ways by which the general standard of living of the wage-workers can be improved. One is by increased productivity, making more material available for wages. The other is by taking the means of increased compensation out of the profits of the employer. If wages are increased and profits remain the same, the burden is passed on to the consuming public in the form of an increased cost of living, and comes back in that form to the wage-worker himself. No portion of improved standards of living can come out of the profits of the employers unless there is profiteering.

WHOLE WORLD INTERESTED IN PRODUCTION

"The whole world is interested in returning to the highest productive efficiency, having due regard to the health, safety, and opportunities for rest, recreation and improvement of those who toil. The most productive we are the sooner we will replace the wastage of war, return to normal price-levels, and abolish the opportunity for profiteering. There can be no profiteering where the production is ample to meet the needs of the people of the world if there is a free flow of

material from producer to consumer. It is only where the production is not sufficient for the needs of the people, or, when sufficient, where artificial obstructions impede proper distribution that there is any possibility of profiteering. Anything that restricts the highest efficiency commensurate with the physical, mental and spiritual well-being of the workers tends to retard the progress of the country as a whole.

INDUSTRIAL JUSTICE THE BASIS OF INDUSTRIAL PEACE

"For that reason we are all interested in the maintenance of industrial peace, but there can be no permanent industrial peace that is not based upon industrial justice. Nor is it sufficient that either side to an industrial controversy should be the sole judge of what constitutes justice. The means must exist by which all men may know that justice has been secured. An imaginary wrong has all the force and effect of reality until it is shown that it is only imaginary. We have found ways of regulating all the other relations of mankind. Surely human intelligence can devise some acceptable method of adjusting the relationship between employer and employee.

"The right of any man to cease working for another for any reason that is sufficient to himself is the basic element of human liberty. The right of any person to refuse to operate his plant at any time he desires to do so is the exercise of a property right guaranteed by the Constitution. It does not follow that because these rights exist it is necessary to exercise them. They must nevertheless be safeguarded. Having done that and having devised the machinery by which justice can be secured and by which everybody at interest has the opportunity of knowing that justice has been secured, it is not likely that the right to cease work will be exercised by sufficient numbers, or the right to cease operating industrial plants will be carried to such an extent as to seriously affect the welfare of the balance of the people."

COMMITTEES APPOINTED

Following the Secretary's address, which was well received, he announced that the Conference would perfect its own organization and method of procedure. At his suggestion each of the three groups of delegates appointed two committees of three each, to constitute general committees (1) on organization and nominations and (2) on rules and order of business. The appointees were as follows:

On organization and nominations: Labor—Messrs. Morrison, Tobin and Sheppard. Employers—Messrs. Perkins, O'Leary and Marston. The Public—Messrs. Landon, Meredith and Brookings.

On rules and order of business: Labor—Messrs. Mahon, Woll and Lee. Employers—Messrs. Green, Wheeler and Atkeson. The Public—Messrs. Baruch, Chadbourne and Rockefeller.

The Conference then adjourned until Tuesday morning, Oct. 7, and the committees met immediately thereafter for the transaction of business.

When the Conference again convened a permanent organization was effected with the Hon. Franklin K. Lane, Secretary of the Interior, as chairman, and J. J. Cotter and Lathrop Brown as secretaries. The selection of Mr. Lane as chairman was regarded by all as particularly happy on account of his recognized interest in the purposes of the Conference, his record for fairness and his private and public integrity. In his speech of acceptance Mr. Lane expressed confidence in the possibility of finding a solution for the problems to be considered. He approved of the Conference, which he said is the most important extra-legal body organized within our time. He also scouted the idea that social revolution would be necessary to accomplish the reforms in this country which have been sought by violent means in Russia and elsewhere, because, he said, our democracy had been achieved by a revolution that established our principle of government once for all. He considered the qualities of ignorance and arrogance to be the causes of unrest and dissatisfaction, and said that by the exercise of intelligence and tolerance we could be assured of some degree of success.

The committee on rules and order of business made its report, submitting a scheme of which the following were the salient points: Organization by groups for the consideration within the groups of any matters which members of the Conference may wish to bring before the entire body; assent required by each group before any proposal could be submitted to the Conference; a general committee of 15, five from each of the three groups, to which shall be submitted all proposals emanating from the groups; report by the general committee to the Conference, with or without recommendations; provision for minority reports; limitation of debate to 10 minutes; public sessions.

The General Committee was then constituted by group action, as follows:

Employers—Messrs. Hutchinson, O'Leary, Perkins, Raskob (secretary), Tittamore.

Employees—Messrs. Gompers, Morrison (secretary), Woll, Sheppard, Mahon.

The Public—Messrs. Chadbourne (chairman), Endicott, Landon, Russell, Miss Wald.

RULES OF PROCEDURE

When the Conference convened Wednesday morning, it was merely to announce the organization of the General Committee and a few additional rules of procedure. According to the rules adopted by the Conference, all proposals and programs must originate in one of the three groups, be referred automatically to the General Committee of 15 if assented to by the group, and then referred back to the Conference, with or without amendment, for debate. Under these conditions the Conference found itself on the third day of its convention without anything to do, but with approved machinery for doing anything that might be brought up. There was nothing to be done, therefore, but to adjourn the Conference until Thursday morn-

ing so that the groups might discuss proposals of their respective members and agree, if possible, on resolutions or programs for presentation to the General Committee.

When Secretary Lane adjourned the meeting for the day he wisely suggested that the delegates remain in the room for half an hour or more and get acquainted with each other. He thought the purposes of the Conference would be advanced if the representatives of the three groups knew one another personally.

RESOLUTIONS AND PROPOSALS PRESENTED

Following the rules, certain resolutions and proposals were offered by the three groups, representing Labor, the Public and the Employers; and while it is certain that other resolutions will be presented next week, and for that matter throughout the early weeks of the Conference, it may be worth while to examine those already offered and study their points of agreement and divergence.

The Public Group was the first to offer resolutions, and these were presented in the names of their respective authors with the "assent" of the group to their consideration by the Conference. This was strictly in accord with the agreed procedure, and it was made clear that the group did not necessarily approve of the proposals, but merely assented to their presentation as germane to the objects of the Conference.

Labor, on the other hand, when its turn came to offer proposals, brought forward a program in which the group concurred as a whole, thus presenting a united front. Mr. Gompers made it plain that the Labor group had acted as a body in formulating its program, and that there was "no pride of authorship" in any of the proposals. On the contrary, Labor had endeavored to enunciate a series of "principles and actions which they believed would contribute most to the purpose of the Conference as indicated in the President's letter." In this the four railroad Brotherhoods concurred, although doubt had been expressed as to whether they would ever enter the Conference.

When the Employers Group was called upon for its resolutions nothing was offered because of lack of time in which to formulate a program to which all would assent. Unlike the Labor Group, which represented a single element, strongly organized and united, the Employers were composed of delegates from widely separated industries, and more time was required to enunciate a set of principles. Later, however, the Employers brought forward one resolution by Mr. Loree and a "statement of principles which should govern the employment relation in industry." Both of these documents were of the highest importance, and the latter was especially broad, comprehensive and progressive.

During the discussion which ensued on the request of the Employers Group for more time, Dr. Eliot took occasion to comment on the purposes of the Conference and on the nature of the resolutions offered by

Labor. Arguing that the Conference was called for the purpose of discovering *new* relations between capital and labor, he contended that the program offered by Labor was along old lines and contained only the old familiar contentions that had been the subject of endless dispute. "The fact is," he said, "that the speech just made by Mr. Gompers shows that Labor is here to contend within the Conference for what are called the rights of labor; and there have occurred many indications already that there is a large group of employers who are prepared to resist the methods of approach to business which we have heard proposed by the group of Labor. Among all the propositions that have been submitted to this Conference this morning there are several which relate, not to new relations between capital and labor, but to the old, to the former conditions of things in this country, in regard to industrial strikes, to the strengthening of the modes of combat with which our whole community has now become familiar. I venture to suggest that the Conference ought to make a new start if it is going to bring to pass any substantial results in creating new relations between capital and labor."

DISPOSAL OF RESOLUTIONS ORIGINATING OUTSIDE OF THE CONFERENCE

After the three groups had introduced their resolutions, Chairman Lane announced that numerous suggestions bearing on the work of the Conference had been received by him, and he asked what disposal should be made of them. This precipitated a debate in which the attitude of Mr. Gompers was misunderstood as being opposed to receiving outside suggestions. In his remarks on the subject he departed from the question long enough to pay his respects to the manner in which the Conference proceedings were being reported in the daily press, scoring particularly the inaccurate and unfair stories appearing in the *Washington Post*.

On the suggestion of Secretary of Labor Wilson, the Conference finally agreed to receive all suggestions offered from whatever source, prepare them in triplicate and submit them to the three groups of the Conference for consideration.

LABOR ASKS SETTLEMENT OF STEEL STRIKE

The first resolution introduced by the Labor Group was one calling upon the Conference to appoint two of its members from each group to constitute a committee to adjudicate and settle the differences between the workers and employers in the steel industry. There was a wide difference of opinion on the propriety of bringing this matter before the Conference, many feeling that the Conference was not called to settle individual disputes but to devise means for effecting settlements and if possible avoiding strikes and lockouts. There was ample evidence that the resolution might become the most contentious matter before the Conference and considerable doubt was expressed as to its adoption.

In addition to this resolution Labor presented a

platform of principles declaring for collective bargaining; the eight-hour day; minimum living wage; equal pay for women performing equal work with men; prohibition of child labor; the establishment of industrial labor boards for conciliation and arbitration; and prohibition of immigration for a period of two years following the declaration of peace.

Similarly the Employers Group offered a set of principles on the following topics: Production; the establishment rather than the industry as a productive unit; conditions of work; wages; hours of work; settlement of disputes; right to associate; responsibility of associations; freedom of contract; the open shop; the right to strike or lock out; training.

CONFERENCE TO ACT IN INTEREST OF GENERAL PUBLIC

The first of the general resolutions to be introduced was that of Mr. F. P. Fish of the Employers Group, designed to commit the Conference to the principle of acting for the whole people—the consuming public—rather than in the interest of any one of the three groups represented in the Conference. The resolution declared that “the questions to be considered by this Conference are of vital importance to all the people of the United States individually and connectively”; that each and every citizen is interested in securing the benefits that would flow from harmonious relations between capital and labor; and that it is the duty of each delegate to feel that he is a representative of all the the people.

RESOLUTIONS ON COLLECTIVE BARGAINING

The other resolutions introduced during the first week of the Conference covered a wide range of subjects, but can be classified under a few headings. Collective bargaining came in for more attention than any other subject, being the basis of five resolutions. Mr. Dennison of the Public Group offered one suggesting that “employers and employees in every factory should unite in bringing about the development of committees freely elected by the employees (whether as a part of the trade union system or otherwise but not in antagonism to trade unionism) for the joint consideration of such constructive matters as methods of enlisting workers' interest and of improving efficiency of production, which are of mutual value to employers and employees.” Another resolution of Mr. Dennison seeks to provide for equality of bargaining power by having (1) employers recognize the right of their employees independently to organize for the purpose of collective bargaining and to be ready to meet “any group of their employees either directly or through representatives”; and (2) labor recognize the right of employers to deal with their employees directly, “through freely elected shop committees or otherwise, as well as through trade unions.”

The views of the Labor Group on this important subject were embodied in a part of their propositions. They declared in favor of “the right of wage-earners to organize in trade and labor unions for the protection and promotion of their rights, interests and wel-

fare; the right of wage-earners to bargain collectively through trade and labor unions with employers regarding wages, hours of labor, and relations and conditions of employment; the right of wage-earners to be represented by representatives of their own choosing in negotiation and adjustments with employers with respect to wages, etc.” Labor further declared for the “right of employers to organize into associations or groups to bargain collectively through their chosen representatives with respect to wages, etc.”

Mr. Rockefeller's resolution on collective bargaining affirmed that inasmuch as the only common ground for agreement in industrial relations must be “the spirit of justice, brotherhood and willingness to put one's self in the other man's place,” employees must have representation in industry which will give them an effective voice in determining their terms of employment and their working and living conditions. He believes that the particular form of representation is a question to be decided in each case, but that “adequate representation” shall include provision whereby stockholders and employees' representatives may give current consideration to matters of common interest. He also states that provision should be made “to insure the prompt uncovering of grievances, real or alleged, and their speedy adjustment.”

On this same subject the Employers Group made the following declarations: “Each establishment should develop contact and full opportunity for interchange of view between management and men, through individual or collective dealing or a combination of both, or by some other effective method”; and further that “each establishment should provide adequate means for the discussion of all questions and the just and prompt settlement of all disputes that arise between management and men.”

MEDIATION, CONCILIATION AND ARBITRATION

Related to the resolutions on collective bargaining, and of no less importance, were those on methods of conciliating the parties to industrial disputes and arbitrating their differences. These proposals embodied specific plans, and it is not unlikely that they will comprise the most important subject to be considered by the Conference.

Mr. McNab of the Public Group offered a resolution based on the premise that it is “the purpose of this conference to discover a method of removing the causes of industrial unrest and strife.” He proposed legislation by Congress to create a National Board of Conciliation and Arbitration constituted as follows: Four members, at least one of whom shall be a woman, to be appointed by the President; two members to be appointed by the Senate and two by the House of Representatives; and the remainder to consist of the ex-Presidents of the United States and the Secretary of Labor. This board would be available for the settlement of all disputes between capital and labor, acting either as a board or through one of its members being a third party to a joint board of contending

parties. A condition of arbitration by such board would be the resumption of normal relations during the hearing, and the findings would be retroactive to the date of the controversy.

Secretary Wilson's plan calls for the creation of boards of employers and employees in each principal industry and a similar board for miscellaneous industries. Representatives on these boards are to be selected as the employers and employees may respectively determine. Industrial disputes that cannot be adjusted locally are to be referred to the board created for that industry, the board to take jurisdiction whenever in the judgment of one-half of its members a strike or lockout is imminent. If the particular industrial board cannot adjudicate the matter it is to be referred to a general board to be appointed by the President as follows: One-third to be appointed in agreement with organizations representative of employers, one-third in agreement with organizations representative of labor, and one-third by the President direct. This general board must be unanimous in its decision on disputes submitted to it, and in event of failure to reach unanimity the question shall be submitted to an umpire selected by unanimous action of the general board or drawn by lot from a list of 20 persons named by the President to act as such umpires. Decisions, however reached, are to have the force and effect of trade agreements which both sides shall be morally bound to accept and abide by.

The Labor Group's proposal on this subject called for the establishment in each industry of a national conference board, "by agreement between the organized workers and associated employers, consisting of an equal number of representatives of workers and employers." This industrial board should consider subjects affecting the progress and welfare of the industry, promote efficiency of production and the rights of all concerned. Further, the Federal Government should be asked to act through the Department of Labor in encouraging the formation of industrial conference boards in the industries where they do not now exist.

RESOLUTIONS ON IMMIGRATION AND MISCELLANEOUS SUBJECTS

Other important proposals touched on such subjects as the high cost of living, hours of labor, wages, the employment of women and children, and immigration. Labor stood fast for the standard eight-hour day, while the Employers declared that hours "should be fixed at the point consistent with the health of the worker and his right to an adequate period of leisure for rest, recreation, home-life and self-development. The standard of the work schedule should be the week, varying as the peculiar requirements of the individual industries may demand." Both sides agreed on the necessity of one day of rest in seven; the payment of overtime at the rate of time and a half was mentioned by Labor.

On the subject of wages Labor demanded "a living wage which shall insure the workers and their families to live in health and comfort in accord with the concepts and standards of American life." The Employers, on the other hand, suggested that the determination of wages must take account of the efficiency of the worker, recognizing "the quantity and quality of his productive effort." They agreed to a minimum wage that should enable the worker to maintain himself and family at a standard of living satisfactory to a right-minded man in view of the prevailing cost of living. Bonus payments, profit-sharing and stock ownership were recommended for consideration. Equal pay for women doing the same work as men was approved by both sides.

Immigration was dealt with only by Labor, which asked that all immigration into the United States be prohibited at least until two years after the declaration of peace. It was further declared that the flow of immigration should at no time exceed the nation's ability to assimilate and Americanize the immigrants, and that immigration should always be prohibited when an abnormal condition of unemployment exists in the United States.

An effective method of dealing with the high cost of living was sought in a resolution by Mr. Russell of the Public Group calling upon Congress to pass an anti-profiteering act similar to that of Great Britain.

The shortest resolution offered was that of Mr. Fuller Calloway of the Employers, as follows: "Resolved that individual initiative and enterprise should be encouraged." Despite its brevity this resolution embodies a principle which is a matter of contention between workers and employers. It has been claimed that labor organizations tend too much toward standardization of the job and the individual and the output, without providing for or recognizing the necessity of offering incentives for greater effort or superior ability on the part of individuals. After offering his resolution Mr. Calloway spoke at some length on the system adopted in a cotton-mill community at La Grange, Ga., where various co-operative schemes have been in vogue between the employer and employees, including provision for education, health and hygiene, and recreation, as well as a scheme for profit-sharing.

REQUEST FOR CENSUS DATA

Of fundamental importance was a resolution by Mr. Loree of the Employers asking that Congress take necessary steps to secure information on our population, employed and unemployed, male and female; home and foreign income; wages, hours of labor, salaries and profits of the principal industries; surplus and depreciation; taxes, royalties, rents, interest, advertising; reserves necessary for the progress of an increasing population and the spendable income of management and capital. It was urged that full advantage be taken of the census of 1920 in securing much of this information.

The Employers' program was more comprehensive than that of the Labor Group and was considered also by many to be more progressive. It naturally gave more attention to the function of Management in industry than did the Labor program, for Labor regards Management as a side partner with Capital and not as an intermediary responsible to both Capital and Labor. The Employers also preferred to consider the individual establishment rather than the industry as the unit in which industrial relations should be fostered and improved. Where Labor contends for the unionization of an entire industry and the settlement of wages, hours of labor and conditions of employment throughout that industry, the Employers suggest that better results can be obtained by experimenting in the establishment. On the subject of wages, Labor wants all of the workers' reward to be paid as wages and not as additional compensation in the form of profit-sharing, bonuses and stock ownership.

On the subject of the open or closed shop the Labor Group made no proposition, but the Employers declared for the open shop "in which membership or non-membership in any association is not made a condition of employment." They also declared that "coercive methods aimed at turning the 'open shop' into a 'closed union' or 'closed non-union' shop should not be tolerated."

On the subject of strikes and lockouts the Employers again made a declaration without a corresponding one from the Labor Group being offered. The Employers distinguished sharply between employment in the field of private industry, in public service and in Government service. The nature of Government service and that of the utility corporations was regarded as sufficiently different from that of private industry to warrant the prohibition of strikes on the part of workers engaged in such work. "A strike of Government employees is an attempt to prevent the operation of government until the demands of such employees are granted, and cannot be tolerated." On the other hand, "the right of Government employees to be heard and to secure just redress should be amply safeguarded." The sympathetic strike was condemned, as was the blacklist, the boycott and the sympathetic lockout.

LABOR SEEKS ACTION ON STEEL STRIKE RESOLUTION

Adjournment of the Conference at the end of the first week of its deliberations came in a rather dramatic way and showed clearly that there was a deadlock, temporarily at least, on the issue of attempting to settle the steel strike. Various members of the Conference had previously addressed themselves to the proposition that the resolution was not germane to the purposes of the Conference, and stated that it should not be considered. The Committee of Fifteen, however, had to consider it, under the rules, and report it in some way or other to the Conference. The chairman of this committee reported on Friday after-

noon, Oct. 10, that the steel strike resolution had occupied the attention of the committee for some hours and that no report of substance or merit could be expected without further work. An adjournment was moved until the following Tuesday morning. Mr. Gompers, however, was loath to see the resolution go over till the next week, and suggested a shorter adjournment, which was finally agreed to. It was quite evident that Labor was banking heavily on the action of the Conference on this resolution and wanted early action. Adjournment for one hour was then agreed to, but at the end of that time the General Committee reported in favor of adjournment until Tuesday, as in the first instance. It was apparent from this action, without further announcement, that the committee had been unable to agree on a report on the resolution to settle the steel strike, and the Conference was adjourned.

American Petroleum Institute

Plans whereby the American Petroleum Institute will spend at least \$500,000 annually for research and statistical work practically have been completed. The proposed organization of the Division of Research and Statistics submitted by Dr. Van H. Manning, the director of the Bureau of Mines, has been approved and will be put into effect in the near future, it is understood.

The division is to be under the general supervision of a technical director. His chief assistants are to be an economist and an engineer. The economist, in addition to studying the economic phases of the industry, is to have charge of statistics. The engineer will be in charge of research. It is the intention to concentrate in the Institute all statistics regarding individual operations from which generalized statements can be made to the Government or for publication. The statistics will go deeply into the matter of prices of crude oil, refined products and natural gas. Economic studies are not to be confined to the United States but will extend to foreign countries. So that work may be thorough, agents will be located in important foreign commercial centers. Steps will be taken to bring about uniform cost accounting and uniform laws and regulations.

Under research the division will take up studies of production, chemical engineering, utilization, and work on special problems. In the matter of chemistry it is admitted that an almost unlimited field is presented, but at the start the work will be concentrated largely on the selection and correlating of chemical information pertaining to oil and natural gas. Among the problems which are to receive early attention are: Recovery of spent acid in refining gasoline and kerosene; development of more efficient distillation methods for very closely refined products and a more efficient recovery of uncondensed gases from the stills. Cracking processes also are to be studied with regard to chemical engineering and general economy.

The Dangers of the Postal-Zone Law

BY ARTHUR CAPPER
U. S. Senator from Kansas

THERE is no subject of greater importance to the public than that involved in the postal principles on which is based our postal legislation. The present postal-zone law needs careful consideration, and every citizen and home throughout this nation should earnestly endeavor to understand the important factors involved.

For there is no function of government that reaches every citizen and every home to the extent of our United States postal service. For over seventy years the history of our postal legislation shows that our country has not legislated for postal service on the basis of cost, because the postal service is of such universal benefit, is such an instrument of information and education and unification, that to restrict it in any way is to hurt the country that we as thinking citizens wish to serve. So clearly and firmly has this American postal principle been held, that postage cost must not determine the postage rate, that our post office has delivered letters and publications to Yankee whaling ships at Point Barrow in the Arctic Circle for two cents that cost over \$5.60 to deliver. I would ask any thinking citizen if it is not just as important that a Yankee skipper home from a whaling cruise shall be able to understand and vote intelligently upon the great public questions of the day as it is for the citizen who has stayed at home? This principle is sound. Shall not California, Kansas and Maine have equal postage on all information as an American right?

Our rural free delivery system—the most expensive and least revenue-producing branch of the post office—costs 1½ cents per piece of mail matter, and this 1½ cents is over and above the cost of collecting, sorting, handling, transporting and rehandling until it gets into the rural free delivery carrier's wagon. This has all been done upon the American postal theory that the post office function was a service to the American people and that the cheapness of postage was a benefit to the American home.

It has been alleged—and maybe some have fallen victim to its un-American and illogical absurdity—that cheap postage on magazines and newspapers is a subsidy to the publishers. It is not a subsidy to the publishers. It is, if you want to use the term "subsidy," a subsidy to American readers. You can determine this for yourself. Who receives the benefit or subsidy when the Yankee skipper of a whaling ship off Point Barrow, in the Arctic Circle, receives news from home which costs \$5.60 to deliver? Is that a subsidy to his home newspaper, his periodical or magazine, or is the benefit of that to the ship captain himself and his citizenship and our united and national standards of intelligence?

You will instantly recognize that it is this ship captain receiver of costly postal service who is benefited, and your common sense will instantly prove to you that in every case of cheap postage the primary and entire benefit is to the receiver. Would you have Kansas pay higher postage than New York merely because any information happened to be printed in New York? Why handicap the postal service of Kansas by a higher and discriminatory postage rate? I come from Kansas, but the discrimination is similarly true of every other State.

Cheap postage on periodicals and newspapers has

made the American nation a nation of readers beyond any nation in the world. If there is any thought in your mind that *this is not* a national benefit, I ask you to compare in your mind this great country with its splendid and homogeneous American idealism, its singleness of purpose and the universality of its achievements with those nations in the world in which there is but little magazine reading.

Now as a practical proposition. You know the economic law that all costs must ultimately be paid by the final consumer, i.e., in this case the reader. To raise the postage on publications means that the publishers, as business men, must add this charge to the price of their periodicals—and thus lessen reading. Is this a good thing? And again I ask every reader to consider those nations in the world which have never encouraged widespread reading nor the widespread distribution of periodicals and newspapers, and to answer that question.

This country had a postal-zone system at one time, applying to letters and newspapers and periodicals. The abolition of the zone system was made complete by President Lincoln in 1863 and the zone system was abolished not only on periodicals and newspapers, but also on letters, because it was regarded as an unsound postal policy and un-American that a citizen or home should have to pay more postage simply by an accidentally greater distance from the point of mailing.

Now on the practical side I wish to point out that the country newspapers have circulation in their county of publication without any postage charge whatsoever and this can only be justified and continued on our American theory that the postal function is an equal service to all American homes.

It would be obviously unfair for those supporting the postal theory that the cost must determine the rate of postage to ask that a letter costing 1½ cents for delivery alone on rural routes should be sent for one cent. I do not have to be convinced that we should have one cent letter postage. I am for cheap postage as a great American social service. I believe that every right-thinking American is for cheap and equal postage. But there is no logical reason for believing that the rate on one class of postal matter must be determined by the rate on another class of postal matter. The figures of postal cost upon which this unsound and un-American postal cost theory is demanded were compiled in 1907 and upon being investigated by the United States Postal Commission headed by the Hon. Charles E. Hughes, these figures were discarded as utterly unreliable in determining the cost of handling newspapers and periodicals. Yet it is upon these discarded cost figures that such unsound arguments are based.

If we must abolish postal service—or increase postage rates to a prohibitive basis—on the theory that cost of service shall determine the postage rates, we should have to abandon many of the most important of our postal functions, the rural free delivery being the most conspicuous example and one which I believe should be kept up no matter what its cost, as it is the most important postal service in the entire department. It pays too high a return—as does every other postal service—in improved and elevated citizenship.

I earnestly hope that every reader will give this postal-zone matter and its revival of unsound postal theories that have been discredited for over two generations very serious thought.

INDUSTRIAL EXCURSIONS

AMERICAN CHEMICAL SOCIETY

Philadelphia Meeting

Sept. 2-6, 1919

SEVENTEEN of the representative plants of Philadelphia acted as hosts on the afternoon of Sept. 4 to the members attending the fifty-eighth meeting of the American Chemical Society. Thus a choice was given of seeing one of the elite of the following industries: petroleum, leather, storage batteries, lime, coal-tar products, rare earths, paper, printing, gas, paint, rubber, sugar, phonographs, antitoxins and water. Many of these proved to be of exceptional interest and are therefore included in this continuation of the report of the meeting.

The Atlantic Refining Co.

The works of the Atlantic Refining Co. occupy an area of one square mile, or nearly 1 per cent of the city-county of Philadelphia. Two hundred and fifty-odd stills equipped with condensers and varying in capacity from 600 to 1250 bbl. make up the actual equipment inventory along with 4000 tanks holding up to 55,000 bbl., 825 automobile trucks, seven 11,000-ton tank steamers, hundreds of miles of pipe lines and pumps to correspond. Eleven thousand employees seem to be a small force with which to operate such an enormous works, but everything is done mechanically, with a minimum expenditure of man power. The present equipment capacity is about 45,000 bbl. of crude oil per day, which is received through 8-in. and 6-in. pipes from the various Pennsylvania, West Virginia and Mid-continental oil fields. Various grades of crude are shot through the same line one after the other without having as much tendency to get mixed up as is often exhibited on our rail transit lines. Schedules are made and kept. The arrival of the new crude supply means the quick shifting of a few valves to place it in the right tank, as its analysis has been wired in from its point of shipment and a tank has been provided.

REFINERY PRACTICE

There is considerable variety in the practice of petroleum distillation, owing principally to the variations in the crude oils and the specifications of the two hundred-odd products made.

The following is an elementary outline taken on an average of the progressive distillation and treatment of oil. It must be noted at the start that the composition of an oil vapor is dependent on the partial pressures of all the constituents, which in turn are dependent on their vapor pressure and concentration in the liquid. For this reason the first distillate, called crude benzene, has a little of the whole paraffine series. However, a fractional condensation is made which segregates fairly well the gasoline hydrocarbons from pentane to nonane; the naphtha, from decane to tridecane; and the kerosene, on up to octadecane, etc. Of course all fractions are controlled at the gravity testing house, where hourly Baumé records are kept and the oil piped to the right tank. The speed of the vapor is very great at times, for often 50 bbl. of oil is taken off of a still per hour. For this reason some tarry matter is trained over, which is removed together with unsaturated hydrocarbons by agitating with 66 deg. oil of vitriol in a large vertical lead-lined tank built along the design of a separating funnel. After the acid sludge is drawn off, the oil is neutralized with caustic soda solution, washed with water and steamed.

If the petroleum is a paraffine base, lubricating stock and the waxes begin to come over as soon as the light oils have stopped and the temperature of the still raised. It should be noted that practically all the stills are heated with fuel oil steam jets except in the latest installations, where fine coal screenings are fired with stokers. No arches are used with this type of heating. At first some trouble was found in the combustion gases from the fuel oil condensing on the cold still, but by lowering the fire zone this was overcome.

Evidence that the ordinary distillation process is not one of mere physical separation is found in the fact that if the paraffine residue is chilled, an amorphous non-crystalline solid segregates which is separated and refined under the name petrolatum, vaseline, etc. If this same fraction had been distilled, and the distillate chilled, hard paraffine wax would be the result.

Wax tailings are the last paraffine fraction, leaving coke in the still. Petroleum coke is one of the purest forms of carbon, and is used in making carbon elec-

¹Dill & Collins Paper Mills, pp. 370-375, Sept. 15.

HIGH PRESSURE HORIZONTAL BURTON PROCESS STILLS

trodes. Being free from silica and low in sulphur, it makes an ideal reducer for such metals as aluminum, magnesium, etc., in the electrolytic reduction processes.

Of recent years the Mexican asphalt base crudes have been playing an ever increasingly important role. The light top fractions are taken off in a similar manner to the paraffine crude. The topped residue may be distilled up to 700 deg. F. and sold for fuel oil. If flux oil is desired, the residue is blown with air to dehydrogenate and polymerize the oil hydrocarbons into asphalt. If the air is applied for a sufficient period, the highest grades of asphalt may be produced of any desired melting point or penetration.

THE BURTON PROCESS

Many unsuccessful destructive distillation inventions have left their only trace in the files of the Patent Office, thus giving evidence that they grew to be no bigger than an original idea. James Young, Benton, and Devar & Redwood, all have their supporters as being the real inventors of the destructive distillation of oil, though it is perfectly well known that they could not work the process commercially on account of their lack of equipment facilities. While the original Burton process was eventually operated successfully, it fell to the part of Clark, Hopkins and Humphreys to furnish several much needed improvements. A view of the battery of old horizontal direct-heated stills is given.

HIGH PRESSURE VERTICAL BURTON PROCESS STILLS

Coke deposit formation, with resulting overheating of the still in spots, made it necessary to drop the pressure of the vapors lower than desirable. Clark evolved the vertical boiler tube heater in conjunction with the tall vertical still towers. Boiler tube cleaners are used to cut out the coke layers at the beginning of each run, and in this way a pressure of 100 lb. can readily be obtained, with a corresponding high yield of cracked gasoline. The gases obtained are stored in regular gas holders and used for fuel within the works.

Robert H. Foerderer

At the plant of Robert H. Foerderer, the manufacture of vici kid was observed in the factory which grew to gigantic dimensions during 17 years of patent monopoly and well deserved popularity. Dry salted goat hides in bales of 500 are received, principally from Arabia, India and China. These are sorted, washed, soaked in water to soften and delleshed with scrapers. The hair is removed by leaving the hides several days in vats of old depilating lime liquor, which has be-

"THE HOME OF VICI KID"

come well inoculated with bacteria. The latter act on the embedding skin cells around the hair roots in such manner that when the hide is immersed in fresh lime solution for several days, ammonia is formed, the hides float up and the hair roots become disengaged. After passing the hides through rollers mounted with spiral scrapers to remove all the hair, they are delimed by soaking several days in oropon solution (ammonium chloride and dry hog pancreas). The soluble salts are then washed out, leaving a very porous skin structure saturated with neutral wash water. The hair obtained is graded, the different qualities being used in weaving rugs and carpets, making harness pads and reinforcing plaster.

The two-bath chrome process used for tanning the skins consists of soaking the skins for several hours in a solution of sodium bichromate and muriatic acid in the proportion of 6 and 3 lb. each per hundred of skins. The reaction is:

After the skins have become well yellowed with chromic oxide all the way through, they are greened by soaking in a reducing solution of hypo. This reaction is in three stages:

The basic chloride is then converted to $\text{Cr}_2(\text{OH})_4$ by washing in sodium bicarbonate.

The skins are now dyed, fat-liquored, dressed and glazed, finally being measured in an ingenious segment roller machine, inspected, graded and shipped.

The coated leather department was not visited, though fine specimens of this modern type of leather were exhibited at the office of the company.

The Electric Storage Battery Co.

The plant located at Nineteenth and Allegheny Sts., Philadelphia, is said to be one of the largest of its kind in operation today. The raw materials consist chiefly of pure lead, antimony lead in pigs, sulphuric acid, litharge, red lead, lumber and packing materials. Finished products such as glass jars for small batteries and rubber jars in all sizes are purchased from other manufacturers.

The visitor is immediately impressed with the extent of the lead-working activities, which embrace the larger part of the manufacturing establishment. All battery plates and fittings, terminals, busbars, connections, lugs, etc., are cast in hand-operated molds especially designed and built by the company.

The frames and sections of the plates which will be subjected to stress or strain in operation are cast from antimony lead wherever feasible, to give proper strength. This is particularly practiced in the larger sizes. The small plates and parts adjoining or carrying the activated material in the large plates are made from pure commercial lead, which is later burned to the antimony lead supports in assembling.

A noteworthy item in connection with the lead burning is the type of flame used. It was found unnecessary to employ the intense heat of the oxy-acetylene flame in this work, and the company therefore installed its own water gas plant. Water gas and oxygen are ignited in the torches. Other chemical plants having a considerable amount of lead burning to do might effect a saving through this feature.

There are two general types of grids made: The pasted grid, made up with a sort of mesh into which the red lead is plastered by hand to form a smooth surface, and the button or Manchester grid, which consists of an antimony lead plate punched with holes about $\frac{3}{4}$ in. in diameter. These holes then receive a button or roll of pure lead corrugated ribbon forced into place by hydraulic presses. This ribbon is made by extruding lead from the cold ingot at a pressure of 300 tons, resulting in a dense product. Large rolls similar to those employed in steel mills make the sheet lead from the pig for use as battery box linings.

The department for the making of wood separators used between plates covers considerable space and consists mainly of chemical processes. Cypress, cedar or California redwood is used and is first placed in a bath of hot alkali for several hours. From this it is taken through tanks involving about 20 operations which were not revealed to the visitors. The purpose of the process is to make the wood resistant to deterioration in the sulphuric acid bath of the battery.

The pasting of red lead on the grids is carried on by hand with a large number of workmen. The material is damp so there is little dust to cause lead poisoning. The men are required to have special suits of clothes furnished by the company and are forced to take at least one shower bath each week.

There is a large wood working plant which turns out boxes for the wood type storage cells. This shop makes only special sizes, as the company has found it cheaper to buy the others on the outside. The machine shop is large, due to the fact that the company makes its own factory equipment as well as the small metal parts, other than lead, for the battery outfits. The steel and copper parts are lead plated before assembling.

A variety of operations are carried on in the assembling departments. The individual plates are gathered in small racks where the busbars connecting a set for each cell are put on by the lead burners. The busbars are cast in hand molds in the same department. The sets thus formed are placed in the boxes which have been previously constructed and painted with asphaltum paint, in case of wooden containers, and the covers put on. The mechanical part of the cell thus completed is taken to the charging or activating department.

Several large rooms are in continuous operation where the acid is placed in the cell and the charging is carried on. Other large batteries of tanks are subjected to current for activating unassembled plates. The current for this work is supplied from a 2000-kw. steam-power plant supplemented by three substations receiving an additional 2500 kw. in power from the Philadelphia Electric Co.

The visitors witnessed the complete process of manufacture of several types of storage cells. One of these was the lighting set made for the Cadillac automobile, said to be one of the best turned out by the company. Another was a glass jar, 16 cell, farm lighting set built with the view of being assembled and put in operation by the layman. This set contains a pilot cell with a depression molded in the glass side about an inch in width and extending vertically along a part of the height. When the battery is in operation a composition ball of proper specific gravity floats in this slot, forming a hydrometer. When the ball is near the bottom of the slot the operator knows it is time to start his generator and when near the top the completion of the charge is thereby indicated.

The cell most worthy of mention, however, is that manufactured for submarine boat propulsion in the U. S. Navy. This cell is made with extreme care under the vigilant supervision of Government inspectors, who carry on exhaustive tests to determine its performance on completion. The large units are assembled in rubber jars, the completed cell weighing 2200 lb. Each battery for the new S type submarine is made up of 120 of these cells arranged in two equal groups for either independent or combined operation in propelling the boat.

The laboratories include a chemical laboratory, in which all raw materials are analyzed; a process laboratory, in which manufacturing methods are perfected; a research laboratory, for development work; a commercial laboratory, in which batteries are tested to determine their characteristics and life, and an engineering laboratory, in which auxiliary apparatus is developed and tested.

A thorough study of the work done in this plant would be well worth the time of anyone interested in either mechanical operations or electrochemical work relating to the operation of the storage battery.

HYDRATING AND ROTARY LIMEKILN WORKS

Cedar Hollow Limekilns

Three types of limekilns are operated in the Cedar Hollow plant of the Charles Warner Co. at Devault, Pa., the visit to which proved to be very instructive as well as a delightful excursion of 30 miles up the Chester Valley. For the benefit of those who think of the burning of limestone in the simplified symbols of CaCO_3 , less CO , produces CaO with a little thermo and equilibrium chemistry thrown in, these few notes are designed to furnish somewhat of an appendix to their knowledge.

The decarbonating process of the dolomitic limestones begins as low as 660 deg. F. After all the CO_2 has been removed, which is around 2100 deg., the lime begins to harden. Only about $1\frac{1}{2}$ per cent of acid fluxes (SiO_2 , R_2O_3) are present in the raw stone, which reduces the tendency to sinter, but the lime structure apparently changes, becoming less porous, at a rate increase proportional to the magnesia content. The stone at the Cedar Hollow quarry is dolomitic, the ratio of lime (CaO) to magnesia (MgO) being very close to 3 to 2. This is very important in connection with the slaking properties of the product. Pure calcium oxide, as is well known, has to be added to its slaking water, because it is so porous, and thus reactive, that it will "burn" itself with the heat of reaction of the hydration. Probably this so-called "burned slaked lime" is a lower hydrate; at any rate, it is non-plastic, gritty, and cannot be used for plaster.

On the other hand, a dolomitic burned lime, being of a denser structure, can safely be slaked by adding water to it. This is a very desirable feature in the building trade, as it makes it easier to regulate the consistency and quality of the lime paste.

However, another peculiarity should be noted, and that is that if hard burned dolomite is added to a large bulk of water, the slaking reaction is very slow, because sufficient heat is not spontaneously generated to give the temperature required for the high-velocity reaction throughout the mass. Variations in the degree of burning, soft, medium and hard burned, depend on the period of firing, and, in turn, the size of the rock and the type of kiln.

The terms dead, hard, medium, and soft burned, as applied to calcined dolomite and magnesite products, are primarily descriptive from a chemical activity point of view. Neither pure CaO nor MgO is fusible at atmospheric pressure, for their boiling points are below their melting points. However, on the same physical principle as exhibited in the case of alloys, etc., their

melting points, or better, softening and cohering temperatures, are lowered by the association with foreign materials. In the case of magnesite, it has been found necessary to have several per cent of ferric oxide present to produce a dead burned refractory of dense enough structure to withstand slag corrosion. The same reasoning is applied in using a soft burned pure CaO for fluxing ores, for it has a porous structure, the pores being the space occupied by the CO_2 , burned off, and offers a maximum reaction area to the silica, phosphate, etc., to be slagged. Thus it will be seen that the physical structure of these materials is of primary importance and that it is dependent on the chemical constitution together with the heat treatment given.

CEDAR HOLLOW QUARRY

The quarry has been worked on a 40-ft. face over an area of about 25 acres. Recently a drainage tunnel about 800 ft. long was cut in so as to carry off the water from the second level, which will be 50 ft. lower than the floor of the original quarry. Better quarrying conditions cannot be conceived, as a floor of several million tons of virgin rock has been stripped of overburden and drained of surface water at what might be called a cost too negligible to take into account.

In the run-of-quarry blasted rock, all gradations of sizes are produced. Stone for lump lime, known as "one-man stone," i.e., pieces that can conveniently

QUARRY AFTER A BLAST

15-TON KILNS AND STORAGE TANKS

BATTERY OF SEVEN 10-TON VERTICAL KILNS

be handled by one man, are hand picked in the quarry and loaded upon quarry cars for transportation to the kilns. For best results in burning, a kiln charge must be fairly uniformly sized so as not to get too hard a burn with smaller pieces and at the same time leave no carbonate centers in the larger ones. The large rocks are broken up into "one-man stones" and graded to size.

The smaller pieces of stone, known as spalls, are crushed in a gyratory to pass a $\frac{3}{4}$ -in. mesh screen. The material running less than $\frac{3}{4}$ in. goes to the pulverized stone plant, where it is dried in a direct-fired rotary drier, pulverized in a Fuller-Lehigh mill and bagged through automatic packers. Over 85 per cent will pass 100 mesh. The pulverized stone is used in agriculture to counteract soil acids and to increase the porosity of heavy clay land. Of recent years great amounts have been used in filling tar and asphalt pavements. The $\frac{3}{4}$ -in. stone is burned in a rotary kiln and slaked at the hydrating plant.

TYPES OF KILNS

The present equipment consists of seven 10-ton vertical brick, two 25-ton vertical brick, seven 15-ton steel jacketed kilns with direct coal firing, also one 50-ton vertical steel jacketed, and one 100-ton rotary kiln, each fired with producer gas. A vertical Mount kiln with rotating base is now in the course of erection, which is expected to increase the output 100 tons per 24 hr. of firing, thus giving a daily production of about 450 tons per day of burned lime.

The rotary kiln is used to burn the smaller sizes of stone, making the conversion in $2\frac{1}{2}$ hr. Due to the short time of firing, the product is very soft and slakes quite rapidly, not having had time for the magnesia-lime condensation reaction referred to previously. It is pulverized and then slaked in a machine which proportions the correct amount of powdered lime and water conditions most favorable to give a high quality of product—called by the trade name of "Limoid."

Surplus burned lime product from the vertical kilns is mixed with the rotary product and the resulting mixture is used in making "Limoid" (hydrated lime). All Warner hydrated lime is seasoned in steel tanks for at least three days before finishing and shipping.

To produce a super quality of hydrate, the burned lime is specially hydrated and then finished in an air pulverizer, so that there are no tailings in the finished

material. This is called "Kreme-Kote" and is used for high grade finishing plaster.

The vertical kilns are used for making lump lime and require from 24 to 72 hr. for conversion to medium burned lime having easily regulated slaking properties. The trade preference in some localities for lump lime was established in the days when the stone was burned directly with wood and coal fuel. Ancient practice was to sort out all the clean lumps, and sell the smaller pieces along with the fuel ashes for fertilizer. However, as a rule, small sizes usually indicated overburning with corresponding slaking trouble on the job and the trade now refuses to take time to investigate by running any slaking tests.

As long as there is an appreciable core of unburned stone, lumps in the kiln show dark spots against the incandescent mass. On cooling, lumps containing "core" (center of undecomposed stone) show a pink or salmon pink tint on the surface. Experienced lime men can make an infallible separation between properly burned and incompletely burned lime by this color test. This color test is applicable only to dolomitic lime.

COAL CONSUMPTION

Vertical kilns are the more economical in fuel costs, giving from 4 to 5 tons of lime to the ton of coal, as compared with 3 to $3\frac{1}{2}$ tons with the rotary, in spite

MANIERRE BOX CAR LOADER

of the difference in the length of time of heating. Of course the greater production of the latter in proportion to the overhead costs counteracts the difference in fuel cost considerably. However, the Mount kiln should have the heating advantages of the stationary producer gas fired vertical and the controlled feeding of the rotary kiln. Forced firing and fast lime burning go hand in hand, but exit gases over 400 deg. indicate an uneconomical heat leakage, unless greater production must be had because of market activity.

Large steel tanks having a combined storage capacity of several thousand tons act not only as an inter-department regulator but as a seasonal reservoir. The plant is excellently equipped with conveyors, dump cars and machine car loaders. Fluctuations in shipping from none to 30 cars per day are thus readily provided for. A view is given of the first Manierre box car loader, installed in 1913, at work. The loader itself is an ingenious but simple belt conveyor, so carefully balanced on ball-bearings that one man can easily project it through the car door and into place. The end of the conveyor is raised or lowered so that the first lime charged into the car is deposited easily on the car floor with a minimum of breakage. As the pile builds up, the end of the conveyor is raised so that the drop of the lime is always a minimum.

The Barrett Company

The Frankford, Philadelphia, Works of the chemical department of the Barrett Company has grown out of the business originally started in 1884 by Dr. H. W. Jayne. In 1886 Dr. Jayne formed the partnership of Jayne & Chase, manufacturers of fine chemicals.

In 1887 the H. W. Jayne Chemical Co. was incorporated, specializing in refined coal-tar products such as naphthalene, carbolic acid, benzol and nitrobenzol.

In 1896 the H. W. Jayne Chemical Co. was one of the companies which formed the Barrett Manufacturing Co. Dr. Jayne was appointed manager of the Frankford plant, and held that position until his death, in 1910. The business in refined products from coal-tar has grown steadily along the lines originally laid down by Dr. Jayne. Many of the processes in use at the present time were worked out by him.

The plant has grown from a very small one, covering about three acres, to the present works, covering 17 acres.

An extensive research laboratory is maintained for the development of new products and the perfection of old processes. Practically the entire plant has been rebuilt during the last four years. To-day, with its up-to-date power plant, fire-fighting equipment, service buildings, dispensary, shops, etc., it is representative of the most modern type of chemical works.

The Frankford Works is essentially a refining plant and does not handle any crude-tar distillation. One of the principal processes is fractional distillation, the plant having an equipment of 35 column stills, varying in capacity from 1200 to 10,000 gallons.

In the distillation of coal tar several fractions are cut, the actual operation being somewhat different for different plants. In general the first cut obtained is known as light oil and contains all of the benzol, toluol and xylol in the tar and some of the tar acids, pyridine bases and naphthalene. The second fraction, or carbolic oil, contains almost all of the naphthalene and tar acids and the bulk of the pyridine bases. The naphthalene is sometimes allowed to crystallize out of this oil and separated by centrifuging as a crude naphthalene. The tar acids are also sometimes extracted with caustic soda and the carbolate so formed decomposed with carbon dioxide, giving crude carbolic acid. The fraction following the carbolic oil is known as creosote oil and is used largely for creosoting purposes. A fourth fraction, known as anthracene or heavy oil, is sometimes taken off, this fraction on cooling crystallizing out a crude anthracene.

The chemical department of the Barrett Company takes as its crudes, light oil and carbolic oil from other plants, crude naphthalene and crude carbolic acids already removed from the carbolic oil and crude anthracene obtained from the heavy oil. In addition to this there are worked up several miscellaneous oils from outside sources, such as drip oils from gas works, coke oven light oils, etc.

The following discussion attempts to take up the processes as carried out in the various buildings in as nearly as possible the order in which they take place.

LIGHT OIL FRACTIONS

The light oil department consists of a battery of fire-heated fractionating stills equipped to run under vacuum, the fractionating columns being according to Barrett design, but following the general construction

LIGHT-OIL FRACTIONATING STILLS

of containing a number of plates, each plate being provided with a considerable number of cone and bell arrangements, so that the upcoming vapor passes up through the cone and must bubble down underneath the bell through a layer of liquid on the plate. The plates are kept washed down continually by a flow of liquid condensate fed from a partial condenser or dephlegmator situated above the top of the column. The light oil stills form a starting point for the cruder oils received, light oil, carbolic oil, drip oil, etc., being distilled here. The plant produces crude benzol, crude toluol, crude solvent naphtha, which are further worked up elsewhere, and also a fraction from carbolic oil containing nearly all the tar acids and naphthalene. The residue from the stills is a tarry liquid and is accumulated and burned as fuel under the stills.

The distilled oils from the light-oil stills containing naphthalene are collected and allowed to cool in large shallow pans. Here the bulk of the naphthalene separates out and is separated from the oil by draining and centrifuging. The naphthalene so produced is crude naphthalene and is worked up at a later stage.

The equipment of the benzol house is a battery of column stills heated by steam and run without vacuum. The plant receives the crude benzol and crude toluol fractions from the light oil stills together with some of the closer boiling light crudes received in the plant. These crude fractions are first given a wash treatment with sulphuric acid in order to remove the unsaturated compounds, the wash taking place in vertical agitators. Following the sulphuric acid wash the materials are given a wash with caustic soda solution to free them from any sulphuric acid and are then charged into the stills. The stills are run to produce pure benzol, pure toluol and intermediate fractions which are redistilled. Products such as 90 per cent benzol are also made here.

The xylol department adjoins the benzol house, being separated from it by a fire-wall. The building and equipment are the property of the United States Navy. The plant was erected during the war to produce a pure meta-xylol for nitration to TNX (trinitro-xylol). The stills are exactly similar to the benzol stills, the operation followed out being a distillation of a crude xylol fraction after washing to produce a meta-xylol of very close boiling range.

The Cumar plant involves three distinct operations, the first of these being the treatment of the "naphthalene-free" oil from the light-oil pan house for the removal of tar acids and pyridine bases. The tar acids are extracted from these oils in large vertical agitators with caustic soda solution, the carbolate so formed being finally allowed to settle and drained off. The pyridine bases are also extracted in special lead-lined agitators with dilute sulphuric acid. The pyridine sulphate solution so formed is removed in a similar manner to the carbolate. The agitators in this plant are also used for making up the more special tar acid containing oils, such as flotation oil, dip oil, etc., where the tar acid content must be very closely adjusted.

The second operation which takes place in this plant is the treatment of the fractions containing coumarone and indene from the light-oil plant to produce solvent naphtha, hi-flash naphtha and "Cumar" resin. The operation here consists of agitating the fraction to be treated with a small quantity of sulphuric acid, this treatment producing a polymerization of the coumarone, indene and similar materials in the oil. The polymerized product so formed stays in solution in the oil, which is separated from the acid and washed with caustic soda in order to entirely free it from acid. The oil is then subjected to distillation in steam-heated stills, the unpolymerized naphtha distilling over and leaving behind in the still a resinous residue known as Cumar resin. This resin, after all of the volatile oils have been removed by distillation, is drawn out into destructible drums and is ready for marketing.

The third operation carried on is the manufacture of emulsifying disinfectants. These products consist of a coal-tar oil, a soap, tar acids and water. In the cheaper grades of material the soap is a rosin soap, the process for the manufacture of the disinfectant

BENZOL STEAM STILL; WASHER AT RIGHT

OPERATING PLATFORM BENZOL COLUMNS

being to introduce together into the disinfectant pot the requisite amount of rosin, caustic soda, oil and tar acids and heat until the mixture is entirely homogeneous. The oil used in these compounds is the naphthalene-containing fraction after treatment for removal of naphthalene in the light-oil pan house and the freezing plant. For the higher grades of disinfectants the rosin soap is replaced by other soaps.

The object of the freezing plant is to remove the last traces of naphthalene from the naphthalene-containing oils after extraction in the Cumar plant. This is done with a view to obtaining oils which will not separate naphthalene on standing even at low temperatures. The oils are run into brine-jacketed agitators and are cooled down to a temperature of about $-20^{\circ}\text{C}.$, the separated naphthalene being subsequently removed by running the oil through a centrifugal separator.

CRUDE CARBOLIC HOUSE

In the crude carbolic house the tar acids are recovered from the carbolate obtained in the Cumar plant. The process consists in an evaporation of the carbolate to the required concentration and blowing with carbon dioxide produced in small limekilns. The blowers are run in series, the fresh carbon dioxide entering first into the nearly saturated carbolate. The tar acids so

produced separate in a layer and are allowed to settle and are drawn off. The crude acids are prepared for fractionation by heating in a simple still until the water is driven off. The aqueous carbonate solution is re-aqueousified in a small horizontal agitator with milk of lime, the caustic mix so produced being filtered, giving a caustic solution which is used again for extraction of tar acids.

LIGHT-OIL ACID STILLS

The light-oil acid stills are fire-heated column stills similar to those in the light-oil department and are used largely for the fractionation of crude carbollic acid. The acid is distilled under vacuum and several cuts made containing various percentages of phenol and the cresols and xylenols. The fractions produced in this plant are accumulated and redistilled in the acid stills.

The acid stills consist of a battery of steam-heated column stills equipped to be run under vacuum, and handle the fractions produced in the light-oil acid stills together with some of the more refined crude carbollic acids. The plant produces a crude phenol, crude orthocresol, crude U.S.P. cresol, which is principally a

REFINED CRYSTALLIZED NAPHTHALENE

mixture of meta- and para-cresols, together with some of the mixtures of higher boiling tar acids.

REFINED CARBOLIC ACID

In the refined carbollic acid house the crude phenol from the acid stills is subjected to a recrystallization treatment by mixing with a small percentage of water, allowing it to crystallize in ice cans and crushing and whizzing these cakes. The crystals so produced are of a high purity, but contain some water, which is separated from the phenol by a subsequent simple distillation. The cresol fractions are also subjected to a simple distillation in this plant, the principal object being to improve their color.

NAPHTHALENE

The crude naphthalene received from outside sources is melted up in a tank together with the crude naphthalene produced at this plant. The melted naphthalene is run out into large shallow pans in the pan house and allowed to cool slowly, the effect being a recrystallization of the naphthalene from the oil. The solidified naphthalene is broken out of the pans and subjected to the next stage of the process.

NAPHTHALENE CRYSTALLIZING PANS AND CONVEYOR

The crude naphthalene from the pan house is crushed and subjected to a whizzing treatment, this treatment removing the bulk of the adhering oil. The naphthalene is finally washed in the whizzers with a small quantity of warm water in order to complete the removal of the oil.

The purified naphthalene obtained from the whizzer is charged into fire-heated simple stills and subjected to distillation. The middle fraction of the distillate is accumulated and charged molten into lead-lined agitators with sulphuric acid with the idea of freeing the naphthalene of unsaturated compounds. After the sulphuric acid wash the still molten naphthalene is washed with caustic soda solution in order to free it from sulphuric acid and is then charged into the refined stills and subjected to redistillation. The bulk of the middle fraction from this redistillation is run to shallow pans and allowed to solidify. A portion of this naphthalene is used for subliming.

The naphthalene is broken out of the pans, after solidifying, with a pick and shovel and is crushed, the bulk of the crushed naphthalene so produced being packed as such. A portion of this material is run to the ball machines and other special molding machines, and is molded into the various forms demanded by the trade.

NAPHTHALENE FLAKE HOUSE

For the production of sublimed naphthalene, the refined distilled product is charged into deep pans situated at one end of the house and heated by steam-coils. The naphthalene sublimes from these into large rooms, where it condenses in the form of flake. These flake houses are run for considerable periods at a time and are then opened up and the flake naphthalene produced shoveled up and packed.

ANTHRACENE PLANT

The anthracene plant receives crude anthracene from other plants of the Barrett Company and works it up into refined anthracene and carbazole. The process followed for the purification of anthracene is to wash the crude with solvent naphtha in horizontal agitators, filter the mixture so produced and subject the washed anthracene cake to a similar treatment with pyridine. The solvent treatment has the effect of removing the adhering oil and the bulk of the phenanthrene, the

NAPHTHALENE SUBLIMING HOUSE

pyridine treatment being principally for the removal of carbazole. The anthracene cake so produced is subjected to sublimation in a fire-heated pot in a current of air, the sublimed anthracene being collected in a large chamber and shoveled up and packed.

The pyridine liquor obtained from the pyridine wash of the anthracene contains most of the carbazole and is worked up for carbazole by distilling off the pyridine, washing the residue so obtained with solvent naphtha and subliming the crude carbazole so produced. The products of this process are an 80-85 per cent sublimed anthracene and an 85-90 per cent sublimed carbazole.

SYNTHETIC PHENOL PLANT

The synthetic phenol plant was constructed during the war to supply phenol for the manufacture of picric acid. The process followed was the Dennis-Bull and has been fully described in the chemical journals. The plant has now ceased operations.

BOILER HOUSE

The boiler house equipment consists of four 500- and one 250-hp. B. & W. boilers and one 250-hp. Erie, giving a total boiler-horsepower of 2500. The boilers are equipped with Murphy stokers and with Cochran feed-water heating system.

FILTER PLANT

The filter plant produces all of the water used for such operations as condensing and cooling which is used in the plant. The equipment consists of two batteries of six horizontal sand filters and three centrifugal pumps and has a total capacity of 6,000,000 gal. per day. The water so produced on account of the filthy nature of the source is not suitable for process work nor for the boilers, for which the plant is also equipped with a supply of Philadelphia city water.

LABORATORY

The laboratory building is a three-story structure housing both the routine control laboratories and the research laboratories. The first floor is mainly occupied with offices, washrooms, etc. The second floor is given over to the routine plant control work, and the upper floor is divided into several individual laboratories devoted to research work.

NAPHTHALENE BALL MACHINES

BIRDEYE VIEW OF WELSBACK CO. PLANT

The Welsbach Co. Plant

The manufacturing plant of the Welsbach Co., located at Gloucester, N. J., just across the Delaware River from Philadelphia, Pa., is a development of many years of commercial operation and chemical research in the incandescent gas mantle industry, and the processes now employed therein are representative of the present state of the art. The manufacturing operations are resolved into three main departments, namely, mantle manufacture, fixture manufacture and chemical production. Each of these departments is subdivided into units, and a thorough inspection of the workings as a whole reveals an enormous amount of detail. The diversity of this detail at once seizes and holds the interest of the visitor.

MANTLE MANUFACTURE

The first step in making the gas mantle is the knitting of the cloth tubing or webbing to form a base for the physical shape of the mantle on which the thoracera mixture is to be constructed. This tubing is woven from ramie fiber thread, produced from the ramie plant, similar to linen and a native of India; cotton thread and silk thread. Ramie thread is used for inverted mantles, cotton for upright mantles and silk for the highest grades of either type. Silk is by far the best fabric, leaving the smallest amount of foreign ash in the finished product. Automatic knitting machines, employing both the chain and the rib stitch, weave the tubing into long lengths, made endless by hand sewing, and the diameter of which is considerably greater than the ultimate diameter of mantle desired. This is to allow for shrinking of the structure during subsequent process of hardening. The machines are manufactured by the Wildman Mfg. Co. and the knitting department has a capacity of 20 miles of tubing per day, consuming 1500 to 2000 lb. of thread, or, in other words, enough fabric is manufactured for the production of 1,000,000 mantles per week.

The washing room adjoins the knitting department and the air for both is so thoroughly purified by a Carrier Engineering Corporation washer that it is impossible to detect any particles of solid matter floating in the sunlight as under ordinary circumstances.

The water used in washing the tubing and for dilu-

tion of the chemicals so employed is of extreme purity, being continually tested, and if over 5 parts of solid matter in one million parts of water is in evidence, the whole is discarded. This is an important detail, since any appreciable amount of foreign matter entering the flow weakens the finished mantle and causes its rejection by the inspectors. The water is therefore distilled in a J. P. Devine Co. multiple effect apparatus located in the power house and conducted to the various departments through tin lined lead pipe. About 20,000 gal. is consumed daily in the washing process.

The washing room operation requires four days' time to thoroughly cleanse the fabric. The equipment consists of six large circular tanks with smaller auxiliary vats and Troy Laundry Machinery Co. centrifugal wringers. Overhead revolving spools are used to convey the webbing through the process.

After a final neutralization and drying in the centrifugals the material is conveyed to a large Proctor drier, manufactured by the Philadelphia Textile Machinery Co., and remains therein about 25 min. at a temperature of 130 deg. The drying process is continuous, with the material moving along through the dry box on revolving spools.

DEVINE WATER DISTILLING APPARATUS

The saturating department receives the webbing and soaks in a solution of approximately 99 per cent thorium nitrate and 1 per cent cerium nitrate, the time in the bath being from 15 to 30 min. Between 30 and 40 different solutions are used for various mantles and selection depends on the type of product and raw material involved. A colored dye is added for tracing various lots through the factory. The work is carried on in small rubber boxes to the end of which are attached hand wringers, for partially drying.

The wet material from the wringers is cut into 90-in. lengths and slipped over wooden poles by hand. Care must be taken to stretch the mesh of the fabric evenly along the pole. The poles are then hung in a large drying room for a 30-min. period, and where the wet bulb temperature 110 deg. F. and the dry bulb temperature 80 deg. F. is maintained by thermostatic regulation. Curve drawing recording meters are installed at all such locations throughout the factory. The recorders and thermostats are furnished by the Tycos Co. Bristol recorders are also extensively used.

ELECTROPLATING DEPARTMENT

eration is 15 to 20 min. at a temperature of 80 deg. C. This coating protects the ash against breakage until it is burned off in the lamp of the consumer. The department operates four banks of three machines each, and delivers the trays of mantles ready for packing. The collodion fumes from the drying boxes are recovered by small exhausters, shown located over the boxes, and returned to the collodion plant for absorption. An annual saving of about \$10,000 is effected through this feature.

The packing and assembling of the finished product embraces a complete system of belt conveyors and elevators for delivering the numerous types of boxes to overhead bins and for placing the finished package in the shipping department. The best grades of upright mantles are placed in nichrome wire supports before packing.

As the packing is in progress the preliminary inspection is carried on and rejects are sent to the final inspector, who destroys all imperfect ones by crushing in the hand. No secondary products are marketed. This rejection of defective mantles is an indication of the high quality of the article sold to the consumer. The majority of defects is due to the unavoidable entering of impurities into the early stages of the process.

A complete paper box factory makes all forms of packing containers, including the printing of labels. The paper tubing is produced from strawboard 0.017 in. thick in 10 to 15 ft. lengths and of all diameters. The company has experimented long to arrive at the proper glue for this tubing and has finally obtained a

FEEDING TRAYS OF MANTLES TO AUTOMATIC DIPPING MACHINES

The dried lengths are placed flat in bundles and cut to mantle length by rotating knives. The open end of a mantle is dipped in fixing solution by machinery, the drawstrings of asbestos or treated thread are put in by hand and the finished structure is sent to the hardening rooms.

There are two divisions of the hardening department, one for the upright and one for the inverted mantles. Hardening is accomplished by placing over gas flames where a mixture of gas and air is carefully regulated. In the case of upright mantles the regulation is accomplished by hand work of skilled operators over multiple bunsen burners. The burning of inverted mantles is automatically regulated in multiple crucibles. The shrinkage occurs during this process and a 3 per cent loss of product is incurred in the upright mantles, with a 30 per cent loss in the inverted type. This department consumes 160,000 cu.ft. of gas daily.

The mantles, now consisting of an ash of thorium and cerium oxides, are carefully conveyed in trays, 100 per tray, to the dipping and packing room. These trays enter the automatic dipping and drying machines, manufactured by the Welsbach Co., where the collodion coating is put on and dried. Time required for this op-

CHEMICAL PLANT

COTTON NITRATING PLANT

satisfactory article in a cold glue, made from potato and tapioca dextrines. (Arabol Co. glue No. 4604c.)

The paper caps for the circular boxes are drawn from circular stamped blanks, the cutting and drawing operation being accomplished on the same punch press. In order to draw these caps successfully it is necessary first to soften the rolls of strawboard by moistening with a mixture of equal parts of tallow and soft soap. This mixture is made in a small tank overhead and applied by passing the strawboard ribbon over a roller which dips in a small vat of the solution, before being fed to the presses.

The rectangular paper boxes are produced on both automatic and hand-fed machines. The smaller sizes are carried to their respective wire mesh bins by air suction, or by belt conveyors to the packing depart-

ment. Fifty to 60 tons of paper scrap is recovered and baled each week. The printing department is completely equipped with cylinder and platen presses.

This factory employs the Brightwood box machine, the Inman box machine, the Knowlton stay machine and metal edge machines made by the National Metal Edge Box Co. The Welsbach Co. has also manufactured a number of the automatic box machines in operation.

FIXTURE MANUFACTURE

An extensive fixture factory produces all types of fixtures and fixture parts required by the gas illuminating trade, from the smallest mantle supports to the latest type of indirect lighting bowl. The pattern shop and foundry makes malleable iron, brass, aluminum and composition castings. One section of the machine shops contains automatic screw machines and multiple spindle drill presses; another contains batteries of punch presses, and the third a number of lathes. A complete tool-making department is operated in con-

COLLODION PLANT

junction with these shops. A sheet metal department manufactures the necessary fixture parts.

The electroplating department is capable of producing any desired finish on the fixtures and protecting with suitable lacquer. One of the most recent developments in this work consists of a tumbling barrel, equipped with electrodes for plating while the polishing operation is in progress. The wooden barrel revolves with the axis supported at an angle of about 45 deg. One electrode is attached to the revolving mechanism while the other is suspended vertically in the solution through the open end of the barrel. This is shown in the background of the picture.

The fixture assembling rooms occupy a large floor space and it is here that minor machine operations are carried on and the manufactured parts are assembled to produce the completed fixture.

The machine shop employs Brown & Sharpe hand and automatic screw machines, Warner & Swazey hand screw machines, and Avery drill presses. The power punch presses are of three makes, namely, Ferracute, Bliss, and Henderson. Foot presses are made by Waterbury and Farrel companies.

The section of the works which is perhaps of greatest interest to CHEMICAL & METALLURGICAL ENGINEERING readers is that in which collodion is made and where

ALCOHOL STILL

the rare earths in the form of monazite sands are reduced to secure thorium, cerium, mesothorium and radium compounds.

Collodion, as used to hold the physical structure of the thoria-ceria mantle intact during commercial handling, must have special characteristics to serve this purpose. It must be non-shrinkable when drying, otherwise the oxide structure would be destroyed and the mantle would crumble when collodion is burned off by the ultimate consumer. It is further necessary that collodion be pure and a reliable source of supply be at hand.

The plant produces from 10,000 to 15,000 kilos per month, the entire amount being used in the mantle factory. The cotton is nitrated under cleanest possible conditions, dried in a centrifugal wringer and the process carried to final conclusion in an apparatus of collodion plant, as shown.

The feature most worthy of note is the method employed in conducting the collodion to the dipping machines. The piping system is made up of double pipe and fittings throughout. The inner pipe carries the collodion, while the annular space between the inner and outer metal is filled with inert gas (CO_2) under higher pressure than that required to force the liquid through the inner pipe. In case of leak in the inner wall the gas will enter the central conductor and force the collodion back to the tanks. While this system is expensive to install, it is considered invaluable as an insurance against accident where explosive or inflammable liquids are transported. It is said to be required by law in Berlin where gasoline is stored in excess of 5 gallons.

An alcohol still is operated in connection with this plant, while ammonia is also distilled in an adjoining room. The product of the latter is used in the fabric washing process.

RARE EARTH REDUCTION

The monazite sands consumed at the present time are purchased in Brazil, where they can be obtained more cheaply than the Welsbach Co. can mine them from its Carolina properties. This is due to the fact that the latter deposits are in widely scattered pockets and economical mining operations therefore do not obtain. The ore, or beach sands, occurring in placer deposits near the coast of Brazil is subjected to wet

MONAZITE SAND DIGESTORS

concentration over jig tables, where the monazite, being the heavier, is separated out from the gangue or silicas. The concentrate, however, still contains the garnet, and after being dried a further separation is made by electromagnetic means in a manner similar to that employed in the zinc industry.

The final product shipped contains about 90 per cent of the monazite crystals which were present in the crude ore, and is in the form of a rather uniformly grained, fine, yellow sand. A typical analysis of this product shows the following content:

	Per Cent		Per Cent
Phosphoric anhydride	28	Thorium oxide	5
Cerium oxide	30	Yttrium oxide	2
Lanthanum oxide	14	Iron oxide	5
Neodymium oxide	16	Calcium oxide	
Praseodymium oxide			
			100

The sand is received at the Welsbach works in 100-lb. bags containing 5 to 6 per cent of thoria, the substance most desired in the separation. Definite quantities are mixed with the proper amount of sulphuric acid, with sp.gr. above 66 deg. Baumé, in the digestors, where the mass is agitated under heat for a period of 6 to 8 hours.

The heat is applied below and retained close to the kettle by a sheet steel jacket as shown. The kettle is cast from a special grade of acid-resisting iron. During the heating period, heavy SO_2 fumes are driven off through the cast pipe as shown on the left of the kettle and are conducted to a 16-tube, 85,000-volt Cottrell precipitator. This latter may be seen outside the chemical plant buildings. Its use is necessary to the protection of the surrounding community from the fumes, and a considerable quantity of acid is also recovered.

When the operation is completed, the heat is shut off, but the agitator is kept running, and the tee in the SO_2 line is disconnected from the kettle. The top cover is also removed for the pouring. The removal of the tee permits the apparatus to be turned on its trunnions, in a manner similar to the operation of a bessemer converter, and the pasty mass, consisting of phosphates and the sulphates which have formed, is dumped into a lead-lined receiving vat. This vat, located on the side opposite that shown in the picture, with its top about 1 in. from the floor level, is filled with water at the time of pouring.

The solution is pumped from these vats, one for

PRECIPITATING TANKS

CAUSTICIZING TANKS AND SPERRY FILTER PRESS

each digester, to the second floor tanks, where it is further diluted. This dilution precipitates the rare earths (about 70 per cent of the sulphates and 3 per cent of the phosphates), which are separated from the liquor in Sperry filter presses on the floor below. The sludge then enters a long series of operations, requiring several weeks, carried on in circular tanks with mechanical agitators. Part of this work involves boiling with caustic to produce hydrates, the object of the whole performance being to remove the residual phosphates. These hydrates are eventually dissolved in hydrochloric acid to form chlorides.

It is about this point that the separation of the thorium and cerium compounds is made, and the large part of the work from here on consists of refining the thorium and such quantity of the cerium as is required. The equipment embraces several batteries of glazed earthenware bowls, made by General Ceramics Co., placed under mechanical stirrers as shown in the picture. Practically all the moving parts of this apparatus were made in the company's shops. A new caustic recovery evaporator made by the F. D. Stokes Machine Co. has just been installed.

When the thorium group is split off from the cerium, about 95 per cent separation of thorium present is recovered. The radium and mesothorium comes down with the thorium. The cerium residue is about 50 per cent pure and is known to the trade as commercial cerium. It is sold to the carbon manufacturers for use in flaming arc lamp carbons. Its presence in minute quantities greatly adds to the incandescent light in both mantles and carbons. It is also purified and used in medicines such as cerium oxalate. The Welsbach Co. prepares these compounds for the market. The cerium nitrate used in the mantle fluid is necessarily refined to a purity equaling that of the thorium nitrate.

The complete process from the time the sand is placed in the digestors until the pure $\text{Th}(\text{NO}_3)_4$ is extracted consumes a period of from 2 to 3 months. The plant produces 10,000 to 15,000 kilos per month. Quantities are shipped to Great Britain at the market price of about \$10 per kilo. This trade was built up when the supply from Germany was cut off at the beginning of the war.

The supply of radium from Colorado ores is limited and practically the entire output is required for medical purposes. The manufacturers of articles like radiolite

watches are therefore forced to search elsewhere for the raw luminous material. The Welsbach Co. has successfully undertaken the manufacture of a mixture of radium and mesothorium to supply this need.

An examination of the chemistry of these two substances reveals parallel characteristics and compounds. The principal difference in the two lies in the fact that the activity of mesothorium continues about seven years, while radio-activity is constant over several hundred years.

The extraction from the rare earths begins in the thorium plant and a residue of approximately 20 lb. per day is obtained from the thorium purification process. This residue is taken to the radium laboratory, where it is dissolved as a chloride in the so-called zero kettle. From this it is taken through a series of 5 pairs of steam-jacketed kettles, Elyria Enamel Products Co. make, then through a similar set of evaporating dishes. The work consists of a series of precipitations and crystallizations.

The final residue from the chloride solutions is then redissolved as a bromide and the process continues as before, but on the laboratory bench. The solutions pass through about 30 operations in all. For each ton of monazite sand originally treated there is produced one milligram of the rare element mixture.

OTHER DEPARTMENTS

The company generates power from coal delivered to the bunkers by barge on the Delaware River. Bucket elevators and belts carry to the overhead bins, from which it is automatically weighed to the bank of three Babcock & Wilcox boilers, fired by Riley-Sanford plunger type stokers. Boiler draft is supplied by two Sturtevant fans, direct-driven by steam turbines. The plant is so equipped with measuring and recording devices as to furnish complete data on daily performance. This apparatus includes Hays CO. recorders, Venturi boiler feed water meters, and General Electric steam flow meters.

The engine room contains one 400-k.v.a. 2300-volt 3-phase 60-cycle Crocker-Wheeler Co. generator direct-connected to tandem Corliss engines and with belt-driven exciter; one 150-k.v.a. 2300-volt 3-phase 60-cycle General Electric Co. generator direct-connected to vertical type American Ball engine; one 7-panel switchboard equipped with General Electric instruments, ITE

MIXING BOWLS

circuit breaker and switches, including control for operating the two generators in synchronism during peak load periods.

The laboratory and testing department embraces complete research and control chemical laboratories, and physical laboratories equipped with mechanical devices for shock and tensile tests of mantle materials together with apparatus for candle power and life tests on finished mantles.

The plant buildings are of fireproof construction, with Grinnell sprinkler systems. Distilled drinking water is supplied throughout. A complete hospital is equipped for emergency treatment.

The system of conveying materials requires little hand trucking within the works. The storehouse operates Elwell-Parker electric trucks, equipped with Edison storage batteries, for conveying crates within the building. For heavy outside work Pierce-Arrow 2- and 5-ton trucks are employed. The coal loader shown in foreground of "Chemical Plant" picture is made by the Link Belt Co.

The business of making incandescent gas mantles is said to be continually on the increase in this country. Ten per cent of the Welsbach Co.'s output is consumed abroad. The marked growth of the industry is attributed to the fact that an excellent light is secured at a reasonable rate, wherever gas is available. It is probable that the development of the by-product coke oven is giving an impetus to the business.

The writer desires to acknowledge the courtesy of the Welsbach Co. as extended by Dr. H. S. Miner and Mr. C. E. Bliss during preparation of this article.

World Iron and Steel Output

The National Federation of Iron and Steel Manufacturers of Great Britain has issued a memorandum on the world's output of iron and steel, which contains a statistical survey for several years past. Below are given those figures which have not hitherto been published with those of previous years for purposes of comparison. The production of pig iron and steel in the leading countries was as follows:

FIG IRON PRODUCTION

	1918	1917	1916
United Kingdom, gross tons.....	9,066,000	9,420,000	9,048,000
United States, gross tons.....	39,052,000	38,621,000	39,435,000
Germany, metric tons.....	11,590,000	13,142,000	15,285,000
France, metric tons.....	1,297,000	1,684,000	1,447,000
Total.....	61,005,000	62,867,000	63,215,000

STEEL PRODUCTION

	1918	1917	1916
United Kingdom, gross tons.....	9,591,000	9,840,000	9,196,000
United States, gross tons.....	45,073,000	45,061,000	42,774,000
Germany, metric tons.....	14,874,000	16,387,000	16,183,000
France, metric tons.....	1,912,000	2,232,000	1,952,000
Total.....	71,450,000	73,684,000	70,105,000

The German production for 1918 does not include the output of Luxemburg, the Saar District, and the disannexed Lorraine Province during November and December of that year. The British steel figures include steel castings.

The first and most significant feature of these tables, it is pointed out, is the fall during the war of the output of iron and steel in both France and Germany, the figures in both cases reaching the lowest level in 1918. The United States shows a great increase during the war, while in Great Britain the figures show a fairly

constant output of pig iron and an increased output of steel.

In the case of pig iron the production of these four countries in 1900 amounted to 34,000,000 tons, of which Great Britain produced 9,000,000 tons. In 1913 the total output had risen to 66,000,000 tons, of which Great Britain produced 10,000,000 tons, while in 1918 the total had fallen to 61,000,000 tons, of which Great Britain produced 9,000,000 tons.

The production of iron and steel in countries of the second rank in 1916 and 1917 is given as follows:

	Pig Iron		Steel	
	1917	1916	1917	1916
Austria-Hungary.....	2,418,000	2,921,000	3,330,000	
Canada.....	1,046,000	1,070,000	1,550,000	1,287,000
Italy.....	475,400	467,000	1,304,000	1,269,000
Russia.....		3,738,000		
Sweden.....	829,000	753,000	581,000	614,000
Belgium.....		127,825		95,830

These countries contributed at the outbreak of war about 9,000,000 tons of pig iron and 12,000,000 tons of steel to the world's production. The figures for Italy are significant of the extent to which that country has relied on scrap steel and imported pig iron to obtain steel output.—*Fortnightly Information Review*, Aug. 1, 1919.

How to Relieve "Brass Itch"

The symptoms of brass poisoning and the treatment which should be given are described in the current issue of *Modern Medicine*, Chicago, Illinois, by Dr. R. P. Albaugh, formerly director of the Division of Industrial Hygiene, Ohio State Department of Health.

The symptoms are evident for several hours after exposure to the fumes which are contained in the whitish smoke and sublimation products from molten brass and zinc. The symptoms start with a dry, parched throat, an irritating and unproductive cough, a feeling of constriction in the chest, lassitude, and anorexia, often followed by nausea and vomiting; a headache sometimes develops and chilly sensations are noticeable within one to four hours.

The chills rapidly verge into a distinct rigor which lasts from one and one-half to two or three hours. The application of warm clothing or external heat seems not to diminish the rigor of a chill. Muscular cramps and sharp pains in the joints usually accompany the chill.

The symptoms end rather abruptly, almost by crisis, and are followed at once by a profuse perspiration. The patient will probably fall into a deep sleep following the stage of relaxation and without any apparent ill effects.

Brass poisoning does not occur from handling of the metal or the zinc alloys which go into its composition, but is limited to those exposed to the inhalation of the whitish smoke and sublimation products from the molten metal.

There is no specific treatment for brass poisoning, "brass itch" and "brass chills." Zinc is supposed to be responsible for the bad effects. The affection was formerly confused with malaria.

Some workmen find relief in drinking hot milk to which pepper is added. A good purge also seems beneficial. Dr. Albaugh advises the prevention of brass poisoning by better hygienic arrangements in foundries and smelters, elimination of careless habits of workmen, and large, roomy quarters.

Physical Measurements for Students of Chemistry

Mr. Paul E. Klopsteg of the Leeds & Northrup Co., Philadelphia, presented an appeal in a late number of *Science* for courses in physical measurements for students of chemistry and allied sciences. It appeals to us as sound doctrine, and while the subjects may be included in the curricula of various institutions, we know from experience that an adequate familiarity with them is by far too often lacking among young chemists and Mr. Klopsteg's proposal would seem to cover an important gap.

Although engineering is commonly spoken of as applied physics, the bridge between the pure and applied science in this sense has stretched itself to such amazing lengths that many physicists and many engineers do not attempt to cross it.

Mr. Klopsteg proposes that, in addition to the regular course in general physics, a special course in physical measurements be provided in the senior college year for students who contemplate either graduate work or an immediate entry into industry. He suggests that it occupy at least the equivalent of three 2-hr. periods for one semester of 16 weeks and proposes the following general topics as representing the essential things from which a selection might be made.

(1) The accurate measurement of long and short time intervals.

(2) Measurement of temperatures by methods other than the mercury thermometer. Principles of pyrometry.

(3) Temperature regulation and temperature regulators and controllers.

(4) Principles of precision calorimetry.

(5) The microscope; its theory, and application to the measurement of small lengths.

(6) The reading telescope and its application to the measurement of small angles.

(7) Measurement of refractive index; spectrometer and refractometer.

(8) The spectroscopy, and spectroscopic analysis.

(9) Color and colorimetry; intensity of light and photometry.

(10) The polariscope and polarimeter.

(11) The galvanometer; its use as a deflection and as a null instrument.

(12) Ohm's law; measurement of current and potential differences.

(13) Electric power and heating.

(14) Resistance measurement; Wheatstone's bridge, with application to measurement of electrolytic conductivity. The alternating current galvanometer as applied to conductivity measurements.

(15) The potentiometer; application to measurement of thermo-electric forces, electrode potentials, ionic concentrations.

(16) Electrometers and electroscopes; applications to measurements in radioactivity.

(17) Principles of X-ray measurements.

Personal

Dr. F. C. BROWN has resigned his position as associate professor of physics, University of Iowa, to accept a position as technical assistant to the director of the Bureau of Standards.

Mr. JAMES L. BRUCE has resigned as manager for the Butte & Superior Mining Co. to become general manager for the Davis-Daly Company.

Mr. ALFRED BURTON, who was engaged with the explosives committee of the Imperial Munition Board, Ottawa, Canada, has accepted a position with the Dominion Dyers, Ltd., London, Ontario.

Mr. REX HONEY, formerly connected with the Dominion Forest Products Laboratory, McGill University, Montreal, has been appointed head of the service department of the Abitibi Power & Paper Co., Ltd., Iroquois Falls, Ontario, in charge of efficiency research and raw materials.

Dr. F. M. G. JOHNSON, who has been research chemist for the Canadian Consolidated Rubber Co., Ltd., will again be associated with the chemical department at McGill University, Montreal.

Mr. CHARLES W. MCKAY has recently become associated with the industrial engineering firm of L. V. Estes, Inc., Chicago, Ill.

Dr. C. FERDINAND NELSON has been elected professor of biological chemistry and head of the department of physiological chemistry which has recently been established at the University of Kansas.

Mr. ARTHUR PHILLIPS has been appointed assistant professor of metallurgy in the Sheffield Scientific School, Yale University, New Haven, Conn.

Mr. WARREN C. PROSSER has resigned as superintendent for the Red Mountain Mines Co., to return to professional work in mineral and oil land investigations, with headquarters at Denver.

Dr. J. W. SHIPLEY, professor of chemistry, Manitoba Agricultural College, has resigned to accept an appointment as assistant professor in chemistry, University of Manitoba.

Mr. A. B. SHUTTS has become general manager for the American Ores and Asbestos Co., Globe, Arizona.

Obituary

Mr. FRANK COCHRANE, Minister of Lands, Forests and Mines in the Ontario Legislature, died on Sept. 22 at Ottawa.

Mr. HERBERT G. THOMSON, a graduate of the University of California and general superintendent for the Nevada Packard Mines Co. at Lower Rochester, Nevada, died on Sept. 25 from injuries received in a fall into a shaft while sampling ore.

Mr. HENRY B. UNDERHILL, president of the Selby Smelting & Lead Co., died at his residence in San Francisco on Sept. 14.

Current Market Reports

The Non-Ferrous Metal Market

Tuesday, Oct. 14.—There has been no large transactions in the non-ferrous markets during the past week.

Aluminum.—Transactions are largely made on direct contract between producers and consumers. The open market does not show important activity; 98-99 per cent ingots are quoted at 32-33c. lb.; cast scrap, 24½-25c.; sheet scrap, 23-24c.; and clippings, 26½-27¾c.

Antimony.—On 25-ton lots the price is 8½c. and on broken lots 8¾c. Prices have remained steady in spite of the falling off of the demand by ordnance supply manufacturers. The patent glazed kid leather trade is reported to be using considerable quantities.

Copper.—The close of the war found great supplies of commercial copper alloys such as brass and bronze made up, and

this, in connection with disrupted conditions in Europe, has made the copper market quiet.

Copper, lake.....	22½	— 24
Copper, electrolytic.....	22½	— 23½
Copper sheets, hot rolled.....	35	—
Copper sheets, cold-rolled.....	41½	—

Low brass rods.....	30½	—
Low brass rods & sheets.....	31½	—
Brazed brass tubing.....	39	—
Brazed bronze tubing.....	44½	—
Seamless copper tubing.....	37½	—
Seamless bronze tubing.....	40	—
Scrap, heavy mach. comp.....	17	— 18
Scrap, heavy and wire.....	17	— 18
Scrap, light and bottoms.....	15	— 16
Scrap, heavy, cut and crucible.....	18½	— 19½
Scrap, brass, heavy.....	10	— 11
Scrap, brass, casting.....	12	— 13
Scrap, brass, light.....	10	— 11
Scrap, No. 1 clean brass turnings.....	10	— 11
Scrap, No. 1 comp. turnings.....	15	— 16

Lead.—The price of lead has been advancing and sales are reported as high as 6.3c. The Metal Exchange price is New York spot, 6.15c. and East St. Louis, 6c.

Tin.—The bulk of the present local supply of tin is now tied up in the longshoreman's strike. The market figures are 55 to 56c. lb.

Zinc.—Up to date 3000 tons of zinc have been reported as sold for export. Spot New York quotes 7¾ and East St. Louis 7½c.

Platinum.....	oz.	130.00	—
Silver.....	oz.	1.17½	—

The Iron and Steel Market

There has been very little activity in the iron and steel markets in the past week, the restricting influence being the strike. The mills that are closed are, of course, in no position to sell, as they have large unfilled obligations as it is, while the mills that are operating are called upon for somewhat heavier deliveries than would be the case were there no strike, since many buyers contract with two or more mills, and if one of the mills is closed by strike the buyer furnishes the other with heavier specifications than would be furnished in normal conditions.

The iron and steel strike is now in its fourth week. While operating gains have been made, they have more strategic than tonnage significance, and taking the steel industry as a whole production is at not over about 60 per cent of capacity, or at a rate a few per cent higher than when the strike was at its strongest point, about the middle of the first week.

The present scope of the strike is: Eastern and western Pennsylvania and the South are running full; the Youngstown district has just started; Chicago and Gary are getting about quarter production out, and Johnstown, Buffalo, Wheeling, Mahoning and Cleveland are closed. The large buyers of steel are making practically no effort to supplement their contracts by open market purchases, as the floating supply is altogether too small to count for anything, but occasional or chance buyers are looking around for steel in stock, when the cost of the steel is of small consequence. Even in normal times steel in stock brings much higher than regular mill prices. At this time the jobbers are very reserved in making sales out of stock, and generally speaking are not even supplying their regular customers fully, as their stock would be wiped out promptly if they sold to all applicants.

There has been a moderate amount of activity in pig iron, chiefly for early deliveries, the buyers being consumers whose regular sources of supply were affected by the strike. Foundry iron is a trifle scarcer than before the strike, but basic iron is a trifle more plentiful.

Prices of pig iron and steel products are unchanged.

The Chemical Market

New York, October 16, 1919.

The epidemic of strikes, particularly the steel strike in this country and the strike of transportation workers in England, has imparted its influence to the local chemical market in the form of a shortage in several products, with a resultant higher price. It is further having a tendency to cool interest in contracts. When contracts are offered it is with a protective clause necessitated by the uncertainty regarding future production costs. Demands for heavy chemicals, however, is of such proportions that large quantities are passing into consumption, but the buying is confined in its scope to nearby requirements. Interest in naval stores and vegetable oils is beginning to revive again, but the same is not true of waxes and crude rubber.

HEAVY CHEMICALS

The recent British strike with the unfavorable exchange has worked against export trade and now with all shipping tied up by the present harbor strike, interest centers on domestic commerce. Touching on the export phase, it is of interest that South America continues to place fair sized orders, while last week 1,000 tons of ammonium sulphate were shipped to Spain. During the same period several export inquiries for caustic soda developed, one calling for delivery of 100 tons over the balance of the year.

An increase in price on sodium nitrite, sodium prussiate yellow, formaldehyde, denatured alcohol, gum camphor, fluorspar products, and a cut in figures on sodium bichromate, tartaric acid, and cobalt oxide are the salient developments since the last review.

Sodium nitrite has had a sensational rise, present quotations varying from 15-18c. per lb., in comparison with the recent level of 9¾-10c. Both domestic and English makers are said to be sold up for the balance of the year. Since England has been unable to ship any sodium prussiate, the shortage has become exceedingly acute and prediction has it that it will continue to the end of the year. Speculation has played an active part in the jump to 27c. per lb.

The reasons offered for the new price of 24c. per lb. for formaldehyde set by manufacturers are scarcity, resulting from very heavy buying by France and England, and the increased price of the raw material, wood alcohol. The augmented value of the latter product accounts for the increase of 4c. per gal. on both 188 and 190 proof denatured alcohol, the former thus selling at 56-60c. per gal., the latter at 52-56c., according to quantity. Gum camphor continues to meet with unabated demand and prices are strong at \$3.50-\$3.75. Further competition has lowered sodium bichromate to 12-12½c. per lb. while the new price of tartaric acid in the face of slack demand is 74-74½c. per lb. The decline of 10c. per lb. to \$1.50-\$1.55, on the part of cobalt oxide is due to the domestic article being on the market instead of the Canadian.

Directly affected by the steel strike are aqua ammonia and hydrofluoric acid. With many coke ovens not operating, the production of ammonia and other by-products has decreased. At the same time there has been an unusual call for aqua ammonia. In view of these conditions some apprehension is felt about the supply of other ammonia products, in particular sal ammoniac. Aqua ammonia is firmly held at 8c. per lb. Steel manufacturers have been using little of flux grade of fluorspar, which circumstance has increased production costs of the acid grade. This increase is expressed in an advance of all fluorspar products. The new price named for hydrofluoric acid is 12-14c. per lb., with 15c. per lb. for sodium fluoride, in comparison with 10-11c. and 13-14c., respectively. Sulphuric acid, even in moderate sized quantities, is not to be obtained. Quotations, therefore, are practically nominal. During the war quantities were produced, but upon the signing of the armistice many producers, reasoning that there would be a surplus, ceased its manufacture. At present, one of the leading producers by running his plant to capacity is scarcely able to fill contracts.

COAL-TAR PRODUCTS

Neither unsettled labor conditions nor any other contingency seems able to dampen the demand for coal tar products. While all of these products are becoming scarce, spot aniline oil and aniline salts are unobtainable at the respective prices of 32-33c. and 33-36c. per lb.

Xylol, pure, in tank cars, gal.	.35	—	.45
Xylol, commercial, in tank cars, gal.	.23	—	.27
Xylol, commercial, in tank cars, gal.	.22	—	—

Waxes

Prices based on original packages in large quantities.

Beezwax, natural crude, yellow, lb.	\$0.42	—	\$0.44
Beezwax, refined, yellow, lb.	.46	—	.48
Beezwax, white pure, lb.	.46	—	.48
Carnauba, No. 1, lb.	.85	—	.88
Carnauba, No. 2, regular, lb.	.67	—	.80
Carnauba, No. 3, North Country, lb.	.48	—	.50
Japan, lb.	.18	—	.20
Paraffine wax, crude match wax (white) 105-110 m.p., lb.	.06	—	—
Paraffine wax, crude, acle 124-126 m.p., lb.	.06	—	—
Paraffine wax, refined, 118-120 m.p., lb.	.07	—	.08
Paraffine wax, refined, 128-130 m.p., lb.	.09	—	—
Paraffine wax, refined, 133-135 m.p., lb.	.104	—	.114
Paraffine wax, refined, 135-137 m.p., lb.	.12	—	.13
Stearic acid, single pressed, lb.	.26	—	.28
Stearic acid, double pressed, lb.	.27	—	.29
Stearic acid, triple pressed, lb.	.31	—	.33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940, gal.	\$1.10	—	—
Pine oil, pure, dest. dist., gal.	.96	—	—
Pine tar oil, ref. sp. gr. 1.025-1.035, gal.	.45	—	—
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla., gal.	.34	—	—
Pine tar oil, double ref., sp. gr. 0.965-0.990, gal.	.65	—	—
Pine tar, ref., thin, sp. gr. 1.080-1.090, gal.	.38	—	—
Turpentine, crude, sp. gr. 0.900-0.920, gal.	.85	—	—
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990, gal.	.48	—	—
Pine wood creosote, ref., gal.	.30	—	—

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	\$16.25	—	\$17.50
Rosin E-1, bbl.	280 lb.	17.00	—	19.25
Rosin K-N, bbl.	280 lb.	20.50	—	23.00
Rosin W. G. W. W., bbl.	280 lb.	16.00	—	17.00
Wood rosin, bbl.	280 lb.	16.00	—	17.00
Spirits of turpentine, gal.	1.70	—	—	—
Wood turpentine, steam dist., gal.	1.50	—	—	—
Wood turpentine, dest. dist., gal.	1.48	—	—	—
Pine tar pitch, lb.	100 lb.	8.25	—	8.50
Tar, kiln burned, bbl. (500 lb.), bbl.	13.50	—	—	14.25
Retort tar, bbl., bbl.	280 lb.	14.50	—	14.90
Rosin oil, first run, gal.	1.48	—	—	—
Rosin oil, second run, gal.	.88	—	—	.93
Rosin oil, third run, gal.	.95	—	—	1.07
Rosin oil, fourth run, gal.	1.05	—	—	1.10

Solvents

73-76 deg., steel bbls. (85 lb.), gal.	\$0.334	—	—
70-72 deg., steel bbls. (85 lb.), gal.	.311	—	—
68-70 deg., steel bbls. (85 lb.), gal.	.304	—	—
V. M. and P. naphtha, steel bbls. (85 lb.), gal.	.253	—	—

Crude Rubber

Para—Upriver fine, lb.	\$0.52	—	\$0.52
Upriver coarse, lb.	.51	—	.52
Upriver caucho ball, lb.	.32	—	.32
Plantation—First latex crepe, lb.	.49	—	.50
Ribbed smoked sheets, lb.	.48	—	.49
Brown crepe, thin, clean, lb.	.43	—	.44
Amber crepe thin, clean, lb.	.47	—	.48

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls., lb.	\$0.18	—	\$0.19
Castor oil, AA, 3 in bbls., lb.	.21	—	.22
China wood oil, in bbls., lb.	.22	—	.23
Cocconut oil, Ceylon grade, in bbls., lb.	.173	—	.18
Cocconut oil, Ceylon grade, in bbls., lb.	.19	—	.20
Iron oil, crude, in bbls., lb.	.17	—	.23
Cottonseed oil, crude (f.o.b. mill), lb.	.173	—	.19
Cottonseed oil, summer yellow, lb.	.22	—	.24
Cottonseed oil, winter yellow, lb.	.22	—	.24
Lined oil, raw, car lots, lb.	.65	—	.75
Lined oil, raw, tank cars, gal.	1.65	—	1.70
Lined oil, boiled, car lots, gal.	1.70	—	1.75
Olive oil, commercial, gal.	2.40	—	2.50
Palm, Lagos, lb.	.17	—	.173
Palm, bright red, lb.	.164	—	.173
Palm, Niger, lb.	.16	—	.17
Peanut oil, crude, tank cars (f.o.b. mill), lb.	.23	—	.25
Peanut oil, refined, in bbls., lb.	.23	—	.25
Rapeseed oil, refined in bbls., gal.	1.50	—	1.60
Rapeseed oil, blown, in bbls., gal.	1.57	—	1.70
Soya bean oil (Manchurian), in bbls., N. Y., lb.	.174	—	.18
Soya bean oil, tank cars, f.o.b., Pacific coast, lb.	.141	—	.15

FISH

Winter pressed Menhaden, gal.	\$1.28	—	—
Yellow bleached Menhaden, gal.	1.30	—	\$1.31
White bleached Menhaden, gal.	1.31	—	—
Blown Menhaden, gal.	1.34	—	1.38

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated, ton	\$25.00	—	\$36.00
Barytes, off color, ton	20.00	—	25.00
Blanc fixe, dry, ton	.035	—	.044
Blanc fixe, pulp, ton	35.00	—	47.50
Cascine, lb.	.16	—	.18

Chalk, English, light, lb.	.044	—	.06

Chalk, English, dense, lb.	\$.04	—	\$.05
China clay (Kaolin), imported, lump, ton	25.00	—	35.00
China clay (Kaolin), imported, powdered, ton	30.00	—	60.00
China clay (Kaolin), domestic, lump, ton	10.00	—	20.00
China clay (Kaolin), domestic, powdered, ton	25.00	—	40.00
Fel lapar, ton	12.00	—	16.00
Fluorspar, acid grade, lump, f.o.b. mines, net ton	30.00	—	\$35.00
Fluorspar, acid grade, ground, f.o.b. mines, net ton	35.00	—	45.00
Fuller's earth, domestic, powdered, ton	30.00	—	40.00
Fuller's earth, imported, powdered, ton	—	—	—
Pumice stone, imported, lb.	.03	—	.06
Pumice stone, domestic, lb.	.024	—	—
Shells, T.V., lb.	1.00	—	—
Shells, D. C., lb.	—	—	—
Shells, V. S. O., lb.	—	—	—
Shells, Diamond I., lb.	1.05	—	—
Shells, orange, lb.	1.10	—	1.30
Shells, A.C. garnet, lb.	1.00	—	—
Shells, bleached, bone dry, lb.	1.25	—	—
Shells, bleached, fresh ground, lb.	1.00	—	—
Soapstone, ton	15.00	—	25.00
Talc, domestic, ton	16.00	—	60.00
Talc, imported, ton	55.00	—	60.00

Refractories

Following prices are f.o.b. works:

Chrome brick, net ton	80-90 at Chester, Penn.
Chrome cement, net ton	45-50 at Chester, Penn.
Clay brick, lat quality freelay, net ton	35-45 at Clearfield, Penn.
Clay brick, 2nd quality, net ton	30-35 at Clearfield, Penn.
Magnesite, dead burned, net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2 in., net ton	80-90 at Chester, Penn.
Silica brick, net ton	41-45 at Mt. Union, Penn.

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y., net ton	\$200.00	—	\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon, lb.	.25	—	.40
Ferro-chrome, 6-8% Cr. contained, 2-4% carbon, lb.	.70	—	—
Ferro-manganese, 70-80% Mn., gross ton	105.00	—	115.00
Spiegel, 16-20% Mn., gross ton	35.00	—	40.00
Ferro-nickel, 50% Ni., gross ton	85.00	—	90.00
Ferro-silicon, 75% Si., gross ton	150.00	—	175.00
Ferro-silicon, 10-15% Si., gross ton	30.00	—	35.00
Ferro-tungsten, 70-80% W., lb.	1.25	—	1.40
Ferro-uranium, 35-50% of U., lb.	7.00	—	—
Ferro-vanadium, 30-40% per lb. of contained V., lb.	5.50	—	7.00

Ores and Semi-finished Products

Chrome ore, 35-40% Cr. O ₂ , unit	\$0.60	—	\$0.80
Chrome ore, 48% of Cr. O ₂ , unit	1.00	—	1.00
Coke, foundry, f.o.b. ovens, net ton	5.50	—	6.00
Coke, furnace, f.o.b. ovens, net ton	4.00	—	5.00
Petroleum coke, refinery, Atlantic seaboard, net ton	12.00	—	12.50
Fluorspar, gravel, f.o.b. mines, net ton	20.00	—	25.00
Manganese ore, chemical (MnO ₂), unit	.50	—	.75
Molybdenum, 85% MoS ₃ , per lb. of MoS ₃ , lb.	.75	—	.85
Tungsten, Scheelite, 60% W ₂ O ₅ and over, per unit of W ₂ O ₅ , unit	9.00	—	15.00
Tungsten, Wolframite, 60% W ₂ O ₅ and over, per unit of W ₂ O ₅ , unit	7.50	—	10.00
Uranium oxide, 96%, lb.	1.00	—	—
Vanadium pentoxide, 99%, lb.	6.00	—	—
Pyrites, foreign, lump, unit	.13	—	—
Pyrites, foreign, fine, unit	.13	—	—
Pyrites, domestic, fine, unit	.13	—	1.74
Ilmenite, 52% TiO ₂ , f.o.b. N. Y., net ton	40.00	—	—
Rutile, 95% TiO ₂ , f.o.b. N. Y., net ton	200.00	—	—
Carnotite, minimum 2% U ₂ O ₈ , per lb. of U ₂ O ₈ , lb.	2.75	—	3.00
Zircon, washed, iron free, f.o.b. N. Y., net ton	13.00	—	—
Monazite, per unit of ThO ₂ , f.o.b. N. Y., unit	42.00	—	—

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags, bbl.	\$2.30	—	—
Lump lime, common, including container, 300 bbl.	2.65	—	—
Common brick, at dock, M.	15.00	—	—
Yellow pine, 3x4 to 8x8, 20 ft. and under, M.	48.00	—	—
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago, M.	55.00	—	—
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis, M.	43.00	—	—
Roofing, tar felt (14 lb. per 100 sq. ft.), ton	60.00	—	70.00
Roofing, tar pitch (in 400-lb. bbl.) carlots, ton	20.00	—	—
Roofing, asphalt pitch carlots, ton	34.00	—	—
Roofing, asphalt felt carlots, ton	63.00	—	—
Roofing, slate-surfaced, per roll of 108 sq. ft. carlots, ton	2.25	—	—
Roofing, slate-surfaced shingles, 100 sq. ft. carlots, gal.	6.00	—	—
Lined oil, raw in barrels, gal.	2.15	—	—
Lined oil, 5 gal. cans, gal.	2.30	—	—
Red lead, dry, 100 lb. keg, lb.	1.15	—	—
Red lead, in oil, 100 lb. keg, lb.	1.41	—	—
Red lead, 5 lb. cans, lb.	1.15	—	—
Red lead, in oil, 5 lb. cans, lb.	1.64	—	—
White lead, dry and in oil, 100 lb. keg, lb.	1.15	—	—
White lead, dry and in oil, 25 and 50 lb. kegs, lb.	1.15	—	—
White lead, dry and in oil, 5 lb. cans, lb.	1.15	—	—

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in., 100 lb.	\$2.45	—	—
Angles, 3 to 6-in., 4-in. thick, 100 lb.	2.45	—	—
Tea, 3-in. and larger, 100 lb.	2.45	—	—
Plates, 100 lb.	2.66	—	—
Rivets, structural, 1-in. and under, 4.20	—	—	—
Rivets, conchard for boilers, 4-in. and larger, 100 lb.	4.30	—	—
Sheets, No. 28 black, 100 lb.	4.35	—	—
Sheets, No. 10 blue annealed, 100 lb.	4.55	—	—
Sheets, No. 28 galvanized, 100 lb.	5.70	—	—
For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.	—	—	—

INDUSTRIAL

Financial, Construction and Manufacturers' News

CONSTRUCTION AND OPERATION

Note: These items were compiled as of Nov. 5, but appear in this issue due to the delay in publication caused by the printers' strike.

Arizona

DOUGLAS—The North Tigre Mining Co. is in the market for new machinery for a 100-ton concentration mill. Frank J. Holmes, Superintendent.

CLIFTON—F. R. Shortridge, town clerk, will receive bids until Oct. 29 for the construction of a complete sewerage system, including a 20x28-ft. Imhoff tank, etc. Olmsted & Gillette, 1112 Hollingsworth Bldg., Los Angeles, consulting engineers, A. J. Kerr, town engineer. Noted April 15.

California

AVON (Associated P. O.)—The Associated Oil Co., Sharon Bldg., San Francisco, will build a group of buildings for an oil refinery, to include tanks, stills, pipe lines, etc. Estimated cost, \$2,000,000.

SAN DIEGO—The Bureau of Yards & Docks, Navy Department, Washington, D. C., is having plans prepared for the construction of a surgical laboratory in connection with the proposed hospital at Balboa Park. Estimated cost, \$2,000,000. P. W. Southworth, engineer.

SAN FRANCISCO—The U. S. Rubber Co., 336 2nd St., received bids for the construction of an addition to its rubber plant, from William Martin, 150 Jessie St., \$53,900, and D. B. Farquharson, 1760 Ellis St., \$57,500.

Connecticut

EAST HARTFORD—The town will soon receive bids for the construction of a reservoir dam, chlorinating plants and pipe lines. Estimated cost, \$300,000. C. H. Olmstead, town engineer.

District of Columbia

WASHINGTON—J. A. Cullen, Cavendish Apartments, wishes to lease a small chemical plant with the privilege of purchasing. He prefers one with a crusher and ball mill, to be located in the eastern section of the country and have good transportation facilities. He also wishes to buy sheet lead, rectangular crystallizing vats, and proof pumps, motors, pulleys, shafting, etc.

Florida

TALLAHASSEE—The city plans to construct gas and water plants, also install machinery in same. Estimated cost, \$65,000.

Illinois

CHICAGO—The Dallas Brass & Copper Co., 225 North Jefferson St., has awarded the contract for the construction of a 5-story, 100x200-ft. factory, on Orleans St. and Institute Pl., to G. Thompson & Son, 30 North LaSalle St. Estimated cost, \$300,000.

Kansas

ELK CITY—The city has awarded the contract for the construction of a water system and a filtration plant, to Johnson, Morris & Hill, Independence, at \$21,300. Noted Sept. 25.

Maryland

BALTIMORE—J. H. Cottman & Co., 812 Keyser Bldg., has awarded the contract for the construction of a 1-story, 40x140-ft. chemical factory, on Columbia Ave. and Beaver St., to Richard Morton, 812 Equitable Bldg. Estimated cost, \$15,000.

Massachusetts

WOBURN—The Louis Foucar Co., manufacturer of leather, plans to rebuild its factory which was recently destroyed by fire. Estimated cost, \$60,000.

Minnesota

ST. PAUL—J. W. Stevens, architect, Exchange Bank Bldg., is receiving bids for the construction of a 4-story, 62x98-ft. paint factory on University Ave., for the Mutual Paint Co., Exchange Bank Bldg. Estimated cost, \$80,000.

Missouri

NICK CITY—Smith & Co. is having the old mill on Reliance ground remodeled and is in the market for 1 set of rolls and 3 tables. J. E. Smith, manager.

ST. LOUIS—The Mineral Refining & Chemical Corporation, Iron Mountain tracks and River Bed Peres, plans to construct a chemical plant, and is in the market for chemical manufacturing equipment. Estimated cost, \$4,000,000.

ST. LOUIS—The St. Louis Brass Manufacturing Co., Washington and Jefferson Aves., has awarded the contract for the construction of a 5-story, 80x110-ft. factory, at 2600 Washington Ave., to the James Black Construction Co., Wright Bldg. Estimated cost, \$500,000. Noted Sept. 14.

Nevada

LUNNING—The United Lodi Mines Co. plans to construct a hoist compressor, concentration and cyanide plant in connection with its silver and lead mine at Lodi. The company is in the market for concentrators \$25,000. Homer Wilson, general manager.

New York

ALBANY—Witherbee, Sherman & Co., 2 Rector St., are having plans prepared for the construction of a 1-story fertilizer plant on Westerlo Isle. Estimated cost, \$1,000,000.

DEXTER—The Dexter Sulphite Pulp & Paper Co. plans to construct a plant for the reclamation of commercial alcohol from waste black liquor in sulphite pulp process. Estimated cost, \$300,000. Address, H. O. Long, Care of company.

GENEVA—The Geneva Limestone Co. plans to install two 42x48-ft. jaw crushers and transmission for same. C. Hutchins, manager.

MEDINA—The Niagara Sprayer Co. has purchased a site on Telegraph Rd., and plans to build a chemical manufacturing plant on same, for the manufacture of calcium arsenate.

STATEN ISLAND—The Construction Division of the War Department, Washington, D. C., will soon receive bids for the construction of a photographic laboratory, etc., in connection with the proposed Aerial Defense Station. Estimated cost, \$1,000,000.

ROCHESTER—The H. E. Mole Manufacturing Co. plans to construct a tile and brick laboratory on Burrows St., and is in the market for laboratory equipment. Estimated cost, \$12,000.

North Carolina

ENFIELD—The city plans to complete the waterworks and sewerage systems. Estimated cost, \$25,000. J. B. McCrary Co., Third National Bank Bldg., Atlanta, Ga., engineer.

FRANKLINTON—The Mayor will soon award the contract for installing water and sewerage systems, to include a sewage disposal plant, etc. Estimated cost, \$40,000. Gilbert C. White, Durham, engineer.

North Dakota

MINOT—The city voted \$280,000 bonds for the construction of a sewage disposal plant. Project includes Imhoff tank, trickling filters, etc. E. J. Thomas, engineer. Noted Sept. 14.

Ohio

CLEVELAND—The Metals Plating Works, 7019 Cleveland Ave., has awarded the contract for the construction of a 1-story, 34x90-ft. factory, at 9607 Quincy Ave., to W. F. Hyde Co., 1008 Scoville Ave. Estimated cost, \$10,000.

CLEVELAND—The Ultimate Tire & Rubber Co., Hippodrome Bldg., is having plans prepared for the construction of a 2-story, 100x250-ft. rubber factory, on East 152nd St. Estimated cost, \$200,000. W. S. Ferguson, 1900 Euclid Ave., engineer.

NORWOOD—The city plans to install a water softening system in connection with the proposed waterworks. Estimated cost, \$50,000. Allen Kisinger, city engineer.

Oklahoma

ADA—The city is having plans prepared for the construction of a sewage disposal plant. Johnson & Benham, Firestone Bldg., Kansas City, Mo., consulting engineers.

GARDER—The city has awarded the contract for the construction of a sewerage system to include a disposal plant, to L. A. Gallier, 1509 West Cherokee Ave., Enid. Estimated cost, \$51,048.

HARTSHORNE—The city will soon award the contract for the construction of a gravity type rapid sand mechanical filter plant, clear well coagulating basin, pipe gallery, etc. Estimated cost, \$35,000. V. V. Lott & Co., 605 Capital Bldg., engineers. Noted Aug. 15.

HENRVETTA—Albert Rowing plans to construct a 2-story, 70x160 ft. glass factory on Main St. Estimated cost, \$75,000.

MILL CREEK—The Miller Worley Tailing Mill Co., Tar River, is having the old Schultz mill moved from Lincolnville to Tar River to operate the Croesus tailings and is in the market for a gas engine and 3 tables. W. C. Miller, superintendent.

PICHER—The Cortez Mining Co. is having the old True Blue mill moved from Quapaw and will erect it on Commonwealth lease, here. The company is in the market for a compressor, 2 sets of rolls, hoist and 2 tables. M. Lichter, superintendent.

PICHER—The St. Regis Mining & Smelting Co. is having its old mill moved from Joplin to near least-hill and is in the market for pig irons, 3 tables, etc. T. Shelton, superintendent.

TAR RIVER—The Oklahoma Woodchuck Zinc & Lead Co. is building a flotation plant for zinc and lead minerals, and is in the market for 1 rougher and 1 cleaner flotation machine. Oscar Bailey, superintendent.

Pennsylvania

PORT KENNEDY—The Valley Forge Magazine Co. plans to construct a 1-story, 35x127 and 32x177-ft. factory. Work will be done by day labor.

Rhode Island

CENTERVILLE—The Warwick Mills have awarded the contract for the construction of sand filter beds, etc., to J. McCusker, Phenix. Estimated cost, \$35,000.

Texas

GORMAN—The city has awarded the contract for the installation of a sanitary sewer and disposal plant, to the Winslett-Eldredge Co., 1001 Main St., Dallas, at about \$159,000.

West Virginia

MARTINSBURG—The city has awarded the contract for the construction of a sewage disposal plant, to the Cox Construction & Lumber Co., Martinsburg, at \$48,561. Noted May 15.

Wisconsin

MILWAUKEE—J. W. Ellms, engineer, 1263 Cooke Ave., Cleveland, Ohio, will complete experiments about Feb. 1, for construction of a filtration plant and will submit same to City Council for its action. Estimated cost between \$4,000,000 and \$5,000,000.

RACINE—Alvord & Burdick, engineers, 8 South Dearborn St., Chicago, are preparing plans for the construction of a filtration plant, the enlargement of the storage plant and extension of distribution facilities, in connection with the municipal waterworks here.

Ontario

NIAGARA FALLS—C. M. Boster, architect, 102 Main St., will soon award the contract for the construction of a 2-story College Institute for the High School Board. Chemical and physical laboratory equipment will be installed in same. Estimated cost, \$100,000.

FORD CITY—The Separate School Board has awarded the contract for the construction of a 2-story school, to Wells & Gray, Confederation Life Bldg., Toronto. A physical and chemical laboratory will be installed in same. Estimated cost, \$140,000.

COMING MEETINGS AND EVENTS

THE AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition of gas appliances and apparatus at the Hotel Pennsylvania, New York, Oct. 13 to 18.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its sixteenth general meeting at the Hotel Commodore, New York, Oct. 24 and 25.

THE SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall convention Oct. 29 to 31 inclusive, at Cleveland, Ohio.

INTERNATIONAL TRADE CONFERENCE has been called by the Chamber of Commerce of the United States for the week of Oct. 29 at Atlantic City. The International Trade Conference tour starts Oct. 17 and will continue until Nov. 28, 1919.

Industrial Notes

THE CALKINS CO., Los Angeles, announces the removal of the company's sales rooms and offices to larger quarters at 934 South Main St., Los Angeles. Mr. H. J. Parsons, the manager, reports an exceptional demand for laboratory equipment and chemicals.

THE RICHARDSON-PHENIX CO. announces the appointment of Mr. L. E. Strohman as vice-president and general manager, and Mr. J. William Peterson as president and treasurer.

THE HOLMES ADVERTISING SERVICE, Pittsburgh, Pa., reports that William H. Harris, district representative of the Colonial Supply Co., has removed his offices from the Federal Bldg. to 507 Stambaugh Bldg., Youngstown, Ohio.

HAMILTON & HANSELL, Inc., New York City, announces that the name of the firm has been changed to the American Transmarine Company, Inc.

THE CANADIAN WESTINGHOUSE CO., LTD., Hamilton, Ont., announces that Mr. N. S. Braden, formerly sales manager, has been elected vice-president, and Mr. H. M. Bennett, formerly assistant sales manager, has been appointed sales manager.

THE WESTERN RESEARCH CO., Denver, Colo., has issued a booklet covering data on the corporation, the organization, financial, laboratory departments, samples for testing laboratory tests, mechanical and chemical tests, charges, oil flotation tests, investigation of oil shales, density and hardness of materials, equivalents of the Baumé scale and specific gravity of oils, mineral deposits, non-metallic minerals and miscellaneous non-metallic minerals.

THE WESTINGHOUSE ELECTRIC & MFG. CO. announces that Mr. Arthur B. Reynolds, formerly director of the East Division at Pittsburgh, has recently been made works manager of the East Springfield plant.

The objects of the PAN-AMERICAN SOCIETY OF THE UNITED STATES as set forth in its charter are:

1. To promote acquaintance among representative men of the United States and those of the other republics of America.
2. To show hospitality and attention to representative men of the other republics of America who visit the United States.
3. To take such other steps, involving no political policy, as the society may deem wise to develop and conserve mutual knowledge and understanding and true friendship among the American republics and peoples.

As a step toward the realization of these aims the society has undertaken a publication, which is designed both to keep its members in touch with what the society is doing and to acquaint them with what is going on in our sister republics. The Review will contain the following: Personal information with information on government, legal, and commercial subjects and the editor will be glad to receive any matter coming within those categories. The Pan-American Review is, in other words, a "step," not involving any "political policy," but intended "to develop and conserve mutual knowledge and understanding and true friendship among the American republics and peoples." The Pan-American Society can be addressed at 15 Broad St., New York City.

MR. CHARLES P. MADSEN has removed his laboratory from 14 Walnut St., Newark, N. J., to 33 East 17th Street, New York City, where he has more extensive facilities for investigation and demonstration of electrolytic and other processes.

THE GOULDS MFG. CO. of Seneca Falls, N. Y., has opened a district sales office, Detroit, Mich., in the Dime Bank Bldg., which is in charge of Mr. E. B. Gould.

THE NORTON CO. and the NORTON GRINDING CO. are now being conducted by the Norton Company with the following board of directors: George I. Alden, chairman of the board; Mr. Charles L. Allen, president and general manager; Mr. Alhus C. Higgins, treasurer and general counsel; Mr. George N. Jeppson, secretary and works manager; R. Sanford Riley and John Jeppson.

TAGGART & YERXA, a new partnership, has opened a testing and analytical laboratory at 165 Division St., New York City. It is prepared to act as consultant on the operation or design of plants for the treatment of ores and metal plant wastes and for crushing and handling rocks.

THE SMITH CHEMICAL & COLOR CO., Inc., importer, exporter, and manufacturer of chemicals and colors, with main offices located at 116 Nassau St., New York City, has

been formed. Mr. Casper Smith, organizer of this company and its president, will be the active operating head of this new organization. He was the director of sales for the Katzenbach & Bullock Co. until recently, when he resigned to organize the new company.

THE HERCULES ENGINEERING CORP. announces the creation of a new department for the design and construction of the special equipment necessary for the general design and handling of all commercial gases. This department will be under the direction of Mr. Richard Neuhaus, for many years in technical charge of plant operation for the Electro-Blanching Gas Co., Niagara Falls, N. Y.

THE CELITE PRODUCTS CO. has appointed Mr. Charles P. Derleth as its St. Louis representative. This company is to be represented in the Bronx, Brooklyn and Long Island districts of New York by Mr. Vincent A. Lambaise, who for several years past has been active in sale promotion of Sil-O-Cel and Filter-Cel.

THE JEFFREY MFG. CO., Columbus, Ohio, has opened a new branch office at the Book Bldg., Detroit, with Mr. O. B. Wescott in charge.

THE LAKEWOOD ENGINEERING CO., Cleveland, Ohio, calls attention to a bulletin, Vol. 1, No. 1, on its products which was dropped in the mail in August. It is a directory of fight with Lieut. Comey from Dayton to Cleveland.

L. V. ESTES, INC., announces that Mr. Charles W. McKay has taken charge of its appraisal division. This division specializes in the appraisal of real estate for purposes for Federal income tax purposes and in the appraisal of public utility properties in connection with rate cases.

THE AMERICAN STEAM CONVEYOR CO. announces the promotion of Thomas O. Morgan to regional director of the central department of the New York office to the position of sales engineer for Long Island and Connecticut territory. The office of J. S. Valentin, regional engineer in charge of the Philadelphia territory, has been established in the North American Bldg.

THE UNITED FILTERS CORP. announces a line of filter presses of the plate-and-frame and recesses types which are known as "United." This places the corporation in a position to furnish the three types of filters in general use—the pressure-leaf type, represented by the Kelly and Sweetland filters, the continuous type represented by the American filter, and the plate type, known as the "United." It will also enable it to offer the most appropriate type of filter for different kinds of work. Bull. No. 50 illustrates the new presses.

THE FALCON STEEL CO. is erecting a new sheet mill at Niles, Ohio, with eight stands of electrically driven rolls, which is to be of the most modern type. Powdered coal will be applied to the sheet in the furnaces as well as a slabbing furnace, two double box double chamber annealing furnaces, three galvanizing kettles and power plant boilers. A blue annealing furnace will be included in the furnace equipment. The initial installation of coal-preparing apparatus will consist of a complete 5-ton coal pulverizing plant, including the necessary coal crusher, elevators, crushed coal bin, Ruggles-Coles drier and Raymond mill, together with the powdered coal hoppers for feeding power rolls, the furnaces, pulverized coal feeders, burners, and the pulverized coal will be transported from the milling plant through standard 4-in. wrought pipes to storage bins in the power plant. The mill is under construction by the compressed Air System. Contract for the complete fuel equipment has been awarded the Quigley Furnace Specialists Co., New York City. It is anticipated that this mill will be in operation by Jan. 1.

DANTZIG, PFEIFFER & RITT announce the formation of this firm of consulting mathematicians, with offices at 500 West 116th St., New York City. This firm undertakes to handle all problems arising in industry for the solution of which the knowledge of a mathematical specialist may be necessary. Each of the members of the firm has been privately engaged for some time in work of this nature, in addition to his other professional activities, and it was at the suggestion of clients that the decision was made to set up a consulting partnership which would extend to the industrial world the resources of modern pure and applied mathematics. Dr. Dantzig is a graduate of the University of Paris and of the Ecole Supérieure d'Aéronautique et de Construction Mécanique. He has taught at Indiana University and at Columbia. During the

war he was in charge of the mathematical work of the instrument section of the U. S. Ordnance. Dr. Pfeiffer received the degree of mechanical engineer from the Stevens Institute of Technology and the degree of Doctor of Philosophy from Columbia University. He has taught mathematics at Harvard, Princeton, and Columbia. He is an associate editor of the Annals of Mathematics. Dr. Ritt took the degree of Ph.D. at Columbia University. He was for three years at the Naval Observatory and has since taught mathematics at Columbia. During the war he was one of the chief ballisticians in the U. S. Ordnance.

Manufacturers' Catalogs

A. P. MUNNING & Co., Chicago, Ill., has issued Bull. 1000 on buffing and polishing compositions.

THE ALLIS-CHALMERS MANUFACTURING CO., Milwaukee, Wis., calls attention to Bull. No. 1096-A, dated March, 1919, on Direct Current Motors and Generators, Types "K" and "K2," Bulletin 558, dated June, 1919, entitled "Forgings."

New Publications

NEW UNITED STATES TARIFF COMMISSION PUBLICATIONS: Information Concerning Zinc Ore; Information Concerning the Pyrites and Sulphur Industry; Information Concerning the Potash Industry; Information Concerning Optical Glass and Chemical Glassware; Information Concerning Manganese Ore; Census of Dyes and Coal-Tar Chemicals, 1918; Information Concerning Tungsten-Bearing Ores; Information Concerning Magnesite Industry. With the exception of the last two publications were printed for use of the Committee on Ways and Means, House of Representatives.

UNITED STATES COUNCIL OF NATIONAL DEFENSE: A Glimpse and a Look Into the Future, by Grosvenor; The Cause of the Future of the Council; An Analysis of the High Cost of Living Problem, submitted by the Director of the Council to the Hon. W. D. Baker, Secretary of War; The United States Council of National Defense, by Emily Newell Blair.

NEW BUREAU OF STANDARDS PUBLICATIONS: Scientific Paper No. 337, Constitution and Metallurgy of Aluminum and Its Light Alloys With Copper and With Magnesium, by Paul D. Merica, R. G. Waterberg and J. R. Freeman; Tech. Paper No. 121, Strength and Other Properties of Wrought Iron and Steel, by W. C. Bragg; Tech. Paper No. 123, Physical and Chemical Tests on the Commercial Marbles of the United States, by D. W. Kessler; Paper No. 129, Notes on the Graphical Representation of White Cast Iron Upon Annealing, by Paul D. Merica and Louis J. Gurevich; Tech. Paper No. 116, Silica Refractories, Resources, Properties, Their Quality and Methods of Testing the Raw Materials and Finished Ware, by Donald W. Ross; Tech. Paper No. 136, Determination of Free Carbon in Rubber Goods, by A. H. Smith and S. W. Epstein.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 176, Recent Developments in the Absorption Process for Recovering Gasoline From Natural Gas, by W. P. Dykema; Bull. 178-A, Water Gases, by Van H. Munnick; Bull. 178-B, Cyanide Solutions, by Van H. Munnick; Tech. Paper 212, The Determination of Combustible Matter in Silicate and Carbonate Rocks, by A. S. Eldred, W. C. Bragg and G. B. Treadwell; Bull. 178-C, Electrodeposition of Gold and Silver From Cyanide Solutions, by S. B. Christy; Bull. 178-B, W. Minerals Nitrogen Fixation and Sodium Cyanide, by Van H. Munnick; Investigator Series No. 18, Zinc Industry in Belgium, by March F. Chase; Present Conditions in the Wisconsin Zinc District, by F. B. Hyder.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: Preliminary Report on the Mineral Resources of the United States, Part I, Introduction by Edson S. Bastin, statistics assembled by Martha B. Clark and data furnished by specialists of the Division of Mineral Resources. Resources published Aug. 1919, 1124. Prices of Coal and Coke 1913-1918, by C. E. Leshner (Mineral Resources of the U. S., 1918, Part II), published Aug. 29, 1919; H-31, Potash and Soda, by J. D. Northrop (Mineral Resources of the U. S., 1917, Part II), published Aug. 4, 1919; I-A, Mineral Production of the United States in 1916, Introduction by J. D. Caskey. Summary by Martha B. Clark (Mineral Resources of the U. S., 1916, Part II), published June 28, 1919.

An Unscrambled Organization

AT VARIOUS times within the past two months the Editor has tried to keep the friends of CHEMICAL & METALLURGICAL ENGINEERING in touch with the unfortunate situation arising from the pressmen's strike. For a month no effort was made to resume publication; then when active measures were taken to print despite the radicals the problem of "unscrambling" our highly organized departments would knit the brows of a Standard Oil lawyer. Our readers cannot perhaps appreciate the almost insurmountable difficulties which on the surface appear only as a rather erratic date of issue. Although held by the Post Office to consecutive page numbering and to back-dating the issue, it is important to note that the news pages in each issue are made up but a few days before it reaches your hand.

A Scotch Professor and The Control of Research

IN AN address before the Mathematical and Physical Science Section of the British Association for the Advancement of Science, at its recent Bournemouth meeting, Professor A. GRAY spoke his mind with some fervor in regard to several things, but first about the lack of scientific training among men in authority and influence. Among the instances in which he found crass ignorance in place of the anticipated open minds, he mentioned the following: A very eminent lawyer declared that one of NEWTON's laws of motion was that "friction is the cause of oscillations." In a discussion on the Forestry bill in the House of Lords a member of that noble body asserted that forestry had nothing to do with science; all that was needed was to dig holes and stick young trees into them. Of the committee which is to manage and foster the dye industry of Great Britain the supermen in control have refused to allow any man of scientific eminence to become a member—and this in spite of remonstrance. He heard a leading statesman assert that an electrical efficiency of 98 per cent might, by progress of electrical science, be increased fourfold.

This sounds almost familiar. It would not be hard to find American instances to match them. It does

beat all how unashamed men are of ignorance of science, while almost anyone would blush to be unfamiliar of the legend of the heel of ACHILLES.

These instances were given by way of introduction to the Scottish professor's comments on centralization of scientific effort, and his doubts as to the unailing wisdom of a High Commission sitting in London to direct it. He held direction by a central body in London to be warranted for work for which the funds may be obtained in London, but he protested that local incentives are not easily moved. He could not see the wisdom of giving charge of special research scholarships in all English and Scottish universities to a metropolitan bureau. "I observed," he added, "with some amazement, that, according to the proposals of one committee for applied science, which is prepared to give grants and premiums for researches and results, the professor or head of the department from whom will generally come what are most important, the ideas, is to have no payment—and the results are to be the property of the Committee!"

He fears too much control of research. He calls to mind the tremendous series of results in electricity of which the beginning was FARADAY's and HENRY's work on the induction of currents, and the conclusion which was the work of HERZ on electric waves. He doubts if these men would have received grants for their work from a body of good business men, and yet they were the pioneers of industry. He made an earnest plea for independence of research, especially in pure science, on the ground that control defeats its own purpose.

We have great confidence in the research organizations that have been established in this country, the need of which was made manifest by the war. But we think it well to bear in mind the hazards of centralization. Many of us can recall the launching of trusts in business fifteen or twenty years ago, and the cheerful hopes which were entertained that, by central control, the elimination of unnecessary sales forces, and the specialization of work, the optimistic and vast body of mortals let in on the ground floor of each establishment were to grow rich. Those were days of glorious dreams—but only a few of them came true.

The head of a research organization must be easy and gentle and kindly, lest he destroy initiative.

Initiative is as evanescent as good will, and at the first sign of bumptiousness or vanity or offensiveness it flies out of the window. System and order and economy are all excellent in their way, but in research the most needful thing is the right man at the head.

Lessons From the Industrial Conference

RAISSING a point of order on the hour of adjournment saved the President's Industrial Conference from disintegration twice during the second week of its deliberations at Washington. The steel strike resolution introduced by the Labor Group, calling on the Conference to appoint six of its members to adjudicate the strike, proved to be the rock on which the assembly was almost shipwrecked. And a wreck surely would have ensued if the Labor sponsors of the resolution had allowed the Conference to vote on the measure. Instead, they resorted to the rules and forced adjournment because the agreed hour had been reached and passed, just as a vote was about to be taken.

But the remainder of the week was not turned to any better advantage. Instead of following the sound advice of JOHN SPARGO—that the Conference should first receive all the resolutions to be offered, then classify them, and finally proceed to their consideration in an orderly manner—it was decided to abandon temporarily any consideration of the steel strike resolution, and to direct the General Committee to bring in within 24 hours a proposal on the vital subject of collective bargaining! Obviously this was a difficult task, because the Conference had not even considered the subject in debate.

The result was that a resolution evolved under strain and pressure was brought in and debated for several days without effect. And after one or two substitutes had been offered, and a parliamentary situation created thereby, a vote was about to be reached when the rules were again invoked to force adjournment. The vote plainly would have defeated the measure and the Conference would have gone to pieces. Thus twice in one week parliamentary tactics prevented disintegration!

It is now quite evident that if any Conference is to accomplish the purpose for which it was called, a different procedure will have to be adopted. There are certain fundamental questions in industrial relations that all of the population must agree upon if possible. These fundamentals comprise a platform which industry would welcome for its guidance. It is useless to quibble over details and particulars as long as fundamental principles are unstated, and it is to be hoped that new tactics will be adopted.

There are many plans for industrial representation or industrial democracy in existence and operation throughout the country. These should be studied and published. Some harmonious pronouncement should be sought on such subjects as production, wages, hours

of labor, women and children in industry, collective bargaining, mediation and arbitration, the role of management, provision against unemployment, industrial conference boards, open and closed shops, the conduct of strikes and lockouts, the nature of public and private service, training of workers, and other phases of industrial relations. If the new Conference can do something of this kind the country will look to it for guidance and untold good can come from its deliberations. Nothing short of this can be considered a satisfactory outcome. And nothing short of this will be effective in clearing the national thought on our industrial situation, and enable the country to combat successfully the economic fallacies that are being preached by the radicals.

A New Function for Our Engineers Abroad

IN YEARS gone by the usefulness of an engineer in backward portions of the earth possessing great natural resources was limited to a large extent. Whatever his former familiarity with most modern mechanical equipment and his natural prepossessions in its favor, he soon found when figuring his own specific problems that owing to the extremely low cost of human labor it was impossible to effect any money saving by the use of even the most highly developed mechanical appliances—often they would hardly be able to compete with hand labor in net operating expense, without allowing anything for capital charges and depreciation. This was particularly true about the handling of materials. Laborers were hired from the surrounding country, they brought along their own horses and carts—and the whole problem of getting huge quantities of materials from one place to another was solved, and at a price which would make a steam shovel contractor with his automatic dump cars envious.

Consequently, the engineer soon found that his function was largely the management of a concern run by man-power rather than the designing of labor-saving methods of doing the work. Labor was too cheap to save!

But revolutionary conditions in northern Europe and Asia, at least, have changed all this. As pointed out recently by ROBERT S. BOTSFORD, an American mining engineer just returned from Petrograd after seven years in Russia and Siberia, labor costs have risen to ten times their former level, what with increased wages and decreased willingness. It is therefore obvious that a revolutionary change has come over the relation between mechanical equipment and "main strength and awkwardness," and with this new relation appears a change in the proper status of the engineer. It is certain that there is to be a tremendous demand from established industries in these regions, as soon as their governments are stabilized and can inspire confidence, not only for labor-saving machinery, but also for brains to install it to best advantage and keep it running after it is installed.

Readers' Views and Comments

Sulphuric Acid Nomenclature

To the Editor of Chemical & Metallurgical Engineering

SIR:—I quote a few sentences from the article "Calculation of Hydrometer Degrees, Gravities and Weights With the Slide Rule," by Wallace Savage, appearing in your Sept. 15 issue:

"Without doubt there is much virtue in the simple integer 'degree' scales. For instance, take 66 deg. Baumé oil of vitriol. Who would prefer to memorize 1.8354 sp.gr. or try to teach it to acid plant workmen? No doubt the per cent hydrometer is the instrument of the future. However, some substances such as sulphuric acid do not lend themselves well to this type of instrument."

I agree that sulphuric acid with its present general use of all terms of its nomenclature would not lend itself well towards this type of instrument. But why not use one general per cent term, thus making it more possible and practical to use it?

Going back to the nomenclature, we have all strengths up to 93.19 per cent H_2SO_4 termed as so many degrees Baumé. The term oil of vitriol is often misquoted in that it refers to 66 deg. acid only. From 93.19 per cent to 100 per cent H_2SO_4 acid is termed as so many per cent in terms of H_2SO_4 . From 100 per cent on we have fuming sulphuric or oleum. Here we have more confusion. As a specific case take 20 per cent fuming or oleum. This strength has an actual H_2SO_4 content of 80 per cent and is generally referred to as 20 per cent, 85.3 per cent or 104.5 per cent. Twenty per cent is the per cent of free or uncombined SO_3 , 85.3 the total per cent SO_3 and 104.5 the equivalent per cent 100 per cent H_2SO_4 it would produce if sufficient water were added to combine with all of the free or uncombined SO_3 .

Why all of this confusion in terms? If anyone doubts that confusion actually exists let him try explaining the whole to a person unfamiliar with sulphuric acid nomenclature. Why not simplify matters and refer to all strengths up to fuming as per cent H_2SO_4 and from there on as equivalent per cent H_2SO_4 ? For instance take the more common grades and express them in terms of H_2SO_4 :

60 deg. B. sulphuric acid	77.67 per cent H_2SO_4
66 deg. B. sulphuric acid	93.19 per cent H_2SO_4
Oil of vitriol	93.19 per cent H_2SO_4
98 per cent sulphuric acid	98.00 per cent H_2SO_4
Monohydrate sulphuric acid	100.00 per cent H_2SO_4
20 per cent fuming sulphuric acid	104.50 per cent H_2SO_4
85.3 per cent fuming sulphuric acid	104.50 per cent H_2SO_4
104.5 per cent fuming sulphuric acid	104.50 per cent H_2SO_4
20 per cent oleum	104.50 per cent H_2SO_4
85.3 per cent oleum	104.50 per cent H_2SO_4
104.5 per cent oleum	104.50 per cent H_2SO_4

Simplicity would be gained for every one concerned by the use of one general term. Tables could be very easily revised to even percentages to avoid having common grades read in decimals. Producers marketing 60 deg. B. acid could change to 78 per cent, 66 deg. B. to 93 per cent, etc.

More confusion would be eliminated by reporting acid tonnages as tons H_2SO_4 rather than converting all to a meaningless 50 deg. B. basis.

Deper, Illinois.

THOMAS J. SULLIVAN.

Recording Pyrometry

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the September Bulletin of the American Institute of Mining & Metallurgical Engineers, there is an advanced printing of the paper entitled "Recording Pyrometry," by C. O. Fairchild and Paul D. Foote of the Bureau of Standards, wherein, on page 1646, where some details in description of our multiple recorder, the Tapalog, are given, the following statement appears:

"Consistent with the sturdy construction of other parts, the galvanometer is not made with a high resistance (only 10 to 50 ohms) and when the recorder is installed, the thermocouple circuits must be carefully made and lead resistance of definite value used."

The conclusions stated in this paragraph are drawn from the erroneous resistance values specified. With a wrong premise a wrong conclusion naturally results. Actually, the internal resistance of the Tapalog, instead of being from 10 to 50 ohms, is from 100 to 450 ohms, so that it is evident that the Tapalog is made with a high-resistance galvanometer and the thermocouple circuits do not have to be adjusted to give very definite lead resistances. Even back in 1914 and 1915, the average internal resistance of the Tapalog was running from 80 to 105 ohms, and the Tapalog neither now nor when it was first on the market has ever been equipped with low-resistance galvanometers, as indicated in the article referred to.

This statement quite unintentionally, we are assured and satisfied, greatly misrepresents one of the first high-grade pyrometer recorders developed in this country and an instrument that was called upon to do much important service in many of the arsenals and armories during the war. The authors have since made every effort to have the misstatement rectified. However, they recognize the fact that they personally are unable to set the matter right except to those who attended the recent Chicago meeting of the Mining & Metallurgical Engineers, and I would request a little of your space to correct the statement in the minds of others who have read the original paper.

WILSON-LAEULEN Co.,

By C. H. Wilson, President.

New York City.

A new mathematical journal called *Die Mathematische Zeitschrift* has been launched in Berlin. It is edited by Professor L. Lichtenstein, with a group of associates. Two volumes will appear per year.

Western Chemical and Metallurgical Field

Metallurgical Plan for Consolidated Coppermines

THE solution of a problem in metallurgical engineering is not always clear cut; certain contingencies are usually to be met in the premises and the little word "if" is often inserted. Usually, also, the present-day problems and the more complex ones require a large amount of research and comparatively large-scale operations before the metallurgist is warranted in drawing definite conclusions or in making specific recommendations. The annual report of the Consolidated Coppermines Co. for the year ended April 30, 1919, contains a metallurgical plan for the treatment of the company's ore which is submitted by Mr. Frederick Laist, who was retained by the company as a consulting metallurgist.

In the introductory paragraphs of the report, Mr. Laist states that the responsibility for the estimates of available tonnage and grade of ore reserves, together with the estimates of the mining costs, rests with the operating company, but that he assumes responsibility for all estimates of costs of ore treatment and percentage of recovery of copper as well as all recommendations relative to ore reduction plants, on the following premises, viz.:

1. That there is available for concentration a minimum of 2000 tons per day of "porphyry" ore containing not less than 1.4 per cent of copper, practically all in form of sulphide and conforming in general to the analysis given herein.

2. That there is available for concentration about 150 tons per day of "sulphide" ore containing 2.9 per cent Cu and otherwise of approximately the analysis given herein.

3. That there is available for smelting about 150 tons per day of "oxidized" ore containing 7.5 per cent copper and otherwise of approximately the analysis given herein.

It is assumed that these ores, in the quantities and of the grades named, can be delivered to the reduction works at a cost of around \$1.10 per ton for the porphyry ore, \$5 per ton for the sulphide ore and \$10 per ton for the oxidized ore for a period of not less than 10 years.

An increase in the daily production of porphyry ore to 4000 tons would make unnecessary the production of oxidized ore so far as the economy of the smelter operations is concerned.

An increase of the daily production of porphyry ore to 5000 tons would result in the production of sufficient concentrates from this source alone to maintain the smelter in economical operation.

Ten years' operations on the scale assumed herein will require 7,200,000 tons of porphyry ore, 540,000 tons of "sulphide" ore and 540,000 tons of "oxidized" ore.

On the basis thus set forth, it is recommended that a new concentrator having a capacity for 2000 tons of porphyry ore and 150 tons of "sulphide" ore be constructed. In connection with the concentrator there is to be constructed a power plant capable of generating 3000 kw., which will furnish sufficient power for water supply, operating concentrator, smelting and mining plants; and a reverberatory smelting plant capable of smelting the concentrates resulting from the above ore,

as well as about 150 tons of "oxidized" ore per day.

The concentrator is to be constructed nominally in two sections, but is to be so arranged and provided with spare grinding mills and flotation machines that a breakdown of one of these will not affect operations. Allowance is to be made for future possible extension to 5000 tons treatment per day. The crushing plant is to be built for 3000 tons per 8 hours. The power plant is to contain two 3000 kw. turbo-generator sets for 2200 volts, 60 cycle, 3 phase. Boiler capacity is to be provided for the entire 3000 kw., but about 500 kw. will probably be obtained from the waste-heat boilers in the reverberatory plant. The boilers are to be equipped with automatic stokers or possibly for pulverized coal.

The smelting plant will consist of a drying department containing four 20-ft., 7-hearth Anaconda Wedge roasting furnaces; a smelting department containing one 100-ft. x 20-ft. coal-dust fired reverberatory furnace equipped with Stirling waste-heat boilers; and a converting department containing two 12-ft. diameter Great Falls type converters and stands.

The immediate construction of a second reverberatory furnace is recommended, although it is not absolutely needed; the smelter building should at any rate be made sufficiently long to accommodate the second furnace when it is built. This will add approximately \$50,000 to the estimate and is being allowed for. The second furnace would cost about \$125,000 more and is not being allowed for.

The reverberatory plant will have a capacity of 445 tons of total solid charge per day and about 50 tons per day of molten converter slag. Of this charge 133 tons will be porphyry concentrates. Assuming that the concentrator be enlarged to 5000 tons daily capacity, 200 tons more, or a total of 333 tons, of this kind of concentrate will result. This would permit of smelting about 100 tons more of "oxidized" ore, or a total of 300 tons of cuprous material, requiring, say, 65 tons more of flux and producing 25 tons more of secondaries.

Three hundred and ninety tons per day is, therefore, the total probable future requirement of the smelter, and one additional reverberatory furnace, one more converter stand and two more drying furnaces will easily take care of this increase. This plant is laid out with this possible extension in mind.

It is estimated that there will be a saving of practically 28c. per ton of ore in favor of establishing the concentrator and smelting plant at Kimberly (instead of at Ely) and pumping the water necessary for the concentrator, in spite of the fact that the water must be pumped a total height of 967 ft. or against a total head, including friction, of 1200 ft. (600 lb. per sq.in.) and a distance of 13 miles.

This saving requires no qualification, as the cost of coal for smelting and power purposes as well as supplies would be exactly the same at Kimberly as at Ely, the same freight rate being charged to both points. This would presumably also apply to shipments of copper. Fluxes could be delivered somewhat cheaper at Kimberly than at Ely.

It is obvious, therefore, that the reduction works should be located at Kimberly, since a saving of 28c. per ton represents approximately 1.2c. per pound of copper recovered from porphyry ore, or about \$200,000 per year on a 2000-ton-per-day, or \$500,000 per year on a 5000-ton-per-day porphyry operation.

Savings to be realized by the construction of the new

plant as compared with the method of operation pursued till the end of 1918 are given herewith.

These calculations are based on the following analyses, which are taken from the metallurgical statements of the Consolidated Coppermines Co., and represent averages over considerable periods. Recovery figures and concentration ratios are based partly on the performance of the Kimberly mill, which made a recovery of about 82 per cent during the last three months of 1918, with a concentration ratio of 17 to 1 and partly on results obtained at a research laboratory:

ANALYSIS OF PORPHYRY ORE

McGill plant.	% Cu	% Ag	% Au	% Insol	% SiO ₂	% Al ₂ O ₃	% Fe	% CaO	% S
Kimberly plant...	1.455	0.046	0.013	66.1	11.9	4.4	1.1	2.8	
Average....	1.379	0.047	0.013	87.5	66.1	11.9	4.0	1.5	2.7

Assume as basis—2000 tons per day of ore averaging 1.4 per cent Cu; 85 per cent concentrator recovery; ratio of concentration 15 to 1, producing 133 tons concentrate per day.

Analysis of concentrates to be produced:

% Cu	% Ag	% Au	% Insol	% Fe	% CaO	% S
18.0	0.475	0.189	20.0	25	1.5	2.7

ANALYSIS OF SULPHIDE ORE

% Cu	% Ag	% Au	% Insol	% Fe	% S
2.9	—	—	18.0	9.6	—

Assume as basis—150 tons per day; 90 per cent concentrator recovery; ratio of concentration 4 to 1, producing 37 tons concentrates per day.

Analysis of concentrates to be produced:

% Cu	% Insol	% Fe	% S
10.5	15.0	32.0	34.0

Assume smelter recovery at 95 per cent, operating costs are estimated as follows:

Power—\$0.01 per kw.-hr.
Concentrating—\$0.85 per ton.
Drying—\$0.45 per ton.
Reverberatory smelting—\$2.35 per ton.
Converting and casting—\$10 per ton of copper.

TOTAL SMELTING EXPENSES

Crushing 275 tons ore, flux and secondaries at 15c.....	\$41.20
Drying and mixing 445 tons at \$0.45.....	200.00
Reverberatory smelting 445 tons at \$2.35.....	1,045.00
Converting 37 tons Cu at \$7.50.....	278.00
Casting and loading 27 tons at \$2.50.....	92.60

Add 10 per cent for miscellaneous.....

Cost of smelting per ton of concentrate mixture.....	5.70
Cost of smelting per lb. of copper produced.....	0.0246
Cost of concentrating per lb. of copper produced.....	0.0247

SUMMARY SAVINGS IN FAVOR OF NEW PLANT

Concentrator savings and smelting charges.....	\$1,871.00
Freight charges on concentrates.....	83.00
Smelting charges on "oxidized" ores, 150 tons at \$4.05.....	608.00
Smelting charges on "sulphide" ores, 150 tons at \$7.69.....	1,155.00
Total daily saving.....	\$3,717.00

Or on a basis of 360 days, \$1,340,000 per year.

In addition to the above there is a possibility of saving from \$400 to \$600 per day in refining and freight charges by furnace refining locally.

ESTIMATED COSTS AND EARNINGS

The total earnings of the plant outlined herewith can be approximated as follows:

Mining 2000 tons porphyry ore at \$1.10.....	\$2,200.00
Mining 150 tons oxidized ore at \$10.00.....	1,500.00
Mining 150 tons sulphide ore at \$3.00.....	750.00
Concentrating 2150 tons at \$0.85.....	1,830.00
Smelting expenses on concentrates and ore.....	1,823.00

Total daily local expenses.....	\$8,103.00
Freight to market 37 tons Cu at \$16.60.....	613.00
Refining 37 tons at \$22.00.....	815.00

Total cost of producing 37 tons Cu.....	\$9,531.00
Less credit of \$10.00 per ton for Au and Ag.....	370.00
Total net cost for 37 tons.....	\$9,161.00

or \$247.00 per ton Cu = 12.35c. per lb. Cu *
Profit in 18c. Cu = 5.65c. per lb. or per day, \$4,100.
Yearly earnings, say, \$1,500,000 less selling expenses and taxes.
* It is safe to say that under pre-war conditions, the cost per lb. of copper would have figured less than 10c.

In order to realize this estimate it will be necessary to spend some money on equipment in the mining department, which has not been allowed for in the estimate.

The plant outlined herewith is of the minimum size

to be recommended. Any smaller sized plant would necessitate less than standard sized units in the smelter and would considerably increase both concentrating and smelting costs. The plant, as proposed, will, on the other hand, make almost as good costs as a plant of twice the size.

The estimate of the plant cost given herewith does not include railway approaches to the smelter and concentrator. It does, however, include everything pertaining to the concentrator and smelter, including all office and shop buildings and equipment.

TREATMENT OF PORPHYRY ORES ALONE

In order to convey an idea of the value of the porphyry ore alone, without admixture of high-grade "oxidized" ore, the following estimate is submitted. The complete treatment of porphyry ore alone locally would scarcely be feasible on a scale of much less than 5000 tons per day. This quantity of ore would, however, yield approximately 300 tons of concentrates, which would make the total amount of material to be smelted, including fluxes and secondaries, about 425 tons per day, which would be an economical operation for one reverberatory furnace.

The cost of the operation would be about as follows:

Assume recovery in bullion of 80 per cent of 1.4 per cent Cu = 22.4 lb. per ton.

COST OF TREATMENT PORPHYRY ORE ALONE—5000 TONS PER DAY

	Per lb. Cu
Mining at \$1.10 per ton of ore.....	\$0.0491
Concentrating at \$0.85 per ton of ore.....	0.0379
Smelting at \$6 per ton of concentrates.....	0.0179
Freight at \$16.60 per ton copper.....	0.0083
Refining at \$22 per ton copper.....	0.0110
Gross cost.....	\$0.1242
Credit for gold and silver.....	0.0050
Net cost.....	\$0.1192

This cost is based on present cost of labor and supplies. Under conditions such as prevailed prior to the war a net cost of not more than 10c. per lb. and probably less could doubtless have been realized. The above estimate allows for reasonable miscellaneous expenses, but does not allow for selling expenses, war or excess profits taxes.

An operation as here outlined would produce about 40,000,000 lb. of copper per year, would yield, on an 18c. copper market, \$2,400,000 per year less selling expenses and taxes and would require an investment of about \$3,500,000 in water supply and reduction plants.

ESTIMATED COST OF REDUCTION WORKS AS OUTLINED HEREWITH

Assume daily treatment—Porphyry ore.....	2,000 tons
"Sulphide" ore.....	150 tons
"Oxidized" ore.....	150 tons
Water supply 1,000 to 1,500 gal. per min.....	\$305,740
Crushing plant.....	100,000
Concentrating plant.....	450,000
Power plants—3,000 kw.....	450,000
Drying plant.....	200,000
Reverberatory plant.....	350,000
Converting plant.....	150,000
Bins, rolling stock, shops, houses and miscellaneous.....	300,000
Engineering, drafting and contingency (say).....	\$2,105,740
Total.....	\$4,240,240
Total.....	\$2,500,000

This estimate is based on present cost of supplies and labor and is considered conservative.

The plant can be enlarged at any time, without interfering with operations, to 5000 tons of porphyry and 250 tons of oxidized ore, at an additional expense of about \$1,400,000.

The President's Industrial Conference

Second Week's Meetings See Crisis Nearly Reached on the Resolution to Take Action on the Steel Strike—Collective Bargaining Another Question Bringing Out Diverse Opinions—Compromise Is Sought

DURING the second week of its deliberations the President's Industrial Conference successfully weathered two dramatic crises which threatened its disruption, and on adjournment decided to make a further attempt to accomplish its purpose of reaching "some common ground of agreement and action with regard to the future conduct of industry." The introduction of Labor's steel strike resolution accomplished all that was expected of it in the way of warm debate and argument, and finally made necessary a decision to sidetrack it temporarily while the General Committee sought to establish a fundamental principle on which both sides could agree for the settlement of all such disputes as the steel strike. In this they were not successful, for the introduction of a resolution on the subject of collective bargaining proved as contentious as the steel strike resolution, and at the end of the week the Conference was again held together only by cool counsel, but without positive accomplishment.

CONFERENCE COMMITTED TO SERVE INTERESTS OF GENERAL PUBLIC

When the Conference convened Tuesday morning, Oct. 14, the Committee of Fifteen first recommended approval of Mr. Fish's resolution declaring that the issues to be considered were of interest primarily to the whole people of the country, and calling upon the delegates to consider themselves as representative of the entire community rather than of a specific group. This resolution was adopted with little debate and by the affirmative vote of a majority of each of the three groups. It was, however, the subject of ironical reference by Mr. Gompers, who spoke of "the momentous character, the all-pervading importance, the wonderful settlement of all troubles, involved in this radical resolution."

This matter disposed of, the Committee of Fifteen proceeded with its report involving the classification of the resolutions already offered. The Committee's report was adopted seriatim until the item of the steel strike was reached, and when the Labor Group recommended adoption there was an attempt to refer it back to the committee for further consideration. This was defeated, and there ensued debate on the question of whether the resolution was germane to the purposes of the Conference. Chairman Lane finally ruled that the question could be considered, whereupon Mr. Chadbourne of the Public Group offered a substitute resolution which provided for a committee of the Conference to consider and settle all pending

strikes and not the steel strike alone. This substitute was finally rejected by the vote of each group, and the original resolution offered by the Labor Group to settle the steel strike was taken up.

DEBATE ON THE STEEL STRIKE RESOLUTION

The committee having reported the resolution without recommendation, debate was opened by Mr. Gompers. Claiming that Labor's proposal to settle the steel strike was generous, comprehensive and yielding, Mr. Gompers reviewed the negotiations of Labor with the United States Steel Corporation, and addressed himself particularly to the attitude taken by Mr. Gary, who sat in the Public Group. Every effort consistent with the humor of the laborers had been taken by their leaders, Mr. Gompers said, to postpone a strike, and it was only after he and his associates had realized fully the situation that they withdrew their objections because a strike was inevitable. He took the position that it was better for the country that the strike should be controlled and directed by organized labor than that it should fall into the hands of radical and irresponsible leaders. These latter, he said, were on the ground, anxious and willing to take charge of the strike.

The terror of Bolshevism and the fear of the radical were held out to the Conference as the alternative to acceptance of Labor's proposal as embodied in the resolution. On this point Mr. Gompers addressed himself to the Conference as follows:

"You may win this steel strike unless you consent that it shall be adjusted after the fashion that we have so liberally proposed; but if you reject that method, and the steel strike goes on and lasts a month or two or three, and drags out, and you have won, and these men go about the country preaching the doctrine of their unbearable conditions and the tyranny which they experience and the injustices which have been meted out to them, then whatever betide, you have sown the seed and will bear the consequences. You will either come to agreement with us, or you will destroy the ability of men in our movement to stand up for the right. We will be discarded as impotent or unfaithful; and if you discard us, if you decline to enter into agreements with us, you will have somebody else to deal with and you will find them arguing and appealing to you."

Following Mr. Gompers' impassioned appeal a motion was introduced and seconded to postpone consideration of the resolution for several days in order that the Conference might study the matter more

carefully. This brought protests from the Labor Group and renewed claims of the fairness of the proposal—that two men from each group should arbitrate the strike, giving Labor only two representatives in a committee of six.

THE OBJECTIONS OF THE EMPLOYERS

Debate on this motion brought out the Employers' objections to the resolution as stated by Mr. Loree. The first objection was that the resolution was not germane to the purposes of the Conference and diverted its members therefrom. The second was "the wide field we will have to wander over if we permit ourselves to be diverted." Other objections were similar in character, one claiming that the Conference represented the executive branch of the Government and should not deal with legislative matters. In view of the fact that a Congressional committee was now investigating the strike, it would be unwise and futile for the Conference to undertake a similar investigation.

After further debate the motion to postpone further consideration of the resolution was put and declared lost, the Labor and Employers Groups voting against it.

The question then being upon the motion to adopt the resolution, the chairman proceeded to poll the groups for their vote, and it seemed as though final action was imminent. The resolution was read again, and when the vote of the Public Group was called for, Mr. Baruch asked for an adjournment for a short time for its consideration. The tension of the situation was apparent to all concerned and the gravity of any action was fully appreciated. But just as decision was about to be reached on Mr. Baruch's request for time to consider the question, a point of order was made by a member of the Labor Group that the time for adjournment was past and that the Conference was not legally in session. This point was held in order by the chairman, and he declared the Conference adjourned just as it seemed about to vote on the most contentious resolution yet brought before it. Labor undoubtedly realized that the resolution would be lost if a vote was taken at that time, and consequently saved itself for a time at least by taking refuge in adjourning under the rules.

STEEL STRIKE RESOLUTION SHELVED

When the Conference convened on the following morning, Mr. Baruch of the Public Group moved "that action on the steel strike resolution be deferred until the General Committee reports on the question of collective bargaining, and that the General Committee be directed to report on this question not later than Thursday afternoon at 2:30." This motion was carried after considerable debate, and once more action on the steel strike resolution was deferred in the hope of harmonizing the different interests and finding, if possible, common ground for a majority of the Conference. Members of the Employers Group were emphatic in their protest against forced action

in 24 hours, claiming that nobody could possibly arrive at a conclusion on so momentous a matter as collective bargaining in such a short time. Again it was urged that the settlement of the steel strike was not a proper subject for the Conference's consideration, but that the many proposals which had been offered should be taken up and discussed. The immediate production of a resolution on collective bargaining, without considering its relation to other matters, was declared inconsistent and unnatural. Nevertheless the motion to adjourn for 24 hours prevailed, and the business of the Conference suddenly was shifted from a consideration of the steel strike to the subject of collective bargaining.

STRANGE ALIGNMENT ON COLLECTIVE BARGAINING

When the Conference again convened, the General Committee offered the following resolution on the subject of collective bargaining:

"The right of wage-earners to organize in trade and labor unions, to bargain collectively, to be represented by representatives of their own choosing in negotiations and adjustments with employers in respect to wages, hours of labor and relations and conditions of employment, is recognized.

"This must not be understood as limiting the right of any wage-earner to refrain from joining any organization or to deal directly with his employer if he so chooses."

If the steel strike resolution was contentious, and if the Conference hoped to make progress by abandoning temporarily the consideration of that subject for another, it could not have selected a less fortunate proposition than collective bargaining. Nor, as the debate proceeded, could a stranger alignment of forces have been forecast than that which found Mr. Rockefeller, capitalist, and Mr. Spargo, socialist, both members of the group representing the Public, firmly advocating the claims of the Labor Group for collective bargaining. It was early apparent, however, that these two groups, representing Labor and the Public, were in harmony on the resolution, and that the Employers were in opposition. Three hours of debate ensued and the Conference again adjourned, no nearer to agreement on collective bargaining than it was on the settlement of the steel strike.

MR. ROCKEFELLER ON COLLECTIVE BARGAINING

Disclaiming any "executive position in any business corporation," Mr. Rockefeller addressed himself to the subject as "one of the representatives of the general public in this Conference." His address was replete with expressions of idealism and gave full support to the principle of representation of labor in industry, a principle which he is known to have established practically in the conduct of the Colorado Fuel & Iron Co. Parts of his address follow:

"We have been called together to consider the industrial problem. Only as each of us discharges his duties as a member of this Conference in the same high spirit of patriotism, of unselfish allegiance to

right and justice, of devotion to the principles of democracy and brotherhood with which we have approached the problems of the war, can we hope for success in the industrial problem, which is no less vital to the life of the nation.

"The world position which our country holds today is due to the wide vision of the statesman who founded these United States and to the daring and indomitable persistence of the great industrial leaders, together with the myriads of men who with faith in their leadership have co-operated to rear the marvelous industrial structure of which our country today is so justly proud.

"This result has been produced by the co-operation of the four factors in industry, labor, capital, management and the public, the last represented by the consumer and by organized government. No one of these groups can alone claim credit for what has been accomplished. Just what is the relative importance of the contribution made to the success of industry by these several factors and what their relative rewards should be are debatable questions. But however views may differ on these questions, it is clear that the common interest cannot be advanced by the effort of any one party to dominate the other, to arbitrarily dictate the terms on which alone it will co-operate, to threaten to withdraw if any attempt is made to thwart the enforcement of its will. Such a position is as un-American as it is intolerable.

"There are those who believe that legislation is the cure-all for every social, economic, political and industrial ill. Much can be done by legislation to prevent injustice and encourage right tendencies, but legislation will never solve the industrial problem. Its solution can be brought about only by the introduction of a new spirit into the relationship between the parties to industry—a spirit of justice and brotherhood.

PERSONAL RELATIONSHIP IS NEEDED

"The personal relationship which existed in bygone days is essential to the development of this new spirit. It must be re-established; if not in its original form, at least as nearly so as possible. In the early days of the development of industry, the employer and capital investor were frequently one. Daily contact was had between him and his employees, who were his friends and neighbors. Any questions which arose on either side were taken up at once and readily adjusted. A feeling of genuine friendliness, mutual confidence and stimulating interest in the common enterprise was the result.

"How different is the situation today. Because of the proportions which modern industry has attained, employers and employees are too often strangers to each other. Personal contact, so vital to the success of any enterprise, is practically unknown, and naturally, misunderstanding, suspicion, distrust and too often hatred have developed, bringing in their train all the industrial ills which have become far too common. Where men are strangers and have no points of con-

tact, this is the usual outcome. On the other hand, where men meet frequently about a table, rub elbows, exchange views and discuss matters of common interest, almost invariably it happens that the vast majority of their differences quickly disappear and friendly relations are established. Much of the strife and bitterness in industrial relations results from lack of ability or willingness on the part of both labor and capital to view their common problems each from the other's point of view.

"While obviously under present conditions those who invest their capital in an industry, often numbered by the thousand, cannot have personal acquaintance with the thousands and tens of thousands of those who invest their labor, contact between these two parties in interest can and must be established, if not directly, then through their respective representatives. The resumption of such personal relations through frequent conference and current meetings, held for the consideration of matters of common interest such as terms of employment, and working and living conditions, is essential in order to restore a spirit of mutual confidence, good will and co-operation. Personal relations can be revived under modern conditions only through the adequate representation of the employees. Representation is a principle which is fundamentally just and vital to the successful conduct of industry. This is the principle upon which the democratic government of our country is founded. Surely it is not consistent for us as Americans to demand democracy in government and practice autocracy in industry.

"What can this Conference do to further the establishment of democracy in industry and lay a sure and solid foundation for the permanent development of co-operation, good will and industrial well being? To undertake to agree on the details of plans and methods is apt to lead to endless controversy without constructive result. Can we not, however, unite in the adoption of the principle of representation, and the agreement to make every effort to secure the indorsement and acceptance of this principle by all chambers of commerce, industrial and commercial bodies and all organizations of labor? Such action I feel confident would be overwhelmingly backed by public opinion and cordially approved by the Federal Government. The assurance thus given of a closer relationship between the parties to industry would further justice, promote good will and help to bridge the gulf between capital and labor."

THE CASE FOR LABOR

Mr. Morrison, secretary of the American Federation of Labor and a member of the Labor Group, acted as spokesman for Labor in debating the resolution. He addressed himself first to a proposal of the Employers Group on the open shop, that "no employer should be required to deal with men or groups of men who are not his employees or chosen by and from or among them." This, of course, was the es-

sence of the Employers' anticipated opposition to the resolution on collective bargaining, and Mr. Morrison attacked it as a principle that "violates established and prevailing custom in industry in the civilized world, nullifying the good faith of all the other principles advanced in its program by the Capital Group." He then cited the custom of collective bargaining in the United States among the 113 international trade unions composing the American Federation of Labor; recalled the declaration of the War Labor Board and the Director General of Railroads on the subject; cited the recognition of the principle of collective bargaining in Canada, Great Britain, Sweden, Norway, Australia and Germany.

"Open shop" is a deliberate negation of the unavoidable necessity for the organization of labor. When wage-workers are not united, employers play one worker against another in competition. They quote a tenth man, unemployed, as a menace to nine men in their employment. They take advantage of dull seasons, when unemployment is at its worst, to establish permanently wages and conditions to which the most needy workers must then give their consent. The more liberal employers themselves are finally obliged by low-wage-paying competitors to reduce wages in order to meet the price of products in the market reached through the cheapest labor costs.

"That inevitable tendency in finance by which the worse currency drives out the better—Gresham's law—is equally true in its application to labor. The employers of sweatshop labor, prison labor, child labor, non-union, woman's labor and cheap foreign labor, in various industries have repeatedly captured markets from employers conscientiously endeavoring to uphold recognized American standards. The sole effective antidote to this social disease has been the trade union."

JOHN SPARGO'S VIEWS

Mr. John Spargo, speaking as a "convinced socialist, believing that this industrial and social order must give place to another," followed Mr. Morrison, but would have preferred to follow Mr. Rockefeller directly because in so doing he might help to symbolize what he believed to be the governing purpose of the Public Group. Like many of the other speakers in the Conference, he referred to the solidarity and unity of purpose displayed by America in the war, and the necessity for similar action in the face of industrial peril. "That spirit," he said, "has not only guided my own part, small as it is, in this group, but it is the spirit in which this group has come together; and there is nothing unusual in the fact that Mr. Rockefeller, at one end, if you will, of our social scale, and I, at the other end, unite in a common policy here and now." Pleading for union of the different elements of the Conference, Mr. Spargo said that class consciousness should not be exhibited by the groups on his right and left. "What we need is an intense sense that America cannot afford to be

divided in herself if she is to prevail in the great onward march of the nations."

Addressing himself to the Employers, he said: "I ask you to consider for a moment where you place yourselves when you say that you will not permit your men to be represented by representatives of their own choosing, because, forsooth, those representatives may not be chosen from your plants. Are you going to say that you, with your vast resources, you who can command the brain and the service of the ablest counsellors in the land, in addition to starting with the advantage of great education, are you going to say, 'We must hire as our representatives the best brains that we can hire, but when we deal with these poor helpless men who come and are bewildered in the strange and complex life so unfamiliar to them, we insist that we will put our high-priced attorney on one side of the table and the poor foreign workman with his little command of English on the other.'"

Mr. Feiss of the Public Group supported the resolution and stated that he "would have gone still further and urged every employer to assist in organizing his men so that they might have a coherent and collective voice in the determination of conditions of employment in which they must always be interested."

Mr. Endicott, of the Public Group, speaking as "one of the largest employers of labor in this country and the very largest employer of labor in my line that there is in the world," supported the resolution for collective bargaining. It developed that he had been responsible for the addendum to the resolution which provides that the wage-earner might refrain from joining any organization of employees and might deal directly with his employer if he so chose.

THE ATTITUDE OF THE EMPLOYERS

All of the preceding debate had ensued without a statement on the part of the Employers, who, incidentally, had not supported the resolution in the Committee of Fifteen. Speaking for that group, Mr. Fish said that one reason for opposing the resolution was its indefiniteness. He contended that any resolution emanating from the Conference and going to the country as its expression should, if possible, be beyond misunderstanding. He felt, furthermore, that the matter of collective bargaining was inextricably bound up with other matters which had not even been considered by the Conference and which, when considered, might be found to affect the attitude toward this question. The proposition of the "open shop," for example, he felt to be so intimately interwoven with collective bargaining that it would be unwise to consider the one without the other. He defined the open shop as one "in which membership or non-membership in any association is of no more consequence in determining whether or not a man shall be hired or discharged than his membership in a secret fraternity or his membership in a church or his race or creed." The proposition of the open shop he believed

to be attacked by the resolution on collective bargaining because it recognized the principle of allowing non-employees or outsiders to represent the workers in a plant. He said that the employers were not opposed to collective bargaining as a principle, but they were opposed to the idea that the employer should be required to deal with a labor union as a representative of his men. "Practically what that (the resolution) means is that the men to be selected by the employees, outside their number, are to be labor union men. That is the practical thing that confronts us, and any pronouncement on the part of this Conference that such is forced on the employers of this country seems to us improper, unwise and likely to have the most serious consequences to our industries." Mr. Fish acknowledged the "right" of employees to organize in trade and labor unions, but he denied that it was a "right" to be represented by representatives of their own choosing, when such representatives probably would have no knowledge of local conditions and who could not bring into the negotiations the single-minded devotion to the cause of the men they were representing.

Mr. Fish then moved to refer the resolution back to the Committee of Fifteen for further consideration. The motion was seconded, but the debate continued. Labor delegates expressed the opinion that it would be useless to refer the resolution back to the committee, because Labor had gone as far as it would in making concessions in the verbiage of the statement. They contended that the open or closed shop had nothing to do with the matter, and should not be injected into the debate.

THE ROLE OF MANAGEMENT

By far the best presentation of the case against the wording of the resolution was made by Mr. Homer L. Ferguson, president of the Chamber of Commerce of the United States and manager for the Newport News Shipbuilding Co., who is a member of the Employers Group. Mr. Ferguson spoke from the viewpoint of management, "the despised class that stands between the wage-earner and the owner." He maintained that in the settlement of any controversy between employers and employees, the terms must be such as would enable a self-respecting man to act as manager. "In handling the problem of the individual man in the individual plant, the conditions of the plant must be considered, the conditions locally surrounding the employment must be considered.

"The right to be a representative of a man in any controversy carries with it the obligation that the representation of that man shall be a primary consideration; that it shall be the first thought of the man who does the representing; that ulterior motives shall not be present. My right to employ a lawyer is an inherent right. I also have the right to demand that that lawyer shall be single in my employment. We do not ask as managers in isolated plants to have men meet with our representatives. We do not employ

lawyers to meet them. As a matter of fact, business men do not employ lawyers to meet each other. When a lawyer is usually brought into any business deal that I am familiar with, an attitude of suspicion is at once created, and of antagonism.

"Now, if we are to deal with this in a spirit of friendliness, let me picture to you the position of a manager in dealing with those representatives of the men. A man comes to town from nowhere in particular, inaugurates meetings, secret for the most part; sticks out signs, starts an agitation, agitates political economy that is strange to most of the books and strange to most of the gentlemen here, except those who have heard it; organizes up the shops, presents demands which frequently illustrate in themselves that he does not know what he is talking about; claims to represent the men; the men walk out or threaten to walk out. Then we managers are told, 'You must meet that man, you must deal with him; you must meet him because we, the men, choose him to meet with you.' He is the choice of the men, yes, but the choice was made before they chose him. A representative of a great federation, representative of that federation before he represented the men; representative of it during his representation; a representative of that federation after he had left town and left behind him men who feel that much of the trouble he created could have been avoided.

"The principle [involved here] is that a man shall not be compelled to join the unions. The addendum put on this resolution is that a man shall not be compelled. It does mean it to the gentlemen that put it on, but I want to state, gentlemen, that that is an agreement that the gentlemen here cannot settle. Why? When you meet with the men, you do what? You do what has caused more strikes than any other cause, you recognize the union; you recognize the union representative, not just the local union, but the American Federation of Labor. All right. In recognizing that what do you do? You serve notice on the men throughout the plant, who may or may not belong, that the union has been recognized, and you tell them as plainly as words can that if they desire representation they should get in the union, and you tell them to, and the men tell them that they should get in and do their share.

"I have no objection to employing union men, and I hope that our concern has not discriminated against them for years; but I say that to establish a condition, whether it is established in England, in Sweden or any other place, whereby a man may not work freely without coercion, without being interfered with, is to establish an un-American condition, and is to set up a power that, in course of time, will involve us in the troubles of old countries, and by that power even we may lose our representative form of government.

"We cannot shift the seat of government from the other end of the avenue [Congress] to this hall. Great authority such as these gentlemen [Labor] ask, if conferred on them, would mean the creation of a

power in this country which, the greater it became, the more antagonism it would encounter. Mere size in this country is a tremendous thing; is a matter of tremendous moment to people.

"I am not speaking in opposition to unionism, but I am saying this, that this great country was built on the basis of equilibrium established through opposing forces, and it would be a bad thing for all of us to believe in one way only of curing our ills, either industrial, political or domestic. Power without responsibility, and an adequate responsibility in keeping with that power, is a thing that cannot be, in a free country.

"I made this remark this morning to one of the gentlemen from the other group, and he said: 'It sounds like you were speaking of the steel trust.' I say that I am speaking of any power, whether the power of capital or the power of labor, that is created in this country, and that is not clearly defined as to its responsibility—the creation of a great super-government, as it were, with greater power to settle the destinies of men than our chosen representatives.

"As an employer I do not want willingly to be put in a position of saying to a man, 'You cannot get your just deserts unless you join [the union]. You must join this or be forced out of the shop. Affairs will be so disagreeable for you that you either join this organization or get out.' And yet I have the hope that in the treatment of the men in the shop we hard-hearted managers, who have grown up with, belong to and associate with the men every day know how to treat men. We have learned that the higher we get it is 'come' instead of 'go'; and some of us have found out that great responsibility does not mean great power. He serves best who feels that he is the servant of all the men in a plant. Dictatorial orders do not exist in the settlement of wages. Men do not sit around tables and settle them at all. There are conditions which I cannot control, and which no man can control. But, in speaking the language of democracy, let us be careful that we do not indulge in practices of autocracy and create in this great country power with authority almost supreme, but without corresponding responsibility."

At the close of the debate near the hour for adjournment, Labor moved to remain in session until the matter was disposed of, but this was voted down and the Conference adjourned until the following morning.

MOTION TO RECOMMIT WITHDRAWN

When the Conference again convened Mr. Fish withdrew his motion to recommit the resolution on collective bargaining to the Committee of Fifteen. Further debate then ensued on the motion to adopt the resolution. Mr. Wheeler of the Employers Group then introduced a substitute motion which embodied the ideas of the Employers in an effort to reach a compromise. The bone of contention, as before, was the clause "to be represented by representa-

tives of their own choosing." Gradually the impression grew that too much haste had been urged in reporting the original resolution on collective bargaining as well as in drafting the substitute on the part of the Employers. It was apparent from the debate that no new arguments were being brought out and that another deadlock was on as strong as the one which practically brought about the temporary abandonment of the steel strike resolution. Suggestion that Labor had drawn the resolution on collective bargaining brought out the fact that the first clause was drafted by Mr. Russell and the second by Mr. Endicott, both of the Public Group. The Employers expressed abiding faith in the country and the Government, and declined to be scared into action by radicals. The issue still remained as to whether employers should be required to accept union leaders as representatives when troubles occurred in open shops; as to whether agents of the unions would be in fact single-minded representatives of the workers. Much oratory shed no new light on the subject.

Messrs. Loree, O'Leary, Compers, Spargo and others spoke at great length, and after six hours of debate the hour of afternoon adjournment arrived with no settlement in sight. Again Mr. Chadbourne, chairman of the Committee of Fifteen and a member of the Public Group, sought to save the Conference from disruption through disagreement, and offered a resolution to adjourn, coupled with the motion to recommit both the original and substitute resolutions on collective bargaining to the Committee of Fifteen to see whether the differences might not be harmonized if more time were taken for calmer consideration. His resolution also called for adjournment over Saturday and Sunday until Monday morning, Oct. 20, at 9:30. Mr. Chadbourne thought that the debate had brought out new matter on both sides and that this should be considered before taking final action. There was considerable opposition to this suggestion of Mr. Chadbourne but it finally carried and the Conference adjourned. Thus ended the second week of the meeting, with two vital Labor resolutions still unsettled and in the balance.

Undoubtedly both the steel strike resolution and that relating to collective bargaining would have been voted down if a vote had been reached as Labor desired. The Public Group, acting as a mediator, may be said to have saved both from defeat.

The Committee of Fifteen met on Saturday to reconsider both resolutions on collective bargaining, and it is reported that all are agreed that the subject was brought before the Conference prematurely. Hope is held out for compromise on which all can agree, because there are but slight differences in wording to be reconciled, although those differences carry vital consequences. If the choice of representatives of the workers could be accomplished "free and undisturbed," it is believed that the Employers can find their way clear to agree to the resolution. The third week of the Conference will tell.

Chicago Meeting of the American Electrochemical Society

Annual Fall Meeting Marked by Large Attendance and Presentation of Important Papers That Aroused Much Discussion—Symposium on Catalysis—Session on Plating and Organic Electrochemistry

THE 36th general meeting of the American Electrochemical Society was held in Chicago, Sept. 23 to 26 inclusive in conjunction partly with the meeting of the American Institute of Mining & Metallurgical Engineers and the Fifth Annual Exposition of Chemical Industries. The first day's program was abandoned on account of the steel strike, and the members reluctantly gave up the proposed trip to the Indiana Steel Co. at Gary. A joint session on the metallurgy of iron and steel was nevertheless held with the A. I. M. E., which will be reported in the proceedings of that body.

The first business before the society on the second day was the consideration of the report of the committee on the algebraic signs of potentials. This committee has been deliberating for some time and has been unable to make a previous report. Even at this time they were unable to agree, and a report was made to which four subscribed and one dissented.

ALGEBRAIC SIGNS OF POTENTIALS

The report of the committee, approved by Messrs. CARL HERING, M. DEK. THOMPSON, F. C. FRARY and W. D. BANCROFT, and dissented from by O. P. WATTS, is as follows:

"The committee recommends that the signs given to the potentials of electrodes be those which represent their electric charges with reference to the solutions. An element like zinc, which becomes negatively charged with respect to the solution, is therefore given a negative sign, and the sign of the calomel electrode then is plus. In charging and discharging a storage battery the current is reversed, but the polarity remains the same. This recommendation is in agreement with the more generally adopted international practice. The assumed absolute zero of potential or zero of reference should accompany the data."

The following appendix to the committee's report was presented by Dr. CARL HERING, chairman:

"In general a plus sign implies the adjective 'more' or 'higher' and a negative sign 'less' or 'lower.' Hence in the present case a plus sign implies a relatively greater activity and a negative sign a relatively less activity. One of the objections which has been made to giving metals like zinc the negative sign, is that these metals are in general the ones which are the more active from the chemical standpoint, and their chemical potential or activity would therefore naturally be given the plus sign. There is therefore an apparent disagreement between the chemical activity and the electrical activity, when as a matter of fact chemical and electrical activities in general go together.

"It is now known, however, that it is the negative electrons which are the active ones and that therefore the flow of an electric current is in fact in the opposite direction to what has long been and is still being conventionally assumed. A greater charge of negative electrons therefore represents a greater electrical activity. Hence by giving the negative sign of potential to metals like zinc which are in general the more active

from a chemical standpoint, it brings the chemical activity and the electrical activity into agreement with each other.

"Another source of confusion is that the direction of flow of the current in the external circuit when referred to the poles or terminals is necessarily the opposite to that in the interior of the cell, dynamo or other source. That is, if it is assumed conventionally to flow from the positive to the negative pole in the external circuit, it necessarily flows from the negative to the positive pole in the interior of the cell. Hence in connection with the signs of the potentials of electrodes it makes a difference whether one is referring to the external or to the internal part of an electric circuit. Referred to the external circuit, the chemically more active metals like zinc are generally negative, and are the ones to be connected to the negative pole of a voltmeter."

Study of the Alloy Manganin

MESSRS. M. A. HUNTER and J. W. BACON presented a paper on manganin, giving the results of an investigation into the resistivity and the temperature coefficient of resistivity of this alloy of copper, manganese, nickel and iron. The authors reach the following conclusions:

1. The percentage of manganese between the limits used affects the resistivity of the wire, but has no effect on the temperature coefficient of resistance.
2. The presence of iron affects the temperature coefficient to a considerable degree. Those wires in which the iron content was low did not show the temperature coefficient reversal which is characteristic of a manganin wire. The results show that the presence of iron up to 1 per cent improves the temperature coefficient of the resulting alloy.
3. We have confirmed the observation that during the annealing of the wire scrupulous care must be observed to avoid its oxidation.
4. We have further confirmed the observation that in order to stabilize the wire it is sufficient to anneal it at 150 deg. C. in an oil bath for a period of 5 hours.

Depreciation of Dry Cells

In a paper by Mr. A. J. HELFRECHT the author endeavored to show how closely the method of judging cell deterioration, called "flash test," approached actual measurements of capacity through discharging the cells. Comparative curves for the different sizes of cells tested are given in the paper. From the data gained by this investigation the accompanying table has been compiled indicating reasonable depreciation of the four important sizes of small cells.

Inches	Size of Cells		Per Cent Depreciation per Month		
	Centimeters		First Two Months	Last Ten Months	
2 1/4 x 1 1/2	5 7/8 x 3 2		0.0	2.1	
1 1/2 x 1 1/4	4 6/8 x 2 2		0.25	4.0	
1 1/4 x 1 1/4	4 8/8 x 1 6		2.0	5.5	
1 1/8 x 3/4	4 x 1.4		2.0	5.5	

The Activation of Carbon

This paper, by Dr. N. K. CHANEY of the Research and Development Laboratory of the National Carbon Co., was one of the most important offered at the meet-

ing. It embodies a careful study of the properties of carbon which were utilized during the war for defense against toxic gases. "Activated carbon" is a new article of commerce brought into existence by the war. The investigation of the adsorptive properties of carbon resulted in the development of a general theory dependent on two experimentally established postulates:

(1) That elementary carbon (other than diamond and graphite) exists in two modifications, "active" and "inactive," or *alpha* and *beta*.

(2) That all "primary" amorphous carbon consists essentially of a stabilized complex of hydrocarbons, adsorbed on a base of "active" or *alpha* carbon.

The active modification of carbon is characterized by a high specific adsorptive capacity for gases, etc. The inactive modification of carbon exhibits no special adsorptive capacity whatever.

In addition to this distinction in specific adsorbing power, active and inactive carbon differ in two other important particulars, *i. e.*:

(1) Temperature of formation.

(2) Chemical activity, or susceptibility to oxidation.

The active modification is formed whenever carbon is deposited at relatively low temperatures by chemical or thermal decomposition of carbon-bearing materials; in general below 500 to 600 deg. C.

The inactive modification results from similar decomposition at higher temperatures, in general above 600 to 700 deg. C.

The active form is rapidly attacked by oxidizing agents. Dr. Hulett has shown that slow oxidation occurs at room temperatures. The inactive form is relatively stable toward oxidizing agents, resembling graphite in this particular.

It is possible for the first time to prepare intelligently such active carbon on a large scale from whatever sources of carbon-bearing material may be cheapest, or most desirable for the particular purpose in view.

To sum up, active carbon is essentially a special form of pure amorphous carbon, deposited at low temperatures and free (1) from adsorbed stabilized hydrocarbons which are normally associated with it and which lessen its power of combining with other substances; (2) from inactive carbon formed by gas treating, *i. e.*, by the decomposition of hydrocarbons upon its surface at high temperatures.

Penetration of Iron by Hydrogen

This paper, by T. S. FULLER of the Research Laboratory of the General Electric Co., discussed experiments showing the effect of various conditions on the penetration of iron by nascent hydrogen at temperatures from 20 to 100 deg. C. Following is an abstract:

It is well known that iron at room temperatures is impermeable to gaseous or molecular hydrogen, but that at higher temperatures it becomes more or less permeable. It is not so well known, perhaps, that iron at room temperature is permeable to nascent or atomic hydrogen.

This paper describes experiments which were performed during an investigation of the penetration of iron by atomic hydrogen at temperatures between 20 deg. and 100 deg. C.

The apparatus used consisted of a $\frac{1}{8}$ -in. seamless iron tube, plugged at the bottom, and sealed at the top to a glass U tube, having one arm closed and calibrated and the other open. The whole apparatus was completely filled with mercury and when in operation hydro-

gen penetrated the iron tube, and quickly rose and displaced the mercury in the closed and calibrated arm of the U. A large number of these units were used.

It was found that hydrogen penetrates iron under a great variety of conditions, all of which influence the rate.

(1) The velocity of penetration is greater for a unit immersed, without electrical connections, in 1 per cent sulphuric acid than for units electrolyzed as cathode in a like solution, with such current densities as were tried.

(2) The rate for electrolyzed units is influenced by the current—the higher the current, the higher the rate, but the relation is not a straight line function.

(3) The penetration velocity increases with each successive electrolysis, provided rest periods do not intervene, or with acid "pickling."

(4) The effect of rest or moderate heating upon units which have been electrolyzed or pickled is to restore the original resistance of the iron to the passage of hydrogen.

(5) Temperature has a marked effect, the rate of penetration increasing with the temperature. The rate of 90 deg. C. for an iron unit made cathode in 1 per cent sulphuric acid with a current = 0.2 amp. is 14 times its rate under similar conditions at 20 deg. C.

(6) The velocities of penetration for units electrolyzed in 1 per cent solutions of potassium sulphate and sodium hydroxide, and in tap water are about equal and are $\frac{1}{2}$ to $\frac{1}{5}$ the velocity of units electrolyzed in 1 per cent sulphuric acid.

(7) Hydrogen produced by the reaction between tap water at temperatures from 50 to 100 deg. C. and iron, or between steam and iron, penetrates the metal at a rate depending directly upon the temperature.

(8) The velocity of penetration for 3 per cent nickel steel is the same as that for iron.

(9) Hydrogen does not penetrate copper at a temperature of 20 deg. C.

(10) The rate for tinned iron is greater than for iron, and for galvanized, sherardized and coppered iron is less.

(11) No evidence of sulphates could be found inside a unit which had been pickled in sulphuric acid and in which 2.4 cc. of hydrogen had collected.

(12) No hydrogen penetrated a unit immersed in a solution of 1 per cent sulphuric acid plus 1 per cent potassium dichromate in 96 hours.

(13) The gas which was collected in one of the units was analyzed and found to contain 95 per cent hydrogen and 5 per cent of an uncombustible gas, possibly nitrogen.

I wish to offer the following explanation of the manner in which hydrogen is forced through iron tubes having walls $\frac{1}{8}$ in. in thickness: Atomic hydrogen which has been liberated by the current, in the case of units which were electrolyzed, or by the reaction between metal and solution, in the case of units which were not electrolyzed, penetrates the surface of the iron where gaseous or molecular hydrogen is later formed. Iron at room temperatures is impermeable to the latter. The atomic hydrogen continues to penetrate the surface of the metal rapidly and to form molecular hydrogen. The latter can escape only very slowly and as a pressure, sufficient to force the gas through the metal, is built up. It is a pressure built up in this way which also results in the well-known phenomenon of the cracking of hardened steel when "pickled" in acid.

Effect of Amalgamation on Single Potential of Aluminum and Its Alloys With Cu, Zn and Ni

In two papers on this general subject Messrs. LOUIS KAHLBERG and J. A. MONTGOMERY, University of Wisconsin, showed that by measuring the single potential of aluminum in a $\frac{1}{2}$ molar solution of aluminum chloride at room temperature, by means of the calomel electrode, much higher values were obtained with amalgamated than with unamalgamated aluminum, due to the removal of the coat of resistant oxide by the mercury. They showed also that the measurements were actually the single potentials of the aluminum and not those of an aluminum amalgam.

The highest value obtained was a 5-second reading of 1.089 volts, compared with Neumann's value of 1.01. A series of "instantaneous" readings gave approximately the same value. The most interesting results of all were the potentials of amalgamated and unamalgamated aluminum in a $\frac{1}{2}$ molar solution of sodium hydroxide. A potential of 1.17 volts was obtained for both amalgamated and unamalgamated aluminum.

After the authors had found such a great change in the single potential of aluminum in a $\frac{1}{2}$ molar aluminum chloride solution as a result of amalgamation, they decided to see to what extent amalgamation would change the potentials of the alloys of aluminum in the same electrolyte.

Just as aluminum, when amalgamated, gives a much higher potential than when it is unamalgamated, so the alloys of Al-Cu containing less than 50 per cent of copper have their potential greatly increased by amalgamation. The greater the per cent of aluminum, above 50 per cent of aluminum, the higher the resulting potential of the alloy.

With regard to Al-Ni it is evident that by amalgamation the initial potentials of alloys which contain less than 35 per cent Ni are much higher than the potentials of unamalgamated specimens. In the case of both Al-Cu and Al-Ni there is a break in the curve of the readings on amalgamated specimens, occurring at about the eutectic for each series. From the data on Al-Zn alloys it was concluded that they do not form definite compounds, but a series of solid solutions. The eutectic located by freezing and melting-point data has not effect on the potential curve.

Electric Furnaces and Electric Heat

In a joint session with the A. I. M. E., Mr. F. A. J. FITZGERALD presented two papers, one on a new radiant resistor furnace and the other on an electric furnace for experimental work. The radiant resistor furnace for the distillation of low-grade or scrap zinc was built and operated at the FitzGerald Laboratories and produced several tons of refined zinc. The best results were obtained with a current of approximately 845 amp. at 65 volts or 55 kw. With this power the output was about 50 kg. refined zinc per hr. The complete paper will be published in a later issue. The other paper gave details of design of a furnace that had been found useful in experimental work on account of being cheap and easy to build.

The use of electric heat in the typewriter industry was discussed in a paper by A. M. CLARK, describing an electrically heated oven for baking japan on parts of typewriters. Compared with gas- or oil-heated ovens, the electric oven showed economy and better results.

Symposium on Catalysis

Friday morning and a part of Friday afternoon were devoted to a highly interesting discussion on catalysis, in which about twenty members of the society participated. The subject was introduced by Professor HUGH S. TAYLOR of Princeton University, who referred to the catalyzer as the "chemical parson," with this distinction, that in the case of chemical processes there may be more than two contracting parties. Prof. Taylor then cited a number of well known catalytic reactions, such as the oxidation of SO_2 in the presence of platinum (contact process); the oxidation of ammonia (Ostwald process); and the hydrogenation of fats in the presence of nickel.

SOME PROBLEMS IN CONTACT CATALYSIS

Professor WILDER D. BANCROFT of Cornell then presented a paper on "Some Problems in Contact Catalysis," which follows:

There seems to be no doubt that nickel splits ethyl alcohol into acetaldehyde and hydrogen because of the selective adsorption of hydrogen by nickel. The splitting of ethyl alcohol into ethylene and water by alumina is evidently due to the selective adsorption of water by alumina. In line with this is the fact that presence of water decreases the yield of ethylene in the case of alumina and that presence of hydrogen decreases the yield of acetaldehyde in the case of nickel. These results are entirely satisfactory qualitatively, but they are not so good quantitatively. In the making of ethylene from alcohol for war purposes, it was found desirable to mix a lot of steam with the alcohol. One effect was a better heat control and the reaction was run at a higher temperature than would have been possible without the steam; but it is a little difficult to see how selective adsorption of water can play an important part in the presence of a considerable amount of water vapor. While the general theory is sound, there are details here which call for further study.

A catalytic agent ceases to function if it agglomerates so that its adsorbing power becomes negligible or if it adsorbs something which is not readily removed and which therefore cuts down the adsorption of the reacting substances. We know that if the reaction products are not removed rapidly from the catalytic agent, the reaction will slow down.

My attention has been drawn recently to several cases in which a reaction comes apparently to a standstill although no equilibrium has been reached. The experimental data are not as satisfactory as I should like; but I think that the results should be put on record for what they are worth. Phosgene reacts with water to give carbonic dioxide and hydrochloric acid,

So far as we know, this reaction is not reversible, and it actually runs to an end in presence of an excess

of water. In presence of concentrated hydrochloric acid the rate of hydrolysis is practically negligible. The only way that I can see to account for this is by assuming that water and phosgene do not react by themselves and that the reaction takes place solely in contact with the walls of the containing vessel. When these are coated with a film of hydrochloric acid of sufficient concentration, no phosgene is adsorbed to speak of and no reaction takes place. The hydrolysis should be studied with different concentrations of acid and with a varying ratio of wall surface to mass of solution.

Trichloromethylechlorformate, $\text{ClCO}_2\text{CCl}_3$, or superpalite, as it has been called, decomposes to carbon tetrachloride and carbon dioxide in presence of alumina,

and to phosgene in presence of ferric oxide,

The reverse reaction has never been made to take place to any measurable extent. Some superpalite and ferric oxide were placed in a glass tube connected with a closed manometer. There was rapid decomposition at first, as shown by the increase in pressure; but, before long, the reaction came apparently to an end. On raising the temperature, the reaction went a little farther and did not reverse when the temperature was brought back to its original value. This experiment was not checked sufficiently to make me willing to guarantee the results; but it looks as though the ferric oxide was poisoned and that when the temperature changed, more superpalite came in contact with the catalytic agent and was decomposed. If this is the true explanation, it suggests one interesting line of experimentation. When ethyl butyrate is treated with a small amount of enzyme, the decomposition only proceeds a little way. It seems probable that with an oscillating temperature it might be possible to carry the reaction much farther with the same amount of enzyme.

If we were to put calcium carbonate in dilute sulphuric acid and if the resulting calcium sulphate were to form a coherent film over the surface of the calcium carbonate, the reaction would come to an end as soon as the surface of the calcium carbonate was coated over completely. The apparent equilibrium would be more or less independent of the concentration of the acid. For a given size of calcium carbonate particles apparent equilibrium would be reached when a definite amount of calcium sulphate had been reached. This is self-evident in a case of this sort; but the matter is not always quite so obvious. A certain war gas, which we will call *A*, gives a solid hydrolysis product. The same amounts of *A* were treated with 250 cc. of water and with 1000 cc. of water. When apparent equilibrium was reached, the acid was four times as concentrated in the first case as in the second. Experiments were then made with dilute hydrochloric acid solutions instead of with water, and it was found that the presence of hydrochloric acid in moderate amounts had practically no effect on the

amount of hydrolysis. The hydrolysis took place in every case until the ratio of hydrolysis product to undecomposed substance was a constant. Of course it should have been shown that this ratio varied with varying crystal size; but there were a good many loose ends after the war and this was one.

Some recent experiments by Lind¹ can be looked upon as a displacement of equilibrium by a catalytic agent if one so wishes. Radium emanation decomposes liquid water into hydrogen and oxygen; but causes hydrogen and oxygen to combine. If the emanation is placed in the liquid phase, hydrogen and oxygen will be formed and will escape into the vapor phase. If the emanation is moved up into the vapor phase, the reverse reaction will take place.

DISCUSSION

Dr. COLIN G. FINK in discussion took exception to Bancroft's definition of a catalytic "poison." Fink divided poisons into two distinct classes: First, those that affect the catalyzer, and second, those that affect one or more of the reacting components or the product of the reaction. It is also conceivable in reactions that pass through one or more intermediate stages that one or the other intermediate product is affected by the poison, whereas the original components are immune. Mr. M. L. WEISS referred to his study of the reaction

and mentioned that the catalyzer he used seemed to have no affinity for either of the components of the reaction.²

Dr. TAYLOR, in reply, pointed out that unless very careful experiments were made, it was often difficult to remove the adsorbed material from the catalyzer and cited the case of finely divided iron retaining moisture at temperatures as high as 500 deg. C. Mr. W. R. MORR of Cleveland referred to his photochemical investigations and emphasized the point that the merest trace of iron catalyst was sufficient to bring the reactions into play. Mr. V. R. KOKATNUR of Niagara Falls suggested that the difference in behavior of the catalyst Al_2O_3 as compared with that of the catalyst Fe_2O_3 in the decomposition of superpalite as mentioned by Bancroft might be attributed to the greater tendency of iron to form carbonyl.

FURTHER PROBLEMS IN CONTACT CATALYSIS

A paper on "Further Problems in Contact Catalysis" was next presented by Dr. H. S. TAYLOR. He emphasized that the first striking feature common to most of the contact agents successfully employed in catalytic reactions was the porous or finely divided state of the material. For example, the light, porous hydrated oxide of iron used in the fractional oxidation of hydrogen sulphide to sulphur in the purification of illuminating gas. Catalysts of this porous type usually adsorb greater or lesser quantities of gases. But Patrick's silica gel adsorbs and yet does not act as

¹ *Trans., Am. Electrochem. Soc.* (1918), Vol. 34, p. 211.

² The identity of the catalyzer was not revealed by Mr. Weiss.

a catalyzer. Carbon monoxide is adsorbed by metal oxides and readily oxidized at 100 deg. C., carbon monoxide is likewise adsorbed by charcoal, but its catalytic activity in promoting the oxidation of the monoxide is practically nil. The influence of one gas on the other is quite marked and was clearly demonstrated by Dewar (1904), who found, for example, that 1 cc. of charcoal adsorbed 18 volumes of O_2 but only 12 volumes of O_2 to which two volumes of H_2 had been added. Catalytic poisons do not necessarily cut down the adsorption of the essential reacting substances. The effect of catalyst poisons may be due in part to a reduction in the adsorption velocity. The addition of promoters to a catalyst renders it highly reactive. For example, a mixture containing 2.5 per cent Cr_2O_3 and 0.5 per cent CeO_2 with iron oxide increases the reactivity as compared with iron oxide alone manyfold. The addition of Cu to Ni catalyst in the hydrogenation of oils increases the ruggedness of the catalytic agent and renders it less sensitive to poisons. Further investigations are needed.

DISCUSSION

In discussing his own paper Dr TAYLOR felt that there was still considerable study and investigation necessary to clarify many of the peculiarities met with in catalytic reactions in general. Dr. Taylor took exception to the conclusion of N. K. CHANEY brought out in his paper on the "Activation of Carbon" (Wednesday's session), that there were two kinds of the same carbon, an active and an inactive one. Comparatively inert copper oxide could be rendered very active in oxidizing hydrogen by repeated alternate reduction and re-oxidation of the copper oxide. Are we justified in concluding that there are two modifications of copper oxide, an active and an inactive one? Is it not merely a question of "degree" of activity?

Dr. S. C. LIND of Golden, Colorado, maintained that there was really only one definition for catalytic poisons: "Any substance which has an inhibiting effect upon the velocity of the reaction." In the case of the formation of hydrobromic acid from its elements he had been able to show definitely that the walls of the vessel (glass) do not affect the velocity of the reaction and that the inhibitive effect of HBr was solely in the gas phase. The reaction was very likely a pure heterogeneous one. Perhaps the best interpretation of photochemical reactions is that proposed by Nernst about two years ago. His conclusions are based on good thermodynamic grounds. He assumes, for example, in the case of the reaction $H_2 + Cl_2 = 2HCl$ that light dissociates the Cl molecule (or H molecule) into its atoms and that the atomic Cl then reacts somewhat as follows:

and then

The thermal data fit in splendidly. It can further be shown that the reaction comes to a standstill upon

the removal of the source of radiant energy. Under the influence of Ra rays the amount of HCl is proportional to the extent of ionization.

Professor ANDREWS of Purdue University, commenting on Dr. LIND's remarks, was of the opinion that *all* reactions might be considered photochemical reactions and that each molecule required for its activation certain definite rays.

Dr. C. L. PARSONS of Washington referred to Patrick's highly adsorptive silica gel and suggested that we might consider two modifications of silica, an active and an inactive one. He furthermore stated that it seemed very hard to believe that adsorption by platinum took place in the case of the oxidation of NH_3 , since the velocity of the gases through the gauze was at the rate of 40 cu.ft. per min. and the gauze was at a temperature of 1025 deg.

Dr. FINK in reply gave a brief account of the experiments he had carried out in 1905 with a view of determining the time required to form the adsorption film of SO_3 on Pt in the contact process and emphasized the fact that the film was formed the instant the SO_3 came into contact with the platinum; in other words, the film-forming velocity was found to be practically infinite.

Dr. TAYLOR cited the reaction N_2-N_3 , that is, the formation of active nitrogen, and described an experiment which showed rather conclusively that the velocity of adsorption of N_3 by copper oxide was exceedingly great.

Dr. C. HERING of Philadelphia referred to his experiments on the melting of steel under water.³ His experiments demonstrated that a gaseous film formed over the surface of the iron cathode during the high current density electrolysis in dilute sulphuric acid. The real cathode seemed to be the enveloping gaseous film and not the metal.

THERMAL PROBLEM IN ORGANIC CONTACT CATALYSIS

Dr. W. J. HUFF of Pittsburgh then read his paper on "The Thermal Problem in Organic Contact Catalysis."

Dr. Huff carefully reviewed the most important organic catalytic reactions. He subdivided them into three distinct classes: (1) Those that were decidedly exothermic; (2) those that were decidedly endothermic, and (3) those that evolved or absorbed very little heat. A series of examples were cited, such as Rittman's process for the cracking of petroleum, the splitting of ethyl alcohol into ethylene and water, the commercial synthesis of formaldehyde in presence of platinum or copper, the formation of phthalic anhydride from naphthalene in presence of vanadium or molybdenum oxide at temperatures of about 500 deg. C. In future developments of organic contact catalysis more stress ought to be laid on the heats of reactions. With the aid of the thermal factors conditions under which reactions are to take place can be more intelligently chosen.

³ *Trans., Am. Electrochem. Soc.*, Vol. 30, p. 350.

The last paper of the morning session was presented by Mr. F. C. ZEISBERG of the DuPont Company on "The Thermal Problem in the Contact Process of Sulphuric Acid Manufacture."

Mr. Zeisberg outlined the underlying principles of the contact process and reviewed the work of Rudolph Knietsch, Hasenbach, Herreshoff, Ferguson and others. At present the principle most used is conversion in steps, usually in a tower-like converter containing several trays of catalyst alternating with large empty spaces in which the gas may mix before passing into the next catalyst layer. This empty space may contain cooling tubes, usually those of a heat-exchanger used to preheat the cold burner gas, or the walls thereof may be equipped to radiate heat. One large manufacturer uses the heat exchanger principle, with the walls of the converter well insulated, another uses a converter the walls of which can be insulated to a variable degree, so that the excess heat is dissipated by radiation.

Either type of converter is quite satisfactory under present conditions. The arrangement of several trays affords the opportunity of varying the concentration and amount of catalyst in each tray, by which means alone a considerable control over the heat development may be attained. The alternation of trays and mixing chambers permits an equalization of temperature which cannot help but be beneficial, for undoubtedly hot spots develop in each tray, due to easier gas passage at some points or accidental accumulation of excessive platinum in spots, and the gas coming from such a hot spot is over-heated and not completely converted. By mixing with the larger body of cooler gas coming from the same tray, before passing on to the next tray, this overheating is corrected.

Some actual figures taken from a five-tray converter not fitted with a heat exchanger which are representative of good operation are:

	Deg. C
Entrance gas.....	385
Exit from first tray.....	540 — 560
Exit from second tray.....	520
Exit from third tray.....	500
Exit from fourth tray.....	450
Exit from fifth tray.....	385

With these temperatures about 60 per cent of the SO_2 is converted in the first section, the total conversion running a little over 96 per cent.

While this style of converter, as has been mentioned above, is sufficiently satisfactory under present conditions, it is not at all certain to continue so. Very recently it has become evident that liquid SO_2 recovered from smelter fumes may be used as the source of sulphur in the contact process, instead of pyrites or brimstone. If this is done 9.5 per cent of SO_2 may be present in the entrance gas, instead of the 7 per cent when brimstone is burned, without having less than the 2 mols. of O_2 per mol. of SO_2 present which are recommended by Knietsch.

This richer entrance gas will result in higher temperatures in the converter, which may or may not be capable of being satisfactorily handled as at present.

Consequently, though the problem of the disposal of heat in this particular reaction seems to have been fairly well solved at present, there is no certainty that it will remain solved, and the chemical engineer will probably have ample opportunity to continue to exercise his ingenuity on this problem in the future.

REACTIVITY AND ADSORPTION IN HETEROGENOUS CATALYSIS

The symposium on catalysis was continued in the afternoon. A paper was presented by Dr. ERIC K. RIDEAL of the University of Illinois on "Reactivity and Adsorption in Heterogenous Catalysis."

Dr. Rideal pointed out that the mechanism of heterogenous catalysis involved two separate investigations: (1) In what way does the medium in juxtaposition to the catalyst differ from that in the free space? and (2) By what mechanism is the reaction velocity increased or decreased by this alteration in the state of the medium? The conception that adsorption is the primary action in all cases of heterogenous catalysis is the viewpoint now generally adopted. Surface adsorption appears to be an instantaneous reaction, whereas intra-solid diffusion is an extremely slow process. Catalytic activity is proportional to the area of the catalytic material employed. Patrick's silica gel, which while possessing powerful adsorbing qualities and having an immense superficial area (2,500,000 sq. cm. per g.) is catalytically inert for most reactions. Three theories of the modus operandi of contact catalysis have been advanced: (1) That of Fink and Bodenstein (1907), according to which every molecule penetrating the adsorbed layer and diffusing to the catalyst reacts; (2) the single layer theory of Harkins and Langmuir (1917), according to which only those molecules of the reactants undergo chemical combination which strike the catalyst in juxtaposition to one another, and (3) the theory of Lewis, according to which we must assume that only those molecules which strike the catalyst with a certain initial energy content are capable of reacting with the catalyst to form an adsorption compound, and of these only those which become attached in juxtaposition to one another.

DISCUSSION OF DR. RIDEAL'S PAPER

In the discussion of Dr. Rideal's paper Dr. FINK referred to his actual measurements of the thickness of the adsorbed SO_2 film and that he had found that this was one molecule thick. However there seems no necessity of quibbling over the point as to whether the film was one or more molecules thick. Furthermore, the velocity of a contact catalytic reaction is not always dependent upon the diffusion velocity of the reacting gases through the adsorbed film, but may be determined by the chemical reaction. For example, in the case of the dissociation of SbH_3 on antimony (catalyst), the hydride is instantly adsorbed but slowly decomposed. The large temperature coefficient of the reaction substantiates this view.

Structure of Electrodeposited Metals

The final session was devoted to papers on plating and organic electrochemistry. Mr. WILLIAM BLUM of the Bureau of Standards reported at length on "The Structure of Electrodeposited Metals." Mr. Blum based his experiments on Profesor Bancroft's six axioms:

1. Bad deposits are due to excessive admixture of some compound or to excessively large crystals.

2. Excessive admixture of any compound can be eliminated by changing the conditions so that the compound cannot precipitate.

3. Increasing the current density, increasing the potential difference at the cathode, or lowering the temperature, decreases the size of the crystals.

4. The crystal size is decreased when there are present, at the cathode surface, substances which are adsorbed by the deposited metal.

5. If a given solution will give a good deposit at any current density, it will give a good deposit at any higher current density, provided the conditions at the cathode surface are kept constant.

6. Treeing is facilitated by a high potential drop through the solution and by conditions favorable to the formation of large crystals.

Experiments were conducted with solutions of zinc, copper and nickel, and it was found that the axioms mentioned are applicable over a very wide range of conditions.

DISCUSSION OF THE PAPER

In the discussion of the paper Dr. F. C. MATHERS commented on the importance of addition agents. He showed the members smooth deposits of silver obtained from silver nitrate solutions with tartaric acid as addition agent; on the other hand, substituting pyrogalllic acid for the tartaric acid produced dark, poor deposits of silver. Similarly, black deposits of silver were obtained in the presence of ferric salts. A chloride solution of tin produced the familiar crystalline deposit, whereas sulphate bath produced heavy smooth deposits. Glue is a very poor addition agent for antimony, but aloin and clove oil gave rise to a splendid polished surface of antimony. Dr. Bancroft suggested that further study ought to be made why sulphate baths produce good deposits of tin and chloride deposits poor ones. Mr. Blum added that in the case of the sulphate bath colloidal tin oxide was present, and this might be looked upon as an "addition agent."

Lead Plating From Fluoborate Solutions

The second paper was on "Lead Plating From Fluoborate Solutions," by Messrs. W. BLUM, LISCOMB, JENKS and BAILY. A large number of experiments were put through and it was found that

(1) By increasing the concentration of lead it is possible to use higher current densities without causing treeing of deposits.

(2) An increase in current density increases the tendency to treeing but produces finer grained de-

posits. Therefore the highest current density should be employed that will not produce appreciable treeing, since the finer grained deposits are more nearly impervious.

(3) By increasing the concentration of excess (or "free") fluoboric acid slightly finer grained deposits are produced, and there is somewhat less tendency to form trees. This is no doubt due in part to the decrease in lead ion concentration caused by the presence of the excess acid; and in part to the increase in conductivity and consequent decreased tendency to treeing.

(4) The presence of an excess of boric acid (above that required to combine with the hydrofluoric acid) has little effect upon the deposits. It is desirable, however, to have an excess of boric acid, since it reduces any tendency to decomposition of the fluoborate and consequent precipitation of lead fluoride sludge.

(5) By the addition of small amounts of glue there is less tendency for the deposit to form trees and the deposits of a given thickness are finer grained and more nearly impervious. In preliminary experiments it was found that sugar or glucose produces some improvement in the deposits but is not so satisfactory as glue.

(6) By increasing the temperature to 50 deg. C. (122 deg. F.) the deposits become somewhat more coarsely crystalline, and show no marked improvement over deposits produced at ordinary temperature.

(7) Mechanical agitation, for example by rotation of the anode or cathode, produces smoother and denser deposits than are obtained in still solutions. This is especially helpful where the deposit must be made from a restricted volume of solution, such as in the inside of a shell or other object. Air agitation has not been found satisfactory, as it produces spongy deposits.

It is interesting to note that in every case these observations and conclusions are in accord with Bancroft's "Axioms,"⁴ and furnish an excellent illustration of the value of these axioms as a guide for research in this field.

In view of the very marked effect of colloids and reducing agents in producing finer crystals and especially in reducing the tendency to treeing, a few experiments were carried out with lead acetate solutions, such as were employed by Glaser.⁵ Betts⁶ stated that he was unable to obtain in lead acetate solutions good deposits of lead even after the addition of reducing substances such as pyrogallol which had been employed by Glaser. This observation of Betts was confirmed by us when still solutions were employed, but if as suggested (but not clearly stated or emphasized) by Glaser, the solution was agitated, for example by rotating the cathode, a smooth, dense de-

⁴ *Trans.*, Amer. Electrochem. Soc. (1904), Vol. 6, p. 27, and (1913), Vol. 23, p. 266.

⁵ *Zeit. Electrochemie* (1901), Vol. 7, pp. 365 and 381.

⁶ *Lead Refining by Electrolysis*, p. 11. Wiley & Sons.

posit of lead was obtained in solutions containing

Lead acetate.....	g/L
Ammonium acetate.....	350
Pyrogallol.....	140
	1

An almost identical deposit was obtained in the same solution if glue (0.2 g/L.) was added in place of the pyrogallol. In acetate solutions containing no organic addition agent very poor spongy deposits were obtained even with rapid agitation.

These observations indicate that although lead fluoborate solutions are intrinsically superior to lead acetate solutions in that they yield good deposits without agitation or the use of addition agents, the effect of either colloidal or reducing substances is qualitatively the same and even more marked in lead acetate than in lead fluoborate solutions. It is therefore doubtful whether the use by Betts of such substances in lead fluoborate solutions in 1902 constituted a patentable novelty.

DISCUSSION

The paper was discussed by MESSRS. HOGABOOM, FINK and MATHERS. Dr. Mathers discussed the relative advantages of the fluoborate and the fluosilicate baths. Glue is a good addition agent in either of these electrolytes, but in the perchlorate bath it is worthless. However, in the perchlorate bath oil of cloves is a splendid addition agent, and in the lead acetate bath aloin gives good deposits.

Commercial Possibilities in the Electrochemical Production of Organic Compounds

The final paper on the program was on the "Commercial Possibilities in the Electrochemical Production of Organic Compounds," by Dr. C. J. THATCHER of New York. Dr. Thatcher has been manufacturing for several years a series of organic chemicals by electrochemical processes. Among these chemicals worth noting are paramidophenol, hydroquinone and anthraquinone. Although the processes had been known to the Germans for several years, details were never published, and it was necessary to work out each process here step by step.

Dr. Thatcher records in his paper some of the underlying principles on which successful operation is based and points out the many advantages of electro-organic methods in comparison with older methods. It is usually cheaper to oxidize, reduce or substitute by electrolytic than by chemical means. With power at metropolitan rates it is one-tenth as cheap to oxidize electrolytically as it is by bichromate chemically. Dr. Thatcher discussed at length the application of catalytic reactions at the electrodes and referred briefly to his patented "electrofiltros" silica diaphragm, which has been in successful commercial operation since 1915. The complete paper will be published in a later issue.

Messrs. BANCROFT and FINK discussed the paper. A member of the Western Reserve Chemical Co. mentioned that his company is making a number of organic products electrochemically.

World's Production of the Principal Metals

Dr. J. B. UNPLEBY of the U. S. G. S., in a lecture given in Paris, France, stated that during 1913 the United States produced 39 per cent of the world's coal, 36 per cent iron, 56 per cent copper, 32 per cent zinc, 30 per cent silver, 17 per cent tungsten, 38 per cent molybdenum, 65 per cent oil, 95 per cent natural gas, 16 per cent arsenic, 48 per cent phosphates and 20 per cent salt. During the same year the Transvaal produced 41 per cent of the total gold, Russia 99 per cent of the platinum and 55 per cent of the manganese, Peru 76 per cent of the vanadium, Rhodesia 35 per cent of the chrome iron ore, Canada 85 per cent of the nickel, China 53 per cent of the arsenic, India 59 per cent of the mica, Spain 54 per cent of the pyrites and 31 per cent of the mercury, Italy 43 per cent of the sulphur, Germany 92 per cent of the potash, Chile 22 per cent of the nitrate, France 58 per cent of the bauxite, Malay Peninsula 40 per cent of the tin, Austria 74 per cent of the magnesite.

Proposed Extension of War Minerals Relief Act

Liberalization of the War Minerals Relief act is to be considered promptly by the Committee on Mines and Mining of the House of Representatives. The committee will consider a bill by Representative Garland, of Pennsylvania, the chairman of the Committee on Mines and Mining, which provides for the reimbursement of claimants who undertook the production of the minerals covered by the act in response to "any personal, written or published request or demand from any of the governmental agencies as mentioned in the Act." A considerable proportion of the claims which have been filed with the War Minerals Relief Commission have been denied as a result of the Attorney General's opinion to the effect that claims could be allowed only to those having received personal requests from the Government agencies. The bill also provides for a prorating of the appropriation in case it should be insufficient to pay all claims.

A. S. T. M. Standards Adopted in 1919

The American Society for Testing Materials has published the ten standards adopted by letter ballot on Sept. 1, 1919, on the following materials and tests:

- A 47-19. Malleable castings.
- B 19-19. Cartridge brass.
- B 20-19. Cartridge brass disks.
- B 21-19. Naval brass rods for structural purposes.
- B 27-19. Chemical analysis of manganese bronze.
- B 28-19. Chemical analysis of gun metal.
- C 12-19. Laying sewer pipe.
- D 56-19. Flash point of volatile paint thinners.
- D 55-19. Determination of apparent sp. gr. of sand, stone and slag screenings, and other fine non-bituminous highway materials.
- D 36-19. Determination of softening point of bituminous materials other than tar-products (ring and ball method).

Meeting of Technical Association of the Pulp and Paper Industry

Meeting Practically Restricted to Committee Reports—Report and Discussions on Principles and Practice Involved in Washing Unbleached Soda Pulp—Testing Material—Pulp Molds—Exhibition—Flotation of Pulp Liquor

IN ORDER to allow time for the members to attend the Exposition, the meeting was practically restricted to committee reports and excursions to the paper mill plant of Sears, Roebuck & Co. and the Forest Products Laboratory at Madison, Wis. The report of the committee on soda pulp, MARTIN L. GRIFFIN, chairman, was the dominating feature of the meeting.

Washing Unbleached Soda Pulp

The soda process, as it is called, is the oldest of the chemical processes for the disintegration of wood into pure wood fiber. The process consists in cooking the wood, under high pressure and heat, with a strong solution of caustic soda, which dissolves the intercellular matter and forms what is commonly called "black liquor," so named from its color. This liquor must be drained off and the pulp thoroughly washed to free it from these impure residues, especially if it is to be bleached to a good white color, as is the usual practice.

It is common knowledge that the soda used in cooking the wood may be recovered by evaporating this by-product liquor to a thick consistence and then incinerating it to a product of "black ash," from which the alkali, as carbonate, may be leached in form for re-use after treatment with lime. This in general has been the practice from the beginning.

Although the soda ash is the chief and only by-product which has hitherto been reclaimed, the black liquor contains the possibilities of others of great value.

The manufacture of soda pulp divides itself naturally into two important parts—namely, the production of the pulp, including preparation of the wood, the cooking of it, washing out the residues, bleaching and finishing and the reclaiming system, beginning with the washing of the pulp, then the evaporation of the black liquor, incinerating to black ash, leaching it and finally causticizing to produce the cooking liquor in its original form, thus completing the cycle.

The pulp is the primary product, but the reclaiming system involves more chemical problems and is of prime importance. No production of pulp of any kind by the soda process can be successfully carried on without the recovery of the alkali.

The washing of the pulp is the connecting link between these two primary operations. The pulp must be washed clean and as expeditiously as possible. At the same time the residual black liquor must be kept up to as high a concentration and as small a volume as possible consistent with economy, which will involve questions like the losses of soda, the consumption of steam for evaporation, the amount of coal used for the incinerators and the cost of plant and its maintenance.

It will be the object of this committee to indicate the most advantageous means and procedure for accomplishing these results.

With the exception of the diffusion system of closed tanks in general use in the sulphate mills, it is cus-

tomary to drain and wash the pulp in open tanks having a false bottom of perforated sheet metal or a system of perforated piping.

MINIMUM DILUTION OF BLACK LIQUOR

The primary object aimed at is to preserve the original volume and strength of the black liquor contained in the digester with as little dilution as possible. The ideal, from this viewpoint, would be to squeeze or press the original liquor from the pulp after being blown, and then to wash out the remainder by "counter current" in a closed system. This is not practicable by any known process. We may, however, look for marked improvements in the future by the use of some form of continuous filter or hydro-extraction which shall displace the cumbersome system of tanks and piping by which the washing proceeds progressively with resulting progressively weaker liquors. The process in brief consists in draining the original black liquor from the pulp and beginning to wash with a weak liquor which will give a resultant liquor for the evaporation of about half the original strength. Sometimes two grades in strength of weak liquors are successively used. This will of necessity prolong the cleansing operation. The supply of these weak liquors is kept up from other tanks being progressively washed.

The question naturally arises, Why is the pulp not washed, battery style, in a closed system of diffusers? I can only give a speculative answer. The most probable reasons are that in the earlier years of the history of this process, such a system was not as well developed as it is today and the industry itself did not employ chemical engineers, and so a simple process of washing in open tanks requiring no particular skill or experience came into general use. There are other reasons which make the issue debatable.

Following the course of the process in order, it is important to make provision for the transmission of the contents of the digester into the washing tanks without loss of pulp or dilution of the liquor; the proper size of the tanks, the mechanical construction of the drainage false bottoms, the arrangement of the system of piping for adding the washing liquors, and drawing them off, the organization of the department, are all very important and have much to do with the rapid and efficient execution of this part of the process.

SHALLOW AND DEEP EXTRACTION TANKS

At this point I wish to discuss, by contrast, the extremes of two viewpoints of the process, neither of which is practicable, for the purpose of bringing out in the discussion what is the most practicable mean position. First, what must be involved in the process if we lay out an equipment of very shallow tanks, always bearing in mind our original premises, that resulting black liquors to the evaporators must be as concentrated and as small in volume as possible. We begin

the washing process and find that the strength of the outflowing liquor drops rapidly and it would require a series of weak washing liquors, differing by small degrees, to sustain a high strength of effluent. This would involve a complex system of tanks and piping, and control would be difficult. The only alternative would be to simplify the system of liquors, which would result in a larger volume of a weaker liquor going to the evaporator, with a probable loss of considerable alkali, too weak to be evaporated with economy. The only commendable thing about the shallow tank plan would be the rapidity with which the washing could be done.

The opposite extreme view would be the use of very deep tanks, wherein the depth itself would to a large degree be the equivalent of the closed system of counter current, battery style of tanks, the tanks themselves and their contents coalescing in the larger and deeper tank. The equivalent points of similarity are the opportunity to wash from the beginning with water, building up strength progressively throughout a longer course, still maintaining a fair degree of concentration as a resultant.

The use of a weak liquor followed by water would, of course, result in a much stronger effluent liquor. By such a procedure the whole process is prolonged and a larger plant and equipment become necessary.

The striking difference between the use of a deep tank and a system of small connected tanks is that in the former, all of the contents to the very bottom must be washed clean before any part of the pulp can be removed and the washing media can only reach the bottom strata by percolation from the very top, long after this part of the pulp is clean, and no pulp can be removed until washing of the whole is finished.

When using a closed system of small connected tanks, these tanks are operated in cycle order, each tank being cut out of the system, discharged, refilled and connected up again in its turn.

Thus we observe that there is a medium point between these extremes, depending upon local circumstances, where the best results may be obtained. By all of these processes, large amounts of heat are lost and the washing requires large volumes of hot water. The movement of the pulp is intermittent, thus necessitating considerable tank storage capacity at different stages of the process.

CONTINUOUS FILTRATION

Opposed to this old-time practice, I desire to present an entirely new view of washing soda pulp which I believe may become practical, and which I have referred to earlier in this paper.

With the rapid strides made during the last few years in mechanical continuous filtration, I believe it is quite within the range of possibility to filter and wash soda pulp with greater economy.

For many years moisture has been expelled by hydro-extractors and expression, by various devices. I am thinking of one type, consisting of a cage through which the wet material is forced by an auger-propeller squeezing out the fluid contents and delivering the mass relatively very dry. Such devices have been in use for many years for a large variety of products.

I believe it is possible and practicable to build these machines in multiple, tandem style, so as to effect a thorough and economical washing of pulp and maintain a high concentration of the liquor.

It is to be hoped that this brief exposé of some of the principles of washing soda pulp will lead to a discussion which will result in a better knowledge of the subject and give promise of more efficient and economical results in the future.

A discussion by Messrs. SPENCE, BACHE WIG, BEVERIDGE and others followed, which will be published in full in *Paper* with the other committee reports.

Testing Materials

WILLIAM H. GESELL gave the recommendations of the committee on the standard methods of testing materials used in the manufacture of paper. He especially urged that these methods be universally adopted throughout the industry.

Pulp Mold

DR. OTTO KRESS of the Forest Products Laboratory gave an interesting paper on ground wood pulp mold. Five million dollars' worth of pulp is now being lost due to this cause, to say nothing of the hundreds of millions of dollars' worth of engineering timber construction such as railway ties, shipway, pier and dock piling, telegraph poles, etc. The whole sum of \$20,000 has recently been appropriated by Congress to finance Dr. Kress's laboratory staff of nine men in their work on preservation of wood products.

Removing Pulp From Fourdrinier Waste Liquor

Among the exhibits on demonstration which were of especial interest to the paper manufactures, the Groch "Save-All" should be mentioned. It is a centrifugal flotation machine, the air drawn through the hollow shaft being disseminated through the liquor by impeller blades. Air bubbles accumulate on the fibers and balloon them up to the surface, where they are skimmed off. About six cents worth of pulp is obtained per ton of liquor. In the old practice, the greater part of this liquor was returned to be used with new pulp. This necessitated a great amount of pumping and dissatisfaction due to dirt accumulating in the system and producing an inferior quality of paper.

China's Foreign Trade for 1918

Regardless of internal disorganization, the foreign trade of China continues to show a satisfactory increase. The total foreign trade of the country for the year 1918 was the highest on record, being 1,040,776,113 haikwan taels, or approximately \$1,241,645,903, the increases being 28,325,709 haikwan taels and \$204,423,181. The greater value of the dollar increase is accounted for by the difference in the conversion rates, these being \$1.02 in 1917 as against \$1.193 for 1918.

Of the totals for 1918, Japan's share amounted to over 402,000,000 haikwan taels, or nearly \$498,000,000; and that of the United States, 136,000,000 haikwan taels, or nearly \$161,000,000.

Eliminating Hongkong (the trade of which port consists largely of transshipments from various foreign countries) with a percentage of 26.39, the United States comes second in the foreign trade of China with a percentage of 12.96. Therefore, after taking into consideration the shares of Japan, Hongkong and the United States in the foreign trade of China, aggregating over 79 per cent, there is left less than 21 per cent for the remainder of the world, of which the United Kingdom is credited with 7.17 per cent and France with 3.07 per cent.

Chicago Meeting, American Steel Treaters' Society

Convention of Men Practiced in the Art of Steel Treating—Exhibition of Materials, Instruments and Equipment Used in Case Hardening, Tempering, Steel Finishing, etc.

THE convention and exhibition of the American Steel Treaters' Society from Sept. 23 to 27, at the Seventh Regiment Armory, Chicago, was an endeavor to enact on a smaller scale the Chemical Exposition as carried out at the same time over at the Coliseum and the First Regiment Armory. Sixty-five exhibitors had booths, among which were exhibited various brands of steels varying in designation from yellow, red, blue, black, green, gold labels to stainless and so on. The several alloy companies had fine exhibits of vanadium, tungsten, chromium, nichrome, etc., in which they demonstrated the properties and uses of their products. The large nichrome annealing boxes were especially noteworthy. The larger instrument companies showed very complete lines of pyrometric, chemical, physical and mechanical equipment for laboratory use. Case hardening materials from R & H cyanide to special patented carbon preparations were all open to the inspection of the visitor. Oils for quenching, drawing, cleaning and rust prevention were shown in a wide variety.

ACTING OFFICERS ELECTED

The success of the society in its past year of existence has been largely due to the interest taken by its acting officers. These men were elected to continue in office for the coming year as follows:

- T. E. Barker, president.
- A. F. Boissoneau, first vice-president.
- E. J. Janitzky, second vice-president.
- A. G. Henry, secretary-treasurer.
- F. S. Crane, board of directors.
- F. C. Lau, board of directors.
- A. F. McFarland, board of directors.
- L. M. Rollins, board of directors.
- W. H. Eiseman, business manager.

PAPERS READ BEFORE THE SOCIETY

About forty papers were scheduled on the program during the twelve morning, afternoon and evening sessions. These will shortly appear in the journal of the society.

Mr. C. P. Berg in his paper on the relation of cutting tool steels to factory production emphasized the need of greater knowledge of steel among operators. He said:

"During the war the main object in view was to produce everything as quickly as possible; in other words, at high speed. In a great many factories this naturally created a good deal of misplaced enthusiasm, also resulting in their ordering practically every cutting tool made of high speed steel. These same people were also wondering why their shops had so much

trouble in producing work that would be up to specifications, as to finish and size on the inspector's bench. High speed steel is only intended for removing metal at a great speed and is therefore well suited for roughing tools of all kinds, but it will not keep a keen edge required for a high finish or close size, and should therefore be absolutely avoided for finishing tools. It takes a great deal more time for regrinding, trying to keep a keen edge on a high speed tool required for a good finish, than the time lost in reducing the speed of the machine suitable for a carbon tool. Production is decreased instead of increased by using high speed steels for finishing cuts.

"It is also a great deal better from a production standpoint to select only two or three kinds of high speed steels and the same number of carbon steels, instead of a great variety, for all metal cutting tools used in the factory.

"It is comparatively simple to make up standards for metal cutting and have the machine operators become used to them, when only a few kinds of steel are used."

Mr. Roy C. McKenna of the Vanadium Steel Co. gave a brief sketch of the methods used in the manufacture of high speed steels. On the whole he thought that a better product could be produced in the electric furnace than in the crucible, but that experienced crucible operators would be necessary to accomplish this. The average chemical composition was given as:

	Per Cent
Tungsten	16 to 20
Chromium	3½ to 5
Vanadium	½ to 1½
Carbon	0.62 to 0.77
Sulphur and Phosphorus	0.02 to 0.025

The presence of traces of manganese and silicon was not considered of any consequence, but copper and arsenic were not to be allowed under any circumstances. The physical treatment of the steel in rolling into bars was considered of fundamental importance, and because of this Mr. McKenna believed that the steel consumer should mainly depend on the producer in the matter of specifications and adapt himself to the brands of steel offered, which the producer offers in a reasonable variety.

C. N. Scott gave some elucidating information on the art of hardening the faces of drop hammer dies. Of the many other papers, that of Frank P. Fahy on magnetic steel should be especially noted. Mr. Fahy has performed a great amount of research work and had much of his data plotted which showed wide variations in the magnetic properties of the so-called electric steels.

British Scientists in Conference at Bournemouth

By JOHN B. C. KERSHAW

THE 1919 meeting of the British Association for the Advancement of Science was held at Bournemouth from Sept. 9 to 13, under ideal weather conditions. The meeting was well attended in view of the fact that Bournemouth is far removed from the busy manufacturing centers of the north, and that the problem of providing adequate traveling facilities and hotel accommodation had not been entirely solved by the local authorities. For the two previous years the meetings of the Association had been suspended for the first time in its history, owing to the difficulties caused by the war, and the 1919 Bournemouth meeting was therefore the first to be held under the new peace conditions.

For the benefit of those who are unacquainted with the aims and history of the Association it may be explained that it was founded at York in 1837 to promote and popularize the study of science and to extend its practical applications in the arts and industries, and that for over 80 years the members and associates have met annually in one of the leading cities or towns of the United Kingdom to hear and discuss addresses, reports and papers upon the various branches of scientific knowledge covered by the ten sections under which the work of the Association is now organized.

The Presidential Address

Sir Charles Parsons, F.R.S., the well-known engineer and designer of the Parsons steam turbine, is this year's president of the Association, and his address dealt chiefly with the services rendered by science and scientific men to the Allied Governments during the war and with the problems connected with the production of cheap power in the future, when the coal fields of the United Kingdom and of Europe will be approaching exhaustion.

With regard to the first portion of his address, the most interesting disclosure was that relating to the design and application of sound-ranging and listening devices, which have been used with great success both on land and sea during the war for localizing the exact position of batteries and submarines. The following extract from this portion of his address is of general interest:

DEVELOPMENT OF SOUND-RANGING DEVICES

"Probably the most interesting development during the war has been the extensive application of sound-listening devices for detecting and localizing the enemy. The Indian hunter puts his ear to the ground to listen for the sound of the footsteps of his enemy. So in modern warfare science has placed in the hands of the sailor and soldier elaborate instruments to aid the ear in the detection of noises transmitted through earth, water, air or ether, and also in some cases to record these sounds graphically or photograph-

ically, so that their character and the time of their occurrence may be tabulated.

"The sound-ranging apparatus developed by Professor Bragg and his son, by which the position of an enemy gun can be determined from electrically recorded times at which the sound-wave from the gun passes over a number of receiving-stations, has enabled our artillery to concentrate their fire on the enemy's guns, and often to destroy them.

"The French began experimenting in September, 1914, with methods of locating enemy guns by sound. The English section began work in October, 1915, adopting the French methods in the first instance. By the end of 1916 the whole front was covered, and sound-ranging began to play an important part in the location of enemy batteries. During 1917 locations by sound-ranging reached about 30,000 for the whole army, this number being greater than that given by any other means of location. A single good set of observations could be relied upon to give the position of an enemy gun to about 50 yd. at 7000 yd. range. It could also be carried on during considerable artillery activity."

NEW POSSIBLE SOURCES OF POWER

Concerning new possible sources of power apart from coal and water power, the harnessing of the latent molecular and atomic energy of matter and the tapping of the earth's internal heat are the only two sources that would appear at present within the bounds of practical realization; and upon the latter subject Sir Charles Parsons made the following suggestive remarks:

"*Bore-Holes.* In my address to Section B in 1904, I discussed the question of sinking a shaft to a depth of twelve miles, which is about ten times the depth of any shaft in existence. The estimated cost was £5,000,000, and the time required about 85 years.

"The method of cooling the air-locks to limit the barometric pressure on the miners and other precautions were described, and the project appeared feasible. One essential factor has, however, been queried by some persons. Would the rock at the great depth crush in and destroy the shaft? Subsequent to my address, I wrote a letter to *Nature*, suggesting that the question might be tested experimentally. Professor Frank D. Adams of McGill University, Montreal, acting on the suggestion, has since carried out exhaustive experiments, published in the *Journal of Geology* for February, 1912, showing that in limestone a depth of 15 miles is probably practicable, and that in granite a depth of 30 miles might be reached. When we consider that the estimated cost of sinking a shaft to a depth of 12 miles at present-day prices is not much more than the cost of one day of the war to Great Britain alone, the expense seems trivial as compared with the possible knowledge that might be gained by an investigation into this unexplored region of the earth. It might, indeed, prove of inestimable value to science, and also throw addi-

tional light on the internal constitution of the earth, in relation to minerals of high specific gravity.

"In Italy, at Lardarello, bore-holes have been sunk, which discharge large volumes of high-pressure steam, which is being utilized to generate about 10,000 hp. by turbines. At Solfatara, near Naples, a similar project is on foot to supply power to the great works in the district. It seems, indeed, probable that in volcanic regions a very large amount of power may be in the future obtained directly or indirectly by boring into the earth, and that the whole subject merits the most careful consideration."

HIS PLAN BOLD AND ORIGINAL

Although Sir Charles Parsons did not elaborate further his plan of obtaining power from the interior of the earth, the idea of constructing a deep shaft, and of then allowing water to flow in for the production of steam, i. e., using the earth as an immense natural high-pressure boiler, is distinctly bold and original, and probably more practicable than the late Sir William Ramsay's project of sealing up a coal mine and then generating a mixture of air- and water-gas *in situ*, by supplying air and water to the burning fuel. The greatest difficulty in the practical application of Sir Charles Parsons' plan in fact appears to be the time required to sink the bore-hole, which he estimates at 85 years, but surely with modern methods and machinery this could be reduced considerably. Since nature is already doing in Italy what Sir Charles Parsons is proposing to do upon a much larger scale, there is nothing inherently impossible in the idea, and therefore more may be heard of this plan of generating steam power by aid of the internal heat of the earth before the present generation is 20 years older.

Address of Prof. J. E. Petavel

The address of Professor J. E. Petavel, delivered before the members of the Engineering Section of the Association, was also devoted to the services rendered by engineers and scientists during the world war, but its most valuable portion related to the industrial and economic position of the various belligerent nations during the present reconstruction period.

Since the United States is now faced with many problems of this nature, the following extracts from this portion of the address will prove of interest to readers of CHEMICAL & METALLURGICAL ENGINEERING:

"The total remuneration received by a nation is measured by its production, and this law cannot be altered or affected by legislation or revolution. On the other hand, the share received by a class or an individual is capable of adjustment within certain limits. Thus any class may increase its remuneration either by increasing the total production, or by decreasing the remuneration received by the other classes. The capitalist who corners wheat, and the miner who corners coal, are examples of the latter method. No such limitations exist, however, with regard to the

face value of the wages paid; by act of Parliament all wages might be increased arbitrarily twentyfold, but as a result the cost of living would rise in a similar ratio.

"Incalculable harm has been done by ignorance and wilful misrepresentation. During a generation the working classes have been told, and have firmly believed, that they receive but a tithe of the value of their work, and that the bulk goes to swell the fortune of the capitalistic class. The actual facts, so far as engineering is concerned, will be found in the address of my predecessor in this chair. On an average in pre-war days the share of the capitalist was one-ninth that of the workman. The actual position with regard to coal is not known to all. For each ton raised 19s. 5 1/2 d. goes for labor, and a total of 2s. is paid as royalties, owners' profits and owners' compensation. It is obvious that the 13s. rise in the miner's wages cannot be paid out of profits and royalties amounting to a total of 2s., but the miner, who has been brought up to believe in the fabulous profits of the wicked duke, is quite ready to strike against the owners, the Government and the laws of arithmetic.

"The economic value of an individual depends exclusively on the nature, quality and quantity of his output, and his remuneration should correspond to his economic value. The rule is simple, its application would solve most of the problems which vex the present generation, but no scheme has yet been evolved to make its application possible.

PRESENT INDUSTRIAL SYSTEM A FAILURE

"There can be no doubt that in this respect our present system is a complete failure. It has been built up casually in the course of the industrial warfare of the last 20 years, and each side, regardless of consequences, has entrenched itself in any position won. The result is a system nearly perfect from the point of view of offence and defence, well arranged for mutual destruction, but, like the trenches in France, unsuitable for use in time of peace.

"Among the professional and business classes the remuneration is proportional to the skill and to the effort; a barrister, an engineer, or a merchant has neither minimum wage nor fixed maximum output, and, the vagaries of chance excepted, generally speaking he gets what he is worth. At the two extremes stand riches and starvation, and the economic world can offer no stronger motive forces than the allurements of the one, the fear of the other. There is no absolute reason why the workingman should not be offered the same incentives to hard work and progress, but up to the present most efforts have tended in the opposite direction. Any form of payment by results is viewed with indifference or distrust by the unions, and past experience with piece work explains that attitude. There has been a disposition for employers to make large individual earnings an excuse for cutting rates. Errors in rate-fixing may

easily arise and in certain cases special investigation might be necessary, but the advantages of high individual production are so great to both employer and employed that in all cases of doubt the higher rate should be maintained. In this connection the method of time-study, first developed by Taylor in America, and the various systems of payment by results which have been successfully applied deserve careful consideration.

FALSE DISTINCTION BETWEEN SKILLED AND UNSKILLED LABOR

"Another important but difficult subject is the distinction drawn between skilled and unskilled labor. The experience gained during the war has proved that many operations scheduled as skilled work could be effectively performed by women who had received only a few weeks special instruction. The oft-repeated demand for equal opportunity for all becomes a senseless parrot-cry, if it does not imply that an individual has the right to undertake better remunerated work if qualified to do so. It is a misconception which leads the skilled worker to believe that such a concession would reduce his earnings. Just as it is clear that, if laborers and skilled men were grouped together at a uniform wage, that wage would necessarily be lower than the present minimum for skilled work, so also the separation of tasks which require but a nominal period of training would increase the rate of remuneration available for the really skilled man.

INCREASED PRODUCTION THE PRESSING NEED

"I have drawn attention to some of the difficulties which must be solved if the country is to emerge from the present crisis prosperous or even solvent. There is little doubt that an elucidation is possible, but it can be evolved only by the honest and intelligent collaboration of all parties concerned, a task rendered difficult or impossible by mutual distrust and class hatred. Class differences there are, and always will be; they exist as the result of breeding, education and environment, but they do not extend to the fundamental characteristics of humanity. Many dukes and many miners are lazy, most capitalists and most trade unionists are greedy; all men, with a few exceptions, are selfish. The war has shown that lazy, greedy and selfish men will die, or even work for their country in a great exigency, but there is a limit to and a reaction after any profound emotional stimulus, and the present unrest and dissatisfaction are but normal symptoms. A satisfactory economic system can be based only on natural human impulses, and of these the most fundamental is self-preservation, or, more generally, self-interest. Increased production is at the present moment the most pressing national need, but it will become effective only when for every man increased production becomes the talisman by which his paper wages can be turned to gold."

Meeting of the Societe de Chimie Industrielle

THE first meeting of the season of the New York Section of this society was held in Rumford Hall at the Chemists' Club, Friday, Oct. 3. The president, Dr. L. H. Baekeland, occupied the chair, and Mr. J. V. N. Dorr was elected treasurer to succeed Dr. George F. Kunz, who resigned.

Lieutenant René Engel, formerly of the French High Scientific Mission, and a councillor of the parent society in Paris, spoke on the fuel problem in Europe, and more particularly in France. He had spent a number of months in the Saar region, and said that the return to a normal state of output, even with the former Prussian government mines, is very slow. Owing to the destruction of French mines, the deficit in France will be greater this year than usual, despite the accessions of mineral territory. The production of Alsace-Lorraine for 1919 is estimated to be about 26,000,000 tons, of which local industries and requirements take 14,000,000. The peace-time production of the district is a little less than 14,000,000 tons, against consumption in the same region of 5,500,000 tons.

Mr. Engel expressed the belief that French mines can be made to yield considerably better returns by improved methods, provided the prejudices of the miners can be overcome. The present situation, pretty well throughout Europe, is bad. Men will not do a day's work under any conditions. An average of 1 1/2 tons per man per day has dropped down to 5/8 ton, while the average per man here is 3 tons. He followed with proposals for more economical uses of coal which are familiar to our readers. There are still technologists in France, he said, who oppose the use of coal powder on the ground that it is impracticable, citing an explosion in a cement works in 1913 as ground for their objection. The use of benzene for explosion engines is more general there than here. Good results have been obtained by mixtures with gasoline in ratios of from 1:1 to 1:3.

CHEMICAL WARFARE IN FRANCE

Lieutenant-Colonel J. Enrique Zanetti, Ph.D., assistant professor of chemistry, Columbia University, told of his experiences in chemical warfare in France. It may be recalled that, in an interview which we published with Brigadier-General Fries, who commanded the American Chemical Warfare Service in Europe, he referred to Colonel Zanetti as an officer of singular efficiency and competence. As liaison officer, the speaker said, he was appointed the official beggar from the French, and he doubted if the job of begging could be made more pleasant.

His first impressions of the French laboratories were those of surprise at their dinginess and lack of equipment. As a French professor explained to him, they could not with their love of tradition tear down their old buildings very well, and he proved this by

showing his balance room in an apartment 600 years old with walls five feet thick. Col. Zanetti soon concluded, however, that it calls for something more than a Ph.D. diploma and an up-to-date laboratory to get to work and obtain results.

When the war came upon them there was no liquid chlorine in France. Such as they had needed theretofore had been obtained from Germany, and at rates so low as to arouse suspicion that the Germans did not want to have the chlorine industry developed in a neighboring territory. In addition to remarkably low prices the liquid chlorine had been delivered to them f.o.b. at the French border. It took no little ingenuity to develop large production, especially as they were sorely deficient in electrical equipment. Any one having experience in chlorine manufacture will surely admit this, nevertheless within a year after the first chlorine attack upon the British, the French were turning out 30 tons daily of the liquefied gas and within one year nearly 50 tons. This amount was not enough and 1600 tons were shipped from the United States to France in 1918, making an extremely valuable contribution at an intensely critical period.

QUICK PRODUCTION OF PHOSGENE

Phosgene was scarcely used before the war, and suddenly it had to be made on a vast scale. This was quickly mastered by the French. The United States was too late and Great Britain was too slow. The French made 24 tons daily in five factories. The same may be said of mustard gas, of which at the time of the armistice from 20 to 25 tons per day were available from French establishments.

In other words, practically all the phosgene and mustard that was shot over the German lines was made in France. The mustard and phosgene from the United States arrived too late, although we shipped great quantities of both. Only the armistice saved the Germans from what would have been a deluge of gas.

The difference between the French and American methods was that while the French took their problems as war-time propositions and used any kind of apparatus that would serve to achieve production in moderate sized units, with speed as their watchword, we went at it as an industrial proposition with quantity production as our slogan. Thus the French synthesized, manufactured and fired mustard within six months. It reached the enemy in time. The German High Command had talked freely of the terrors of this gas, and of the desolation it caused among the Allies. When they got it back the German troops remembered these things, and their morale was anything but improved by the retaliation.

Another point made was the astuteness with which political troubles were met by the French authorities. Every inventor in France, nearly, invented a gas mask, and back of each inventor was a member of the Chamber of Deputies who was resolved to save the country by that particular device, otherwise not only he, but the whole world, would know the reason

why! It was soon discovered, as in this country, that not one in ten thousand of the inventions of these self-appointed geniuses was worth looking into. So the Chief of the Department built a gas room that would hold fifty men. The inventors were invited in groups each one to wear his own mask, to enter and to remain in this room for ten minutes. As soon as the door was closed chlorine was turned on to a concentration equivalent to that met in the field. At the end of three minutes there was seldom more than a few left, and it was rare indeed that any one remained there through the fourth or fifth minute. This procedure invariably satisfied the inventor and silenced the Deputy. There was no argument, and the test was conclusive.

A TEXAN'S SERVICE TO ENGLAND

Mr. Clinton P. Townsend of Washington, consultant of the Bureau of Ordnance, related some of his experiences in England, more particularly in connection with that country's war chemistry and the production of munitions. He sought first Mr. Kenneth Quinan, a Texan by birth, who had lived for the score of years preceding 1914 as a chemical engineer in South Africa, engaged chiefly in setting up explosive works. Five hours after Great Britain entered the war Mr. Quinan was en route for England, where he was made head of the Department of Explosive Supply in the chemical service. In contrast to the secrecy which we in this country maintained, Mr. Quinan showed him a map of England, with every factory spotted off, and a record of what each was making, how it was making it, and the quantity produced. The main thought in the English munition works seemed to be of maximum efficiency. No one appeared to be hurried, but in every factory there was a chart showing how that plant was doing, and comparisons were made with all other works engaged in similar production. Mr. Townsend said that the 5000 Welsh girls who worked in a plant that he examined showed the same interest in the competitive returns that an American crowd displays in watching the bulletins of a ball game in a world series. This whole spirit, he said, was due to the remarkable organizing ability of one man, and he was Kenneth Quinan. He concluded with some personal notes in regard to Mr. Quinan's methods. By 1914 he had already designed and built about 500 chemical plants, so that he had had abundant opportunity to put his theories into practice.

Given a problem, his first step is to get all the information available about the reactions, including a careful investigation into the endothermic or exothermic nature of each. Then, along with the study of the nature of the materials and of the various kinds of apparatus that are available, he prepares a heat flow sheet as a primary requirement before making plans, and a complete allocation of heat is made before any apparatus is designed. Semi-commercial plants do not appeal to him as a rule; they seem more frequently to be mere excuses for shiftless laboratory work.

Personal

Dr. R. A. BAKER, recently Major, Chemical Warfare Service, and Commandant of the U. S. Gas School at Camp Kendrick, N. J., and prior to that assistant professor of inorganic chemistry at the University of Minnesota, has been appointed professor of general and inorganic chemistry at Syracuse University, Syracuse, N. Y.

Mr. ALFRED C. CHAMBERS, who recently resigned his position as chief of the Quality of Water Division, Water Resources Branch of the Geological Survey, is now connected with the Youngstown Sheet & Tube Co., Youngstown, Ohio, as chemist in its laboratory.

Prof. J. B. CHURCHILL, formerly professor of chemistry in the University of Pennsylvania, has been appointed technical chemical director of the British-American Chemical Corporation.

Mr. J. H. DEPPER of the Metal & Thermit Corp. has been elected a vice-president of the American Welding Society, New York.

Mr. PAUL A. KEENE, who has been engaged in Government nitrogen fixation, has accepted a position with the Solvay Process Co. in its laboratory in Syracuse, N. Y.

Mr. MILO W. KREJCI has been appointed superintendent of the International Lead Products Co. and will have charge of the operations at the new plant at East Chicago, Indiana.

Mr. EDWIN LUDLOW has opened an office as consulting engineer at 149 Broadway, New York City.

Mr. WALTER F. MEISTER, formerly chief chemist for the Eagle-Picher Lead Co., is now chief chemist for the Collinsville Zinc Corp., Collinsville, Ill.

Mr. JOSEPH E. PLUMSTEAD has accepted the position of assistant superintendent of the Delaware Mills plant of the Jessup & Moore Paper Co. and consulting chemist for its five pulp and paper plants. He was formerly doing development work for the Celluloid Co., Newark, N. J.

Prof. MERLE RANDALL has returned to the University of California, Berkeley, Calif., after having spent the summer as research chemist in the laboratories of the Experimental Kelp-Potash Plant of the U. S. Department of Agriculture, Summerland, Calif.

Mr. C. M. SALLS, formerly with Canadian Explosives, Ltd., is now chemist with the Canada Starch Co. of Cardinal, Ontario, Can., which is the Canadian branch of the Corn Products Refining Co.

Mr. BERNARD H. SMITH, formerly chemist and superintendent of the Baker Extract Co., Springfield, Mass., has accepted a similar position with Garrett & Co., Brooklyn, N. Y.

Dr. JOHN E. TEEPLE, 50 East 41st Street, New York City, has been elected treasurer of the American Chemical Society to fill the unexpired term of Dr. E. G. Love.

Mr. P. F. WILLIS, president of the Henderson-Willis Welding & Cutting Co., has been elected a director of the American Welding Society.

of useful data concerning over 7000 products in daily use in the chemical industry. Its appearance will therefore be welcomed not only by the busy chemist but by exporters and importers, brokers, purchasing agents, financial houses and others seeking reliable information free from commercially irrelevant scientific detail.

In addition to the name of the commodity, the following data are given wherever possible: Formula, color and properties, constants (boiling point, melting point, specific gravity, solubilities, etc.), derivation (brief statement of process of manufacture), method of purification, grades, containers, uses, fire hazard and railroad shipping regulations.

The book is exceptionally free from typographical errors. Inconsistencies of minor importance will be noted occasionally, for example on pages 94 and 95. On page 94 we find that barium hydroxide is prepared "by dissolving barium oxide in water and subsequent crystallization," while on page 95 it is stated that barium oxide is made "by calcining barium hydroxide." Also, on page 196 under dimethylglyoxime method *c*: "Nitrosomethylethyl ketone is prepared from methyl ethyl ketone, amyl alcohol and hydrochloric acid * * * Obviously, amyl nitrite should be read in place of amyl alcohol. Such minor errors do not, however, detract from the value of the book (as it is not intended to be a handbook of chemical manufacturing methods) but serve rather to emphasize the difficulties which confronted the editors in their task of sifting such a large mass of data. They are to be heartily congratulated upon the fruit of their endeavors.

ALAN G. WIKOFF.

CHEMISTS' FIRST-AID TREATMENT. By Paul Nicholas Leech. 11 pages. Chicago: The Chicago Chemical Bulletin.

The author was selected by the *Bulletin* to write this pamphlet as a chemist who was in touch with medicine. The subjects are covered under chapters, as follows:

- I. The Emergency Treatment of Burns.
- II. The Emergency Treatment of Abrasions, Bruises, etc.
- III. The Emergency Treatment of Internal Conditions.

Addenda. Poisoning.

The work is covered in a more comprehensive manner than by a simple antidote list and should be very useful to laboratory and works operators.

CHESTER H. JONES.

Current Market Reports

The Non-Ferrous Metal Market

Monday, Oct. 20.—The non-ferrous markets have reflected the effects of the steel strike, with the result that present quotations are practically nominal and in spite of this are advancing.

Aluminum.—Transactions are largely made on direct contract between producer and consumers. The open market is not active; 98-99 per cent ingots are quoted at 32-33c. per lb; cast scrap, 24½-25½c.; sheet scrap, 23-24c.; and clippings, 26½-28c.

Antimony.—The market is easy; spot wholesale is quoted at 8¼c. and futures at 8c. lb. Small job lots, 9c. lb.

Copper.—Copper is practically nominal with sellers waiting for the demand to develop.

Copper, lake	22¼	— 23½
Copper, electrolytic	22	— 22½
Copper sheets, hot-rolled	22½	— 23½
Copper sheets, cold-rolled	35	—
Copper bottoms	41½	—
Copper rods	25	—
Copper wire	26	—
High brass wire & sheets	26	—
High brass rods	26½	—
Low brass wire & sheets	30½	—
Low brass rods	31	—
Brazed brass tubing	30	—
Brazed bronze tubing	44½	—
Seamless copper tubing	37½	—
Seamless bronze tubing	40	—
Seamless brass tubing	36	—
Scrap, heavy mach. comp.	17	— 19
Scrap, heavy and wire	17	— 18
Scrap, light and bottoms	15	— 16
Scrap, heavy, cut and crutible	18½	— 20
Scrap brass, heavy	10	— 11
Scrap brass, casting	12	— 13
Scrap brass, light	9	— 10
Scrap, No. 1 clean brass turnings	10	— 10½
Scrap, No. 1 comp. turnings	15	— 16½

Book Reviews

THE CONDENSED CHEMICAL DICTIONARY. Compiled by the editorial staff of the *Chemical Engineering Catalog*. 525 pages. New York, The Chemical Catalog Co., Inc.

The difficulties encountered in attempting to obtain quickly data on commodities selected at random from the wide range of chemicals having commercial applications are perhaps fully realized only by those who have been called upon to obtain such information in reply to miscellaneous inquiries. Often a search through the standard books of reference fails, and recourse must be had to text books, periodicals and other literature dealing with the subject. Such a process is tedious even to those trained in this work; and to those business men who require chemical facts but have not had a chemical training—impossible.

The Condensed Chemical Dictionary represents a compilation from the sources mentioned above (and many others)

Lead:—The market for lead has continued to strengthen. East St. Louis now quotes at 6.3c, and New York 6½c. lb.

Tin:—Incoming tin continues to be tied up in the port due to the strike of the longshoremen. Small stocks are being held at 57c. lb.

Zinc:—Zinc continues at 7.65c. both in New York and St. Louis.

OTHER METALS

Bismuth	lb.	\$2.95 —	
Cadmium	lb.	1.50 —	1.75
Cobalt	lb.	2.50 —	3.50
Magnesium	lb.	1.75 —	2.10
Mercury	75 lb.	80.00 —	95.00
Nickel	lb.	41 —	45
Iridium	lb.	175.00 —	
Palladium	oz.	115.00 —	120.00
Platinum	oz.	130.00 —	
Silver	oz.	1.18½ —	

The Iron and Steel Market

The iron and steel strike has been waning since last report, but at a very slow rate. This review covers the fourth week of the strike. At the inception the appraisal of the manufacturers was that if the strike should seriously cripple the majority of the producing districts it would probably be a long drawn out affair, a matter of say two to four months, but that if some districts, including the Pittsburgh district, could be kept operating moderately well the strike would play out in a very few weeks, say from two to four weeks.

The strike started out by agreeing with the second alternative, since it left Western Pennsylvania in fairly good operating condition, and did not curtail production in the whole industry by as much as 50 per cent, but now, after four weeks, it is not receding as rapidly as it was expected to do with such circumstances. The number of men at work in the Pittsburgh district increases day by day, but even with the spectacle of nearly all the mills running in good shape some strikers still stay out.

It was problematical when there would be any considerable return of men in the strike districts where the stoppage of production was complete, and where the breaks would first occur. The first district to begin resumption proves to be the Mahoning Valley, but instead of the beginning marking a stampede the men are returning to work very slowly. In that valley there are 27 blast-furnaces, of which 22 were active just before the strike, and all were closed by the end of the second day. Now only about five are operating, and it is understood they are not in all cases approaching normal tonnage. At least three of the four large open-hearth producers in Youngstown are producing a little steel, having only a few furnaces operating. So far as known only one bessemer converter is operating.

TONNAGE OUTPUTS

The ingot production report for September has not been issued yet, but as the strike began on the 22d the report would not be illuminating. The August report showed production of steel ingots in the industry as a whole at the rate of about 39,100,000 gross tons a year, and except when, as during the war, there is an abnormal distribution of steel among the different finished lines, the finished rolled steel output runs at about 76 per cent of the ingot tonnage. With a trifling increase over the August rate, there would have been a rate just before the strike of about 2,500,000 gross tons of finished rolled steel a month. At its maximum the curtailment was more than 40 per cent, but hardly as much as 50 per cent, and at the end of the first 30 days of the strike the production rate is about 60 per cent. Thus the first month of the strike witnessed a loss in output between 1,000,000 and 1,250,000 gross tons. Should a quick return of men to work begin in the next week or two output would require several weeks for even an approximate return to normal, and nearly a million tons more would be lost after the first month, so that the minimum loss in tonnage may be set at 2,000,000 tons. The maximum, even if the strike continues to wane only slowly, as at present, would be unlikely to exceed 3,000,000 tons.

The steel market has of course been very quiet. Mills are booking some contract tonnage from regular customers, merely as a routine matter. There is no mill in position to take on orders for early deliveries. Consumers continue to

show the utmost patience in the matter of deliveries, assuring producers that while they wish to know what deliveries may be expected they are anxious not to embarrass the mills by making requests for deliveries.

Stocks in consumers' hands seem to be holding out fairly well, and probably somewhat better than was expected. It is quite certain that there were no large stocks anywhere, and that the production before the strike was passing directly into consumption.

PIG IRON

There has been active buying of pig iron in the East, where some consumers are short on account of the strike curtailing output at Buffalo, while the eastern Pennsylvania and Virginia furnaces are not affected by the strike. No. 2 foundry delivered Philadelphia, \$30.60 in September, is now up to \$32.10. The Pittsburgh and valley markets are unchanged and show only a moderate demand, merchant pig iron production in that section being very slightly affected by the strike.

The Chemical Market

New York, October 20, 1919.

The delays in making deliveries and the holding up of export business, brought about by the various labor disputes, have reduced inquiries on many commodities and tied up business to a great extent. Manufacturers of coal-tar products are bending their efforts toward meeting all contracts, and their interest in the spot market is therefore small. Good demand and none too abundant supplies, with the probable return of the speculative element, combine to make a bull market on vegetable oils. Why linseed oil should jump to \$1.81 per gal. for spot goods is unaccountable, considering that England has on hand abundant supplies of this oil. With the harbor strike in full force, the naval stores market was in a strong position at the beginning of the week, but it weakened at the close when shipping conditions improved. There are no spot supplies of spirits of turpentine, although stocks of rosins are fair.

HEAVY CHEMICALS

Resulting from the recently noted scarcity of *sulphuric acid*, the 66 deg. variety is being held at higher figures in some quarters. Some dealers are holding it at \$18 to \$20 per ton in tank cars, whereas formerly it could be bought as low as \$15 per ton. Manufacturers in the Middle West are said to be asking \$22.50 per ton, f.o.b. works. Former quotations of \$12 to \$13 per ton on the 60 deg. are strictly maintained.

Sodium nitrite relaxed slightly during the past week and can now be bought around 13 to 14c. per lb., comparing with the previous quotation of 15 to 18c. *Sodium bichromate*, however, shows the opposite tendency and is firmer at an increase of ½c. over the minimum quotation of 12c. per lb. of last week.

Attributable to depleted supplies resulting from England's inability to make shipments is the higher minimum offering price of *caustic soda* by second hands of \$3.30 per cwt. One sale of 600 tons at \$1.85 per cwt. at works was reported. Several inquiries regarding contracts on this commodity and *soda ash* have been received, but manufacturers in the face of present conditions are in no hurry to take them up. A few small contracts for *zinc oxide*, *lithopone* and *sodium silicate* are the only ones reported as signed recently. Spot *soda ash* is in strong demand, and the dense is difficult to get at \$2.25 per cwt. ex-store.

The continued scarcity has increased the minimum price of *aqua ammonia* another 1c. per lb., 9c. now being the lowest mark.

Sal ammoniac is going to be very scarce owing to the present shortage of ammonia and *muratic acid*, the latter being in large request from color manufacturers. Manufacturers of *sal ammoniac* are usually able to meet English quotations on this chemical, but with jobbers at present quoting 11½c. per lb. for English goods, they are out of the market.

Although *sodium prussiate*, yellow, afloat from England is being offered at 24c. per lb., spot material holds unchanged at 26-27c.

Paranitraniline.....	lb.	0.95-0.95	1.10-1.10
Para-nitro-toluenol.....	lb.	1.35-1.35	1.50-1.50
Paraphenylenediamine.....	lb.	2.50-2.50	4.00-4.00
Paratoluidine.....	lb.	1.50-1.50	2.00-2.00
Phthalic anhydride.....	lb.	1.50-1.50	2.00-2.00
Phenol, U. S. P., drums (deat.), (240 lb.).....	lb.	2.00-2.00	2.2-2.2
Pyridin.....	gal.	2.50-2.50	3.75-3.75
Resorcinol, technical.....	lb.	6.50-6.50	6.75-6.75
Resorcinol, pure.....	lb.	6.50-6.50	6.75-6.75
Salicylic acid, tech., in bbls. (110 lb.).....	lb.	3.8-3.8	4.5-4.5
Salicylic acid, U. S. P.....	lb.	4.5-4.5	5.0-5.0
Salol.....	lb.	1.50-1.50	2.00-2.00
Solvent naphtha, water-white, in drums, 100 gal. gal.....	gal.	2.0-2.0	2.7-2.7
Solvent naphtha, crude, heavy, in drums, 100 gal. gal.....	gal.	1.8-1.8	2.4-2.4
Sulphanilic acid, crude.....	lb.	2.5-2.5	3.1-3.1

Tolidine.....lb.	\$1.70	—	\$2.50
Toluidine, mixed.....gal.	.45	—	.55
Toluol, in tank cars.....gal.	.26	—	.30
Toluol, in drums.....gal.	.27	—	.30
Xylidine, drums, 100 gal.....lb.	.44	—	.50
Xylol, pure, in drums.....gal.	.37	—	.45
Xylol, pure, in tank cars.....gal.	.35	—	.45
Xylol, commercial, in drums, 100 gal.....gal.	.23	—	.27
Xylol, commercial, in tank cars.....gal.	.22	—	.25

Waxes

Prices based on original packages in large quantities.

Beezwax, natural crude, yellow.....lb.	\$0.42	—	\$0.44
Beezwax, refined, yellow.....lb.	.46	—	.48
Beezwax, white pure.....lb.	.66	—	.68
Carnauba, No. 1.....lb.	.67	—	.88
Carnauba, No. 2 regular.....lb.	.64	—	.80
Carnauba, No. 3, North Country.....lb.	.48	—	.50
Japan.....lb.	.18	—	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.....lb.	.06	—	.06
Paraffine waxes, crude, scale 124-126 m.p.....lb.	.06	—	.06
Paraffine waxes, refined, 118-120 m.p.....lb.	.09	—	.08
Paraffine waxes, refined, 126-130 m.p.....lb.	.09	—	.09
Paraffine waxes, refined, 133-135 m.p.....lb.	.104	—	.114
Paraffine waxes, refined, 135-137 m.p.....lb.	.12	—	.134
Stearic acid, single pressed.....lb.	.28	—	.28
Stearic acid, double pressed.....lb.	.27	—	.29
Stearic acid, triple pressed.....lb.	.31	—	.33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oil in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....gal.	\$1.15		
Pine oil, pure, dest. dist.....gal.	1.00		
Pine tar oil, ref., sp. gr. 1.025-1.035.....gal.	.45		
Pine tar oil, crude, sp. gr. 1.035 tank cars f.o. Jacksonville, Fla.....gal.	.34		
Pine tar oil, double ref., sp. gr. 0.965-0.990.....gal.	.65		
Pine tar, ref., thio, sp. gr. 1.080-1.060.....gal.	.38		
Turpentine, crude, sp. gr. 0.900-0.970.....gal.	.85		
Hardwood oil, 50 gal. Mich., sp. gr. 0.960-0.990.....gal.	.50		
Pinewood creosote, ref.....gal.	.48		

Naval Stores

The following prices are f.o.b. New York, for carload lots.

Rosin B-D, bbl.....280 lb.	\$17.00	—	\$18.50
Rosin E-1.....280 lb.	17.75	—	19.50
Rosin K-N.....280 lb.	20.50	—	23.00
Rosin W, G-W, W.....280 lb.	23.50	—	24.25
Wood rosin, bbl.....280 lb.	8.25	—	8.50
Spirit of turpentine.....gal.	1.68	—	1.69
Wood turpentine, steam dist.....gal.	1.65	—	1.65
Wood turpentine, dest. dist.....gal.	1.48	—	1.48
Pitch tar pitch, bbl.....500 lb.	13.50	—	14.25
Tar, kiln burned, bbl (500 lb.).....280 lb.	14.50	—	14.90
Retort tar, bbl.....280 lb.	14.50	—	14.90
Rosin oil, first run.....gal.	.86	—	.91
Rosin oil, second run.....gal.	.93	—	.98
Rosin oil, third run.....gal.	.95	—	1.07
Rosin oil, fourth run.....gal.	1.05	—	1.10

Solvents

73-76 deg., steel bbls. (85 lb.).....gal.	\$0.334		
70-72 deg., steel bbls. (85 lb.).....gal.	.314		
68-70 deg., steel bbls. (85 lb.).....gal.	.304		
V. M. and P. naphtha, steel bbls. (85 lb.).....gal.	.234		

Crude Rubber

Para-Upriver fine.....lb.	\$0.53	—	\$0.534
Upriver coarse.....lb.	.35	—	.354
Upriver caucho ball.....lb.	.34	—	.354
Plantation—First latex crepe.....lb.	.48	—	.48
Ribbed smoked sheets.....lb.	.33	—	.44
Brown crepe, thin, clean.....lb.	.33	—	.44
Amber crepe No. 1.....lb.	.48	—	.48

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls.....lb.	\$0.18	—	\$0.19
Castor oil, AA, in bbls.....lb.	.21	—	.22
China wood oil, in bbls.....lb.	.22	—	.23
Cocoonut oil, Ceylon grade, in bbls.....lb.	.17	—	.18
Cocoonut oil, Cochín grade, in bbls.....lb.	.19	—	.20
Corn oil, crude, in bbls.....lb.	.23	—	.23
Cottonseed oil, crude (f.o.b. N. Y.).....lb.	.18	—	.19
Cottonseed oil, summer yellow.....lb.	.24	—	.24
Cottonseed oil, winter yellow.....lb.	.25	—	.254
Linseed oil, raw, car lots.....gal.	1.65	—	1.65
Linseed oil, refined, car lots.....gal.	1.25	—	1.25
Linseed oil, boiled, car lots.....gal.	1.70	—	1.82
Linseed oil, commercial.....gal.	2.40	—	2.50
Palm, Lagos.....lb.	.16	—	.16
Palm, bright red.....lb.	.16	—	.17
Palm, Niger.....lb.	.16	—	.17
Peasut oil, crude, tank cars (f.o.b. mill).....lb.	.21	—	.24
Peasut oil, refined, in bbls.....lb.	.24	—	.24
Rapeseed oil, refined in bbls.....gal.	1.50	—	1.60
Rapeseed oil, blown, in bbls.....gal.	1.57	—	1.70
Soya bean oil (Manchurian), in bbls., N. Y.....lb.	.173	—	.173
Soya bean oil, tank cars, f.o.b., Pacific coast.....lb.	.143	—	.154

FISH

Winter pressed Menhaden.....gal.	\$1.28	—	\$1.31
Yellow bleached Menhaden.....gal.	1.30	—	1.31
White bleached Menhaden.....gal.	1.32	—	1.34
Blown Menhaden.....gal.	1.34	—	1.38

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated.....ton	\$25.00	—	\$36.00
Barytes, of color.....ton	20.00	—	25.00
Blanc fixe, dry.....ton	.034	—	.04
Blanc fixe, pulp.....ton	35.00	—	47.50
Casein.....lb.	.16	—	.18
Chalk, English, extra light.....lb.	.07	—	.07
Chalk, English, light.....lb.	.044	—	.06

Chalk, English, dense.....lb.	\$.04	—	\$.05
China clay (Kaolin), imported, lump.....ton	25.00	—	35.00
China clay (Kaolin), imported, powdered.....ton	30.00	—	60.00
China clay (Kaolin), domestic, lump.....ton	10.00	—	20.00
China clay (Kaolin), domestic, powdered.....ton	25.00	—	40.00
Feldspar.....ton	12.00	—	16.00
Fluorspar, acid grade, lump, f.o.b. mines.....net ton	30.00	—	35.00
Fluorspar, acid grade, ground, f.o.b. mines.....net ton	35.00	—	45.00
Fuller's earth, domestic, powdered.....ton	30.00	—	40.00
Fuller's earth, imported, powdered.....ton	30.00	—	40.00
Pumice stone, imported.....lb.	.03	—	.06
Pumice stone, domestic.....lb.	.024	—	.024

Talc, imported.....ton	55.00	—	60.00

Refractories

Following prices are f.o.b. works:

Chrome brick.....net ton	80-90 at Chester, Penn.
Chrome cement.....net ton	45-50 at Chester, Penn.
Clay brick, lat quality fireclay.....net ton	35-45 at Clearfield, Penn.
Clay brick, 2nd quality.....net ton	30-35 at Clearfield, Penn.
Magnesite, double burned.....net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2 in.....net ton	80-90 at Chester, Penn.
Silica brick.....net ton	41-45 at Mt. Union, Penn.

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....net ton	\$200.00	—	\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon.....lb.	.25	—	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon.....lb.	.70	—	.70
Ferro-manganese, 70-80% Mn.....gross ton	105.00	—	115.00
Spiegeleisen, 16-20% Mn.....gross ton	35.00	—	36.00
Ferro-molybdenum, per lb. of Mo.....gross ton	5.00	—	6.00
Ferro-silicon, 50% Si.....gross ton	85.00	—	95.00
Ferro-silicon, 75% Si.....gross ton	150.00	—	175.00
Ferro-silicon, 10-15% Si.....gross ton	45.00	—	60.00
Ferro-tungsten, 70-80% per lb. of contained W.....lb.	1.25	—	1.40
Ferro-uranium, 35-50% of U.....lb.	7.00	—	7.00
Ferro-vacuum, 30-40% per lb. of contained V.....lb.	5.50	—	7.00

Ores and Semi-finished Products

Chrome ore, 35-40% Cr ₂ O ₃unit	\$0.60	—	\$0.80
Chrome ore, 48% and over.....unit	1.90	—	1.00
Coke, furnace, f.o.b. ovens.....net ton	5.00	—	5.00
Coke, furnace, f.o.b. ovens.....net ton	4.00	—	5.50
Petroleum coke, refinery, Atlantic seaboard.....net ton	13.00	—	13.00
Fluorapatite, gravel, f.o.b. mines.....net ton	20.00	—	25.00
Manganese ore, chemical (MnO ₂).....gross ton	60.00	—	70.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂lb.	.75	—	.85
Tungsten, Scheelite, 60% WO ₃ , and over, per unit of WO ₃unit	9.00	—	15.00
Tungsten, Wolframite, 60% WO ₃ , and over, per unit of WO ₃unit	7.50	—	10.00
Uranium oxide, 96%.....lb.	6.00	—	6.00
Vanadium pentoxide, 99%.....unit	.13	—	.13
Pyrites, foreign, lump.....unit	.13	—	.13
Pyrites, foreign, fine.....unit	.13	—	.13
Pyrites, domestic, fine.....unit	.14	—	.174
Ilmenite, 52% TiO ₂ , f.o.b. N. Y.....net ton	40.00	—	40.00
Rutile, 95% TiO ₂ , f.o.b. N. Y.....net ton	200.00	—	200.00
Carnotite, minimum 2% U ₃ O ₈ , per lb. of U ₃ O ₈lb.	2.75	—	3.00
Zircon, washed, iron free, f.o.b. N. Y.....net ton	135.00	—	135.00
Monsieite, per unit of ThO ₂ , f.o.b. N. Y.....unit	42.00	—	42.00

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags.....bbl.	\$2.80		
Portl. lime, common, including contained.....300 bbl.	2.65		
Common brick, at dock.....M.	16.00		
Yellow pine, 3x4 to 8x8, 20 ft. and under.....M.	48.00		
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago.....M.	50.00		
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis.....M.	50.00		
Roofing, tar felt (14 lb. per 100 sq. ft.).....ton	60.00	—	70.00
Roofing, tar pitch (100 lb. bbl.) carlots.....ton	21.00		
Roofing, asphalt pitch carlots.....ton	24.00		
Roofing, asphalt felt carlots.....ton	63.00		
Roofing, slate-surfaced, per roll of 108 sq. ft. carlots.....ton	2.25		
Roofing, slate-finished shingles, 100 sq. ft. carlots.....ton	6.00		
Linseed oil, raw in barrels.....gal.	2.15		
Linseed oil, 5 gal. cans.....gal.	2.30		
Red lead, dry, 100 lb. keg.....lb.	.13		
Red lead, in oil, 100 lb. keg.....lb.	.14		
Red lead, dry, 5 lb. cans.....lb.	.14		
Red lead, in oil, 5 lb. cans.....lb.	.164		
White lead, dry and in oil, 100 lb. keg.....lb.	.13		
White lead, dry and in oil, 25 and 50 lb. kegs.....lb.	.13		
White lead, dry and in oil, 5 lb. cans.....lb.	.15		

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....100 lb.	\$2.45		
Angles, 3 to 6-in., 1-in. thick.....100 lb.	2.45		
Tees, 3-in. and larger.....100 lb.	2.45		
Plates.....100 lb.	2.66		
Rivets, structural, 3-in. and larger.....100 lb.	4.20		
Rivets, common for boilers, 3-in. and larger.....100 lb.	4.30		
Sheets, No. 28 black.....100 lb.	4.35		
Sheets, No. 10 blue annealed.....100 lb.	3.55		
Sheets, No. 28 galvanized.....100 lb.	5.70		

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Note—These items were compiled as of Nov. 12, but appear in this issue due to the delay in publication due to the printers' strike

Arizona

CANON—The Kay Copper Co. is in the market for a large compressor, drills, machine sharpeners, hoist and engines for sinking the new 3-compartment 1000-ft. shaft at the Kay mine here. Estimated cost, \$25,000. F. S. Poss, Adams Hotel, Phoenix, superintendent. Noted Sept. 14.

GLOBE—The Iron Cap Copper Co. had plans prepared for the construction of a coarse crushing plant at mine of No. 7½ gyratory and 48-in. Symons disc crushers. The company will be in the market for mill equipment of all sorts. Estimated cost, \$200,000. E. G. Morgan, superintendent. Noted Apr. 15.

KELVIN—The Gila Development Co. plans to construct a 25-ton mill 6 miles east of here, consisting of crusher, rolls and Chilean mill and plates; ore free milling, in upper part of mine. Will probably add Wilfley tables and possibly a cyanide plant early in the coming year. Tailings from initial operations to be stacked for future treatment by cyanide process, if desirable. The company will be in the market for tables, cyanide equipment, etc. Estimated cost, \$15,000. J. C. Devine, superintendent.

KELVIN—The White Metals Mining Co. plans to construct a complete concentration plant. The company will be in the market for breakers, rolls, tube or ball mill, classifiers, tables and a flotation unit of some sort. Estimated cost, \$30,000. J. C. Devine, manager.

California

WHITTIER—The Standard Oil Co., 1727 North Spring St., Los Angeles, has purchased a site of 93 acres near here and plans to construct an oil refinery on same.

Colorado

FT. COLLINS—The State Board of Agriculture will soon award the contract for the construction of a 3-story, 52 x 106-ft. physics building on the grounds of the Agricultural College. Estimated cost, \$100,000. Maurice Briscoe, 243 Boylston St., Boston, Mass., architect.

Connecticut

WATERBURY—The American Brass Co., Grand and Meadow Sts., has awarded the contract for the construction of a 1-story, 88 x 420-ft. factory addition on Freight St. to the Torrington Building Co., 197 Water St., Torrington. Estimated cost, \$125,000.

Florida

TALLAHASSEE—The city plans to build one mile of sewer and a septic tank on Duval and Bronough Sts. Estimated cost, \$10,000.

Idaho

BOISE—The Idaho Co-operative Sugar Co., 90 Idaho St., plans to erect 4 large beet sugar factories, southwest of here. Estimated cost, \$2,000,000. R. G. Cole, manager.

Illinois

CHICAGO—Adams & Elting Co., 716 West Washington St., has awarded the contract for the construction of a 1-story, 32 x 40-ft. and a 1-story, 26 x 48-ft. paint manufacturing plant at Kostner Ave. and Taylor St. to A. C. Thielberg, 154 West Randolph St. Estimated cost, \$100,000.

CHICAGO—The Ideal Coated Paper Co., 38 South Dearborn St., has awarded the contract for the construction of a 2-story, 79 x 135-ft. factory, at 4329 South Western Ave., to E. W. Sproul Co., 2001 West 39th St. Estimated cost, \$90,000.

CHICAGO—Sears Roebuck & Co., Howard and Homan Aves., has awarded the contract for the construction of a 5-story, 125 x 127-ft. addition to its wall paper factory, to the Dahl-Stedman Co., 11 South LaSalle St. Estimated cost, \$225,000. Noted Sept. 14.

EVANSTON—The International Lubricant Co., Ltd., 350 North Clark St., Chicago, will soon award the contract for the construction of a 2-story, 50 x 100-ft. factory on Greenleaf Ave. Estimated cost, \$20,000. D. H. Burnham & Co., 209 South LaSalle St., architect.

Kansas

NESS CITY—The Board of Education is having plans prepared for the construction of a 3-story high school. Plans include a septic tank and private water supply system. Estimated cost, \$65,000. R. A. Curtis, Kansas City, Mo., architect.

WICHITA—The Sterling Oil & Refining Co., 511 Beacon Bldg., plans to construct an oil refinery. Estimated cost, \$100,000.

Maryland

BALTIMORE—The Edro Richardson Brass Co., 318 North Holliday St., will soon receive bids for the construction of a brass foundry on Exeter St. Estimated cost between \$15,000 and \$20,000.

BALTIMORE—The Zem Chemical Co., Inc., 211 North Calvert St., recently organized, plans to construct a factory for the manufacture of patented chemical preparations. Address R. I. Esslinger, 1514 East Baltimore St.

Massachusetts

EAST BOSTON—L. Young & Co., 85 Borden St., will soon award the contract for the construction of a 2-story, 74 x 80-ft. factory on Borden St. Estimated cost, \$28,000.

Michigan

ANN HARBOR—The University of Michigan will soon award the contract for the installation of laboratory equipment in the proposed 6-story hospital which it plans to build on East Ann St. Estimated cost, \$1,000,000. Albert Kahn, Marquette Bldg., engineer and architect.

DETROIT—The Detroit Motor Castings Co., toine St., plans to build a 4-story hospital at Hamilton Boulevard and Blaine Avenue. A laboratory will be installed in same. Estimated cost, \$350,000.

DETROIT—The Detroit Motor Castings Co., Beaumont St., is having plans prepared for the construction of a 1-story, 60 x 155-ft. brass foundry. Estimated cost, \$35,000. Louis Sciscore, 225 Farwell Bldg., architect.

DETROIT—The National Oxygen Co., 176 Oakland Ave., has awarded the contract for the construction of a 1-story, 40 x 22-ft. oxygen factory to Hazleton & Clark, Hook Bldg. Estimated cost, \$10,000. Noted Sept. 14.

GRAND RAPIDS—The Kent Steel Co., 523 Bond Ave., has purchased a site on Scribner Ave., and plans to build a fabricating factory on same.

HAMTRAC—The Acme White Lead & Color Works, St. Aubin Ave., and Michigan Central R. R., has awarded the contract for the construction of a 4-story, 73 x 161-ft. paint factory, to the Foundation Co., Hotel Staffer, Detroit.

Missouri

ST. JOSEPH—The St. Joseph Structural Steel Co., 4th and Franklin Sts., plans to construct a steel plant at 8th and Atchison Sts. Estimated cost, \$75,000. Work will be done by day labor.

Nebraska

BATTLE CREEK—The city is making surveys for the construction of a sewerage system and a disposal plant. Estimated cost, \$45,000. W. E. Standeven, 617 Bee Bldg., Omaha, engineer.

New Jersey

EDGEWATER—The U. S. Aluminum Co. has awarded the contract for the construction of an 80 x 450-ft. and an 80 x 176-ft. steel factory, to the Turner Construction Co., 244 Madison Ave., New York City. Estimated cost, \$1,000,000.

PHILADELPHIA—The city has awarded the contract for constructing and equipping the proposed waste disposal plant, to the Municipal Disposal Co., Philadelphia, \$137,980. Noted Feb. 15.

New York

BELMONT—The Horden Condensed Milk Co., 108 Hudson St., New York City, has awarded the contract for the construction of a 2-story, 140 x 270-ft. powdered milk plant, to the Jamestown Construction Co., 60 River St., Jamestown.

GENEVA—The Geneva Glass Manufacturing Co., Avenue P and Ontario St., recently organized, will construct an addition to the plant of the old Geneva Glass Co., and install new machinery in same. Estimated cost between \$50,000 and \$60,000. Address J. O. Jensen, Ontario St.

NAGARA FALLS—The National Carbon Co., Madison St., N. W. and West 17th St., has awarded the contract for the construction of a 1-story, 60 x 100-ft. coke drier plant to P. McKinney Corporation, Gluck Bldg. Estimated cost, \$40,000.

SYRACUSE—The Onondaga Milk Producer Co-operative Association has awarded the contract for the construction of a dairy on Burnet Ave., to W. J. Burns, Keith Bldg. A bacteriological laboratory will be installed in same. Estimated cost, \$100,000.

North Carolina

SPRINGHOP—The city will soon award the contract for the construction of a sewage disposal plant. Estimated cost, \$60,000. J. J. Wells, Rocky Mount, engineer.

Ohio

CLEVELAND—The Ohio Varnish Co., East 87th St. and Kinsman Rd., has awarded the contract for the construction of a 3-story, 56 x 97-ft. factory addition, to C. A. Rutherford Co., 1922 East 18th St. Estimated cost, \$40,000.

CLEVELAND—The Crescent Brass Manufacturing Co., 841 Lake Ave., has awarded the contract for the construction of a 4-and-a-half x 100-ft. factory, to the Webber Co., 1609 West 25th St. Estimated cost, \$50,000.

CLEVELAND—The Osborn Engineering Co., engineer, 2848 Prospect Ave., is receiving bids about Dec. 15 for the construction of a 3-story 100 x 150 ft. factory on Euclid Ave. and London Rd. for the Cleveland Fruit Juice Co., 1382 West 9th St. Estimated cost, \$150,000. H. A. Van Gorder, president. Noted Aug. 15.

CLEVELAND—The Osborn Engineering Co., engineer, 2848 Prospect Ave., is receiving bids for the construction of a 4-story, 51 x 110-ft. factory at 11700 Madison Ave., for the Glidden Varnish Co., Madison Ave. Estimated cost, \$110,000.

CLEVELAND—The Union Tire & Rubber Co., Hippodrome Bldg., is having plans prepared for the construction of a 1-story, 165 x 190-ft. rubber plant. Estimated cost, \$125,000. Osborn Engineering Co., 2848 Prospect Ave., engineer.

COLUMBUS—The American Zinc, Lead & Smelting Co., Pierce Bldg., St. Louis Mo., has purchased a tract on Windsor Ave. and plans to erect a plant for the manufacture of zinc oxide.

COLUMBUS—The Columbus Brass Co., 767 North 4th St., has awarded the contract for the construction of a 25 x 87-ft. factory, to C. W. Schneider & Son, Ohio Electric Terminal Bldg. Estimated cost, \$6000.

DAYTON—The Greene Engineering Co., Delphos, Ohio, plans to construct a 1-story, 60 x 135-ft. factory for the manufacture of aluminum pistons. Estimated cost, \$20,000. Treitzinger & Musselman, Union Bank Bldg., architects.

ELVRIA—The city has retained M. Knowles, engineer, Jones Law Bldg., Pittsburgh, Pa., to make a study and submit sketches for a filtration plant in connection with the proposed water supply.

MEDINA—The village plans to construct a sewerage system and a disposal plant. George Gascoigne, City Hall, Cleveland, engineer.

SPRINGFIELD—The Victor Rubber Co. has awarded the contract for the construction of a 1-story, 50 x 200-ft. and a 1-story, 48 x 100-ft. rubber factory on West St. to H. C. Largent, Springfield. Estimated cost, \$20,000.

VERMILION—The city has awarded the contract for the construction of a sewage disposal plant, to the American Construction Co., Marion Bldg., Cleveland. Estimated cost, \$25,000.

Oklahoma

BARTLESVILLE—The Washington County Medical Society plans to build a bacteriological laboratory. Estimated cost, \$35,000. Address Dr. A. North.

Pennsylvania

FRANKLIN—Morris Knowles, consulting engineer, Jones Law Bldg., Pittsburgh, is making a study and will submit report on a complete sewage disposal plant. Estimated cost, \$50,000. Noted June 1.

Texas

FORT WORTH—The Royal Duke Refining Co., P. O. Box 1400, has purchased a site along the Frisco R. R. and plans to construct a 1 and 2 story, 5000-bbl. oil refinery on same. E. E. Costley, Royal Duke Refining Co., engineer.

VAN ALSTYNE—The city has awarded the contract for the construction of a sewerage system, to include a disposal plant, to the James Contracting Co., Ranger. Estimated cost, \$32,000.

Washington

OROVILLE—The Pyganite Mining Co. plans to construct a 50-ton mill to treat silver ore. Tables and flotation machinery will be needed. Estimated cost, \$40,000. Monroe Harmon, manager.

West Virginia

FAIRMONT—The West Virginia Metal Products Co. has awarded the contract for the construction of a brass plant, consisting of an 80x280-ft. casting shop, 280x380-ft. machine shop and 150 dwellings, to F. T. Ley Co., 495 Main St., Springfield, Mass. Estimated cost, \$1,500,000. Noted June 16.

Wisconsin

CUMBERLAND—The city plans to excavate and lay a vitrified pipe sewer, also install a sewage disposal system, on Main St.; system not yet decided, probably gravity flow. Estimated cost, between \$25,000 and \$30,000.

KOHLER—The Kohler Co., care of W. J. Kohler, has awarded the contract for the construction of a 4-story, 60x250-ft. enamel ware factory, on Main St., to Worden-Allen Co., 208 South La Salle St., Chicago, Ill. Estimated cost, \$50,000.

MILWAUKEE—The Chain Belt Co., 736 Park St., has awarded the contract for the construction of a 1-story, 150 x 316-ft. malleable iron foundry, on 37th Ave. and Orchard St., to S. M. Siesel, 36 Michigan St. Estimated cost, \$200,000.

MILWAUKEE—F. Martin-Laskin Co., Fraternity and Keefe Aves., has awarded the contract for the construction of a 2-story, 60 x 140-ft. addition to its tannery to W. F. Tubising Co., Wauwatosa. Estimated cost, \$35,000.

PACKWAUKEE—The Cramer Memorial Institute, 204 Grand Ave., Milwaukee, will soon receive bids for the construction of a 3-story, 40 x 120-ft. sanitarium. A private water system and a septic tank will be installed in same. Estimated cost, \$100,000. Backes & Pfaffler, M. & M Bank Bldg., Milwaukee, architect and engineer.

SHEBOYGAN—The Badger State Tanning Co., South Water St. and Maryland capare, plans to build a 3-story, 60 x 250-ft. tannery on Water St. Estimated cost, \$50,000. Architect not selected.

WAUWATOSA—The City Council plans to build a sewage disposal plant. Estimated cost, \$30,000. J. E. Lowther, city engineer.

Ontario

BROCKVILLE—The Brockville Paper Manufacturing Co. will soon receive bids for the construction of a factory on Park St. Estimated cost, \$60,000.

PETERBOROUGH—The city is having plans prepared for the installation of slow sand filters on the old Carnegie property, capable of about 4,000,000 gal. per day. Estimated cost, \$200,000. W. Parsons, City Hall, engineer. Noted Feb. 1.

Coming Meetings and Events

THE AMERICAN IRON AND STEEL INSTITUTE will hold its sixteenth general meeting at the Hotel Commodore, New York, Oct. 24 and 25.

THE SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall convention Oct. 29 to 31 inclusive, at Cleveland, Ohio.

THE SOUTHERN FERTILIZER ASSOCIATION will hold its annual meeting Wednesday, Nov. 5, 1919, at 10 A. M. at Piedmont Hotel, Atlanta, Ga.

FOURTH INDUSTRIAL SAFETY CONGRESS of New York City will be held at the Hotel Onondaga, Syracuse, N. Y., Dec. 1, 2, 3 and 4, 1919.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual meeting Dec. 3 to 6 at Savannah, Ga.

Industrial Notes

THE JEFFREY MFG. CO., of Columbus, Ohio, has taken out group life insurance with the Travelers, effective Oct. 25, covering its 2200 employees. The increment of the insurance is \$100 a year up to and including the fourth year, when an amount of \$800 is attained. For the fifth year the amount jumps to \$2000 and then increases \$200 a year to \$4000. The whole plan is retroactive.

MR. F. C. WORTH, consulting engineer, 309 Monadnock Block Bldg., Chicago, is preparing plans and specifications for two plants in the United States located at the mines, for grinding fuller's earth. It is reported that the projects will be fully equal to that which is now being imported from England for bleaching and refining lard, table and mineral oils, and sugar. The National Association of Purchasing Agents, in considering arrangements of catalogs, and particularly the confusion regarding the location of the index, has officially recommended that the placing of the index at the back of the book should be made a standard practice. The Association's standardization committee has recommended a tentative standard form for invoices, check and vouchers.

THE CHESAPEAKE IRON WORKS, of Baltimore, Md., manufacturer of the Chesapeake electric traveling cranes, has recently announced the opening of its New York office in the Woolworth Bldg. The office will be in charge of Mr. H. L. Mode.

THE AMERICAN CHAMBER OF COMMERCE FOR BRAZIL announces the appointment of Mr. Leslie Freeman as resident representative of the Chamber in the United States. Mr. Freeman's office will be at 37 Liberty St., New York City. He extends the benefits of the organization to American manufacturers, exporters and importers in Brazil.

THE EAST IRON & MACHINE CO., Lima, Ohio, has purchased the Van Wie Pump Co., of Syracuse, N. Y., and is now manufacturing a new centrifugal pump. The East Iron & Machine Co., at its plant in Lima, will at once begin to manufacture vertical and horizontal centrifugal pumps of double suction, single suction, and centrifugal pumps, single acting triplex pumps and vertical steam engines, and will also make parts for all Van Wie products.

THE PATENTORS' PATENTERS CO., a corporation whose organization was interrupted in 1917 by the war, has resumed work at 325 W. Madison St., Chicago. The officers and directors of the company are: G. M. Salmon, C. H. Beam, W. H. Harrison, C. G. Rasbach, J. R. Cole, B. D. Burns. This organization is owner of formulae and processes for the manufacture of substitutes and artificial leather, and is also engaged in paper and paper. The company also expects to manufacture a full line of all grades and finishes, thereby covering the entire field of material for the construction of paper. There is an authorized capitalization of \$3,000,000 divided into 300,000 shares of \$10 par value.

The company claims that the processes and formulae produce an article, which is superior to any other on the market. This is accomplished by the direct application of the film to the fabric base. The company also claims to eliminate the appearance of the web of the fabric base on the filmed side of the finished product, while the most important claim is the retention of thorough pliability under regular ordinary wearing conditions. The film is said to have properties of great tensile strength and toughness. Plans are under way to locate the plant in Louisville, Ky. It is expected that the complete erection of the factory for producing this material will be accomplished in about four months' time.

THE BRITISH AMERICAN CHEMICAL CORPORATION announces the removal of its office from Ridgefield Park, N. J., to 109-111 Beekman St., New York City.

THE SUGAR LAND MFG. CO., Sugar Land, Texas, is enlarging its sulphuric acid plant from 50 tons daily capacity to 100 tons. It has three new concentrators in operation and one under construction, and also two new towers. The construction work was planned and is under the direct supervision of Mr. L. D. Lansdale, superintendent of the acid plant.

THE DENVER BOULDER & WESTERN RAILROADS has been purchased by the Morse Bros. Machinery & Supply Co. of Denver. This road, 49 miles in length, located in Boulder County, connects Ward and Eldora with Boulder and the main line of the Denver & North Western R.R. It is a narrow gauge line, laid with 56-lb. rail, and is equipped with 8 locomotives, 90 freight cars, and passenger coaches.

The Morse Bros. company has offered this road to the mining men and commercial organizations of Boulder County at a price considerably below its scrap value in order that the road may remain and be of service to the community. An earnest effort is being made by these organizations to save the road from being taken up. The cost of the road was considerably over \$1,000,000. Permission has been given the owners by the Public Utilities Commission of Colorado to dismantle the road, which will be done at once in case the Boulder organizations and men are not

sufficiently interested to save it. The Morse Bros. Machinery & Supply Co. also announces that the Argentine & Grays Peak Railroad is being dismantled. This road starts from Silver Plume, Colo., and goes to the summit of Mt. McClellan, 14,000 ft. elevation above sea level. It was used for 17 miles as a tourist road and is now being served at a valuable rate. It was equipped with 40-lb. steel and gasoline cars and Shay locomotives. All of the material is being brought to Denver for resale.

THE QUIGLEY FURNACE SPECIALTIES CO., New York City, announces that at the sheet mill of the Mansfield Sheet & Tin Plate Co., Mansfield, Ohio, extensions are being made, comprising six new sheet mills, four new furnaces, and a new gas engine. The entire furnace installation in this extension will be powdered coal fired. For this work the Quigley air transport system for distributing powdered coal together with Quigley powdered coal feed controllers, burners, etc., will be installed.

THE MASSACHUSETTS OIL REFINING CO., INC., of East Braintree, Mass., is erecting a refinery, which when completed will cost about \$2,500,000. The refinery is designed to have a capacity of 5,000 bbl. per day, and will run crude oil, which has been purchased from the Island Oil & Transporting Corp., under contract, and from this crude oil will be extracted gasoline, kerosene, lubricating oils, and wax. The usual steel storage tanks and stills, with warehouse, garage and office buildings, are being erected. The design engineers and contractors for the work are Richmond Levering & Co., Inc., New York City.

MR. J. V. N. DORR of the Dorr Company, New York City, purchased about two years ago, a picturesque stretch of woodland and an old mill at Westport, Conn. The scope of the work at Westport includes analyses, chemical and biological investigations, and the development, testing and improvement of industrial, chemical and metallurgical processes. The mill has been entirely remodeled and refitted with an attractive, modern building. The new sleeping accommodations for transient business visitors, a completely equipped analytical laboratory, and a testing plant of commercial scale, including many pieces of scientific machinery, both up and down the two rivers, the Saugatuck and the Aspetuck, is a tract of land consisting of 46 acres, some in meadows and hillsides, some in wood and some in the heart of the natural woodland. Through the untiring efforts of Mr. Herbert Fox and the generosity of Mr. Dorr, and their co-operation with the Nature Club of Westport, the services of Mr. J. V. N. Dorr, state game warden, were obtained and through him the property was leased by the State for a bird and game reserve and is now protected by the law from any kind of trespass, trapping, and is under the jurisdiction of Mr. Smith and under the care of the Nature Club. Mr. Dorr has asked the Nature Club to establish feeding places to attract the birds. These have all been occupied this past summer, demonstrating clearly that the birds readily accept the offerings of their human friends.

Manufacturers' Catalogs

THE AUSTIN COMPANY, Cleveland, Ohio, calls attention to Catalog No. 9, which briefly outlines its scope of construction and equipment service. It contains cross-sections of the ten Austin standard types of buildings and a description of service to foundry and steel plant owners.

THE UNITED METAL HOSE CO., INC., New York City, has issued Folder 100, and a leaflet, on flexible metal hose for the oil industry.

THE CARRIER ENGINEERING CORP., Inc., New York City, has just received from the press an attractive catalog entitled "Weather and the Story of How It Is Made." This 22-page catalogue catalog illustrates and describes in an interesting manner its service to many manufacturing establishments in the manufacture of weather—burning, location, dehumidification, heating, cooling, refrigeration, ventilation, control of moisture regain, and drying.

THE BAUSCH & LOMB OPTICAL CO., Rochester, N. Y., announces a new illustrated manual and catalog of optical glass which contains treatises on the theory and history of optical glass manufacture, including the story of its pioneer work along the line of American practice, and during the war. This company also has issued recently a comprehensive, well-illustrated catalog on microscopes, which marks the restoration of this line to its normal status, together with several new models and features.

THE CELITE PRODUCTS CO., New York City, has issued a new and interesting bulletin describing in detail the requirements and practice of insulating various types of furnaces, such as annealing, heating, forging, malleable, gun, glass, etc. Copies of this bulletin, B-S-A, will be mailed upon request.

THE WALTER A. ZELNICKER SUPPLY CO., St. Louis, has issued Bull. No. 270, entitled "The Nation's Market Place." This bulletin covers rails, locomotives, engine machinery for power and industrial plants, contractors' equipment and every kind of pipe, steel piling and tanks. Attention is also called to Bull. No. 266, entitled "Rails." Copies will be sent upon request.

Number 11

An Announcement To Our Readers

ADVERSITY has its uses, which, of course, has been known since time began, if only to marshal one's friends. Our own recent engagement with the radicals, then, served to do one very fine thing, and that was to draw spontaneously from many of our readers sincere expressions of sympathy and words of cheerful encouragement in the fight in which we felt, not egotistically, that we were engaging in more than a personal struggle in a sharp engagement where it was necessary for the general welfare to demonstrate that as we intend to perform our contractual agreements with unionism, so must unionism fulfill its counter obligations.

Happily, the issue has been decided in favor of responsible unionism, but only after an immense loss in wages, income and convenience, and luckily in a manner which apparently will leave not even temporary rancor except in the case of a few irreconcilables.

The pressing problem now before us is to "catch up." CHEMICAL & METALLURGICAL ENGINEERING is the first of the McGraw-Hill papers to be returned to our own plant in New York, so that with our specially developed facilities it will easily be possible from a mechanical standpoint to be even with the date line by New Year's. Ten issues, however, will need to be mailed during the space of time ordinarily covered by five!

Two courses are open. One is to catch up as fast as possible with the delayed issues, bringing out an issue, say, every four days until we are again even with the calendar. The other alternative is to double up the editorial section for two issues, thus bringing the reader up to date.

This latter alternative, it is hardly necessary to say, is vastly more expensive, inasmuch as we, by so doing, will omit the equivalent of five complete issues of advertising. We feel, however, that it is a matter of duty on our part to bring the reader up to date with his issues just as soon as possible, and also a duty on our part to pay the cost of this strike out of our own pockets and not pass it along to the advertiser. It is the McGraw-Hill Company's cash contribution toward sane American industrialism..

In this issue, therefore, we are publishing a double section of reading matter, with the advertising section that corresponds to one issue only. It is also important to take the line at the head of this page literally; that is, the news features in this issue were compiled but a few days previous to press date. To put this idea actually in effect, all back price lists are gathered in a supplement herewith, so that we can start with a clean slate.

A Suggestive Theory on Sonims

OVER a year ago COSMO JOHNS proposed an idea regarding the genesis of oxidized compounds in steel which has apparently not been given the amount of attention it deserves as a consistent explanation of the rather meager data at hand and a basis for further research. He starts with the assumption that iron oxide has a finite solubility in liquid steel, but is virtually insoluble in the solid—in other words, the system is analogous to the well-known Cu:CuO equilibrium, where a eutectic of metal and oxide exists at the crystal boundaries. Thus in a bath of steel at its melting point there is a certain equilibrium existing in the system Fe:C:Mn:Si:FeO, which is disturbed both as to temperature and concentration as the solidification range is passed, iron oxide concentrating at the borders of the austenite crystals. But now this concentrated oxide reacts with the dissolved manganese and silicon, forming mixed silicates of iron and manganese *in situ*, thus producing solid non-metallic inclusions whose composition varies, among other factors, as the relative concentrations of silicon and manganese metal, and their affinity for oxygen.

But carbon is also present, and it is oxidized by the iron oxide as well. Thus gaseous compounds form, carbon monoxide always predominating because of equilibrium conditions at the high temperature. However, the dioxide is always present—and found, corresponding fairly closely to the volume relationship between the two oxides theoretically required by the C:CO:CO₂ equilibrium. However, methods of determining gas in steel are so far from precise that only general relationships can be inferred from currently published analyses.

The theory accords well with the general impression that low-manganese or silicon steels favor a gaseous end product and consequent blowholes, a result of gas formation in pasty material. High-manganese or silicon steels favor a larger total of solid oxidized materials; gases also form, however, and usually are found to an extent roughly proportional to the amount of sonims. An increased volume in gas is formed at a lower temperature and is retained either in solution or at high pressure at crystalline boundaries in sub-microscopic cavities.

One needs only to call to mind the troublesome "flakes" to remember how effectually a small amount of iron oxide or "oxidized impurity" deteriorates the quality of really excellent steel. Obviously, any well-reasoned contribution along the lines indicated above is a step toward the ultimate explanation of most perplexing and disconcerting heterogeneities appearing now and then in ferrous alloys.

A Scientific Union

From Chicago's City Hall

SCIENTIFIC Laboratory Union No. 16986, chartered by the American Federation of Labor, comes forth with the publication of an open letter exhorting laboratory workers everywhere to secure the benefits of organization such as "the encouragement of higher degree of skill and efficiency," a reduction in hours of labor, the adoption of a minimum wage scale, and so on. The letter consigns "the false monarch" Ethics to a niche in the Hall of Fame, where in some unexplained manner "it will serve to give us a living wage consistent with the trend of modern times."

In poor English and worse logic it proceeds along the time-honored lines of labor propaganda, advancing as a clincher that "Specialists have agreed that living costs have advanced 72 per cent since 1913." Ordinarily, in comparing the trend of prices, one turns to the well-known index numbers. When expressed as percentages of the index number for 1913 these figures are quoted as follows for June, 1919, the last month available: Bureau of Labor Statistics, 326 commodities, 207; Annalist, 25 commodities, 216; Bradstreet, 96 commodities, 196; Dun, 200 commodities, 189; Gibson, 22 commodities, 212. Unfortunately the agreeing authorities—those specialists notoriously hard to bring into exact agreement—are not designated by the Scientific Laboratory Union's publicity agent; but without contending that wholesale price index numbers are representative of living cost to laboratory assistants on our part it is at least apparent how easy it is to befuddle judgment by quoting "authoritative figures" and that the agreeing specialists have overlooked a bet in their figure on the high cost of living.

Ethics, or the science of conduct in the shaping of organized existence, will hardly be recognized if we cannot expect more mature thought in the minds of scientific and educated men than has been evidenced in this case.

Industrial Conference Splits On Collective Bargaining

AS INTIMATED in these columns, and as frequently expressed at the Industrial Conference in Washington, the steel strike resolution and the one on collective bargaining proved too much for the weak cohesion of that body, and it went to pieces after both measures had been defeated. Labor stood alone in its support of the resolution to adjudicate the steel strike, being opposed by the groups representing the Public and the Employers. And on the subject of collective bargaining, each of the groups cast the sole affirmative vote on its particular form of resolution, being opposed in each case by the two other groups. An impasse being thus reached, Labor withdrew from the Conference, being led out by Mr. GOMPERS in spite of an earlier appeal from the President urging that "a happy conclusion" be reached.

It is worth while to examine a little more closely the disagreement on collective bargaining, because in the abstract that is a subject on which all the elements of the Conference were in agreement. It was in the concrete application of the principle, the machinery, the *modus operandi*, that the different groups of the Conference failed to agree. In brief, the crux of the matter was whether the unions should be the repre-

sentatives of the workers in industrial arbitration; whether employers should be required to confer with union agents only as representatives of their employees.

The resolution presented by Mr. Gompers read as follows:

"The right of wage-earners to organize in trade and labor unions, to bargain collectively, to be represented by representatives of their own choosing in negotiations and adjustments with employers in respect to wages, hours of labor, and relations and conditions of employment, is recognized."

Controversy waged about the interpretation of the phrases "in trade and labor unions," and "representatives of their own choosing," because it was urged that these would practically imply enforced recognition of the unions and enforced dealing with union agents. Compromise was sought in various amendments more broadly expressed. No one questioned the right of the workers to organize, but the Employers suggested that "shop industrial councils and other form of lawful associations" as well as "trade and labor unions" be recognized as suitable representatives of employees in collective bargaining. The Public Group suggested "associations of their own choosing" as proper mediums through which employees might negotiate with employers. But to these and other proposals Labor was adamant. Apparently nothing would be acceptable but the wording proposed by that group! It was as fine an effort to promote unionism and fasten its tenets on American industry as has ever been witnessed; and had it been successful it would have committed American industry to a narrow line of development in industrial democracy.

No sane man can oppose the principle of collective bargaining on the part of either employers or employees, or both. It involves the same principles of barter and sale that apply in everyday commercial transactions. In the old Yankee parlance it involves "swapping" one thing for another. If a "swap" is proposed, each party considers what it may gain or lose, and finally decides either to trade or not. No compulsion rests on either side, and neither has the right to force the other to trade if he doesn't want to. But—if a trade is agreed upon, the moral obligation rests upon both parties to abide by the terms of the deal and carry out the agreement. And right there is where Labor has fallen in the public esteem, for of late its contracts and agreements have been scraps of paper. That this condition is not approved by conservative labor leaders does not lessen Labor's responsibility. Rather it weakens faith in the ability of those leaders to check the effects of radical teachings, and points to the necessity of other measures if we are to escape the consequences of irresponsible leadership. In our judgment Labor was too obstinate in holding for its own language in the resolution. It refused to accept amendments or interpretations that would recognize other forms of employees' associations than trade and labor unions, and thereby lost the support of even the friendly Public Group in the Conference.

Labor came out of the Conference with less prestige than it entered. It was too combative. We recognize clearly the reasons for the fighting attitude of Labor in years past, when it was endeavoring to establish the justice and right of a day's wage and the right of association in unions. But that time

has passed. The attitude of employers in general is progressive, and the temper of the time calls for friendly conciliation and arbitration. Fundamentals of industry are more clearly appreciated now than before, and men who are willing to think can get together.

If the war taught one lesson supremely, it was that force does not get far in this generation—at least not much farther than the Marne! And if we were to suggest an idea to Labor it would be to do more thinking and less fighting.

Restoration of Foreign Exchange

IT IS a curious thing that after the Armistice the breakdown in foreign exchange was not generally foreseen. The United States was exporting a great deal more than it was importing, and borrowing by foreign countries could not continue indefinitely. Undoubtedly the bankers foresaw conditions that have since come to prevail, but certainly business men generally did not foresee. They were preaching that the opportunity must be quickly embraced for the United States to cultivate a large export trade or the opportunity would be lost. A year after the Armistice the Italian buyer has to pay more than double price for American goods, by reason of the exchange rate being so heavily against Italy.

It is not to the advantage of the United States that such conditions should exist. The extra price paid by the foreign buyer benefits no one. The whole system of exchange is a highly complicated one, and any merchandise movement that serves to increase the departure from normal in the exchange rate between two countries sends a disturbance through the whole system. It is very probable that if any expert on exchange had been asked how far exchange rates could depart from parity without breaking down the system he would have indicated limits far inside those that have been transgressed in the case of many of the rates lately current. There is, however, a breaking point. In domestic commerce a business house may suffer some impairment of credit whereby it pays a slight premium for goods it buys, or borrows money at a disadvantage, but the case does not go far until the house loses its credit altogether.

Perhaps business men were misled by the ease with which Great Britain held sterling exchange during the war. The process was simplicity itself. The rate was established and representatives of the British Government bought and sold exchange at the set rate, the British Government then borrowing from the United States from time to time such sums of money as were needed to fill the engagements. That was when Britain was at war. The process could not be continued, any more than war with its increasing dislocations could be continued forever.

Loans by the United States are named as a means of correcting the exchange situation, but the essence of such transactions must be understood. They would be medicine, not food. They would not support the countries to which they were made, but would be useful only by way of their enabling the countries to get into shape to support themselves. Bankers would make them if thereby it were certain the countries would be set on their feet.

The desideratum is that international trade be re-

stored to a normal and natural basis, whereby each country will import only what it can afford to import. The countries that have debts to outsiders cannot import much. They must export more than they import, or pay the balance in some other way. The United States was before the war a debtor nation and on account of this and other circumstances had to export more than it imported. Now the United States is a creditor nation, and also has a merchant marine, collecting freights from foreigners. It should import more than it exports or by its growing richer it would be in danger of bankrupting somebody.

The development of an import trade for the United States, however, presents a very difficult problem. The difficulty is apparent to anyone, but the difficulty is emphasized if one attempts to map out a program. One's first recourse would be to study in detail the import trade we had before the war, as that trade might represent a basis on which to build. This trade, however, presents a bewildering complication of details. For illustration, there is given below a list of the largest items of imports in the year before the war, the fiscal year ended June 30, 1914. The total imports amounted to \$1,893,925,657.

IMPORTS, YEAR ENDED JUNE 30, 1913

Hides and skins	\$120,289,781
Coffee	110,725,392
Sugar	101,649,375
Raw silk	100,930,025
Fiber manufactures	82,404,239
Unmanufactured rubber	76,162,220
Lumber	62,433,039
Fruit and nuts	53,421,258
Unmanufactured wool	53,190,767
New copper	39,551,268
Tin	39,422,479
Meat and dairy products	38,760,989
Alb. stuffs	36,540,551
Silk manufactures	35,454,786
Tobacco	35,029,055
Art works	35,010,449
Wool manufactures	34,294,204
Laces	33,865,822
Sisal grass	25,860,729
Animals	24,712,111
Crude cotton	20,797,790
Spirits, wines and malt liquors	20,347,546
Unmanufactured cotton	19,456,588
Nitrate of soda	17,950,786

One may well be dismayed by scrutiny of this list, so far as concerns its containing commodities that we may import in larger quantities so as to help the international trade situation.

In the case of most of the items we are glad to import all we can get, and in the case of many of the items it would be impossible for the outside world to increase its production.

The list, however, is illuminating in its way. For instance, it shows something that the average man would not have assumed, that we imported a greater value of crude cocoa, not yet ready to drink, than of spirits, wines and malt liquors, all ready. France has felt bad about our recently acquired dryness, but we imported two-thirds more laces than of all intoxicating beverages. France should make laces. Indeed, this little illustration furnishes the key to the whole matter.

The time was when economic policy dictated that we should import raw materials and keep our factories and workmen busy with them. Now the case is reversed and we need to import the highly manufactured goods that we have not labor supply enough to produce. We have the money with which to buy and there are many idle workmen in Europe. They need organization and incentive. Instead of sending salesmen abroad, as was urged just after the Armistice, we should send factory managers and organizers.

Readers' Views and Comments

Chemical Nomenclature and Spelling

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—I have read with much interest the article on Beryllium, entitled "Glucinum," by J. S. Negru, in the Sept. 15 number of your journal, page 353.

Reading this article makes me wonder if it would not be possible for the chemical journals of America to get together and all use the same form of chemical spelling and nomenclature, possibly that already adopted and made official by the American Chemical Society. In this same article you spell the word "sulfur" and its derivatives with "ph"; of course, this is still quite common in this country. So far as a choice between beryllium and glucinum or glaucinum is concerned, the matter, after being extensively discussed in *Science* (Dec. 9, 1904, Jan. 6, 1905, and Feb. 17, 1905), was brought up before the Council of the American Chemical Society and after an extended discussion there the Council voted almost unanimously—only one vote being in the negative—that "beryllium" was the proper term and that the Society should use it in all its publications, which it has always done since. In the first article published by Vauquelin he did not use the word "glucinum" at all, but spoke of a "la terre du Béril," which was naturally translated into German as "Berylerde" and when the material was separated later by Vauquelin when the word "beryllium" was first used, the French "glucine" was proposed by editors of the journal which published Vauquelin's article and the words "glucinum" and "beryllium" were used interchangeably in England. As the element is a metal, there can be no excuse for the word glucinum on any account, even if the root of the term now used in France is preferred. All metals should end in "ium."

But as I have said before, this has all been threshed out in arguments in *Science* as noted above. The main point that I wish to bring out is that for years now the American Chemical Society has maintained a Committee on Chemical Nomenclature and Spelling, a committee which has done hard work and which for several years co-operated with a committee of the American Association for the Advancement of Science to finally determine the procedure for the whole American Chemical Society. The Committee, after careful investigation and study, has adopted a certain form of spelling which is used in the journals of our Society. This is the only organized work done on spelling and nomenclature and should, I think, be adopted by all our chemical journals until such time as it is officially altered. Why, for example, our journals should continue the incorrect use of "ph" in sulfur simply because some bad speller put it in the English language is beyond my conception. The word comes from a Latin word which was originally spelled with an "f." Every other language in the world uses the "f" and not the "ph." Sulfur is spelled with an "f" in all chemical literature except some of that printed in the English language and for years has been so used in the journals of the American Chemical Society and also is authorized spelling in Webster's latest International Dictionary. It has been adopted by the Standard and Century Dictionaries and has been used solely by the Patent Office for some ten years back. We have too many badly

spelled words in the English language outside of chemical literature—words which have simply come into common use because certain of our early literary lights like Pope and Johnson were bad spellers. They are the abomination and stumbling block of all foreigners attempting to learn our otherwise simple language. Can't we all get together and try at least to have some common practice in the literature of chemistry?

CHARLES L. PARSONS.

Washington, D. C.

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—In the letter of Dr. Parsons, published above, the suggestions to use "sulfur" instead of "sulphur," and to have all the metals end in "ium" deserve no doubt all due attention, and it might be expected that we will also have soon "fosforus," "bismuthium" or "bismuthium," and so forth, instead of "phosphorus," "bismuth" and so forth.

As to using beryllium and not glucinum or glaucinum, I might refer to my letter published in *CHEMICAL & METALLURGICAL ENGINEERING*, Oct. 1, 1919, pp. 417-418, in which I have already mentioned the references quoted in Dr. Parsons' letter, which is dated Oct. 28, and also gave as references authorities using "glucinum" as late as September, 1919. It might help some to go back awhile and mention the following:

Roger Jones and Andrew Palmer obtained an English patent Feb. 23, 1623, for a process of "Making of hard soape with a material called berilia and . . . The 'berilia' consists of the ashes of beanstrawe, peasestrawe, and of English kelpe."

Humphry Davy stated, in a paper read before the Royal Society, June 30, 1808 (*Philosophical Transactions of the Royal Society of London*, Pt. II, p. 353), when speaking about the "Enquiries relative to the decomposition of alumine, silex, zircon and glucine": "Had I been so fortunate as to have obtained more certain evidences on this subject, and to have procured the metallic substances I was in search of, I should have proposed for them the names of alumium, silicium, zirconium and glucium."

John Dalton in his "A New System of Chemical Philosophy," Manchester, 1810, uses "glucine."

William Henry in his "Elements of Experimental Chemistry," Philadelphia, 1819, states on p. 220, Vol. I: "We have no knowledge of the base of glucine. When obtained its proper demonination will be *glucinum*. The general fact of its existence is proved by igniting glucine with potassium which is thus changed into potash."

Jacob Green in his "Textbook of Chemical Philosophy," Philadelphia, 1829, states on pp. 341-342: "Glucinum was first satisfactorily ascertained by Dr. F. Wöhler, near the close of the year 1823; till then glucina, a substance first discovered by Vauquelin in the beryl and emerald, was only supposed from analogy to be the oxide of a metal called glucium."

William Allen Miller in his "Elements of Chemistry," London, 1860, starts the section of glucinum with: "Glucinum, the beryllium of the German writers."

These few references to some of the past chemical authorities—not to mention at length practically all the authors of textbooks on chemistry published in

English—together with those referred to on p. 418, Vol. 21, of *CHEMICAL & METALLURGICAL ENGINEERING*, carry weight enough to warrant our not having to use the word beryllium when speaking about "Glucinum, the beryllium of the German writers."

J. S. NEGRU.

New York City.

EDITOR'S NOTE:—Our aim in publishing the article on Glucinum was to give "An introduction intended to encourage the metallurgical and chemical development of the metal, its alloys and salts." It has led incidentally to the subject of chemical nomenclature and spelling, a subject which was not as solidly settled as Dr. Parsons might think. The ruling of the Council of the American Chemical Society to use "Beryllium" seems to be as unsatisfactory to some as the ruling of the American Association on the spelling and pronunciation of chemical terms to use "Glucinum" was to Dr. Parsons.

We have given quite a wide publicity to the work and aims of the newly created International Union of Pure and Applied Chemistry. We feel that the body of scientists and industrials composing the Union will consider the importance of a standardized chemical dictionary, and that the Council of the Union, of which Dr. Parsons is a vice-president, will meet soon to take up this subject and arrive at decisions which shall prevail.

Bureau of Mines Dedicates Pittsburgh Station

Appropriate exercises for the dedication of the Pittsburgh Experiment station of the U. S. Bureau of Mines were held at Pittsburgh on Sept. 29 and 30 and Oct. 1. The building, which is a large brick structure situated in the Schenley Park district near the Carnegie Institute of Technology, was opened for inspection of laboratories and exhibits. Formal program was participated in by the Pittsburgh Chamber of Commerce, which assisted materially in securing the station for Pittsburgh. Dr. S. B. McCormick, chancellor, University of Pittsburgh, delivered the invocation. Mayor E. V. Babcock gave an address of welcome in which he commented on the important aggregation of scientific and technical institutions in the Schenley district; namely, the Carnegie Institute of Technology, the University of Pittsburgh, the Mellon Institute and the Bureau of Mines.

ASSISTANT SECRETARY OF THE INTERIOR VOGELSANG
HANDING KEY OF BUREAU OF MINES BUILDING TO
DIRECTOR MANNING

Response was made by Mr. Alexander T. Vogelsang, First Assistant Secretary of the Interior, who represented Secretary Lane. Governor William C. Sproul also spoke and committed himself to an effort to secure State legislation bearing on the mining industry. Mr. J. Parke Channing represented President Winchell of the American Institute of Mining and Metallurgical Engineers and spoke at length on industrial relations. Mr. Van A. Bitler spoke on behalf of the president of the United Mine Workers of America. Following these addresses, Secretary Vogelsang presented to Director Manning the key to the building.

In the afternoon the entire party was taken to the experimental mine near Bruceton, Pa., where a coal-dust explosion was demonstrated. Other demonstrations consisted of the use of liquid oxygen as an explosive; the danger of an electric current making a circuit through metal powder cans; the danger of an open-flame exploding kegs of black powder; and the use of rock dust in the prevention of mine explosions.

Features of the two following days were contests between first-aid and mine-rescue teams which had come together from all over the country.

Sixteenth General Meeting, American Iron and Steel Institute

ANYONE attending the sixteenth general meeting of the American Iron and Steel Institute at New York City, Oct. 24, would have no doubt left in his mind how the membership as there represented viewed the matter of collective bargaining with labor unions. The president, Elbert H. Gary, outlined the meetings of the Washington conference between representatives of labor, capital and the public, just terminated, and reaffirmed his stand that the employer had a right to refuse to negotiate working conditions with any workmen's representative not actually employed by him. In this stand he said he was upheld by the management of his own corporation, by the stockholders—if a volume of letters from them was representative—and by the public at large. At least the body of steel-men assembled at the Hotel Commodore adopted unanimously and enthusiastically a resolution of confidence in their president, assuring him of their hearty support and belief in the correctness of his attitude.

But business and technology evidently do not mix, for the Chair's announcement that the meeting would listen to Van H. Manning talk upon the Bureau of Mines was the signal for three-quarters of the men in the over-crowded room to bolt for the door. As one of them remarked, "I don't know anything about these things, so I'll go." The faithful few who remained, however, heard some very stimulating papers, both in morning and afternoon sessions.

Résumé of Technical Session

Dr. Manning recounted briefly the history of the Bureau, showing how its first duties of safeguarding the health of the worker and our own natural resources have led to investigations in many fields; work on suffocating gases, on safe explosives, on fuel conservation, and the various researches of the many experiment stations. Especially interesting to iron and steel men is the work at Minneapolis, confined almost exclusively to ferromanganese and deoxidizers during war times, but now reaching out into the direct

reduction of iron ore and methods of utilizing our large deposits of low-grade and high-sulphur ores.

Dr. W. E. Ruder of the General Electric Co. reviewed the situation as regards "X-Ray Examination of Metals." He noted that the opacity of iron was so high that the use of the fluorescent screen, so handy in therapeutic work, is valueless for sheets more than 0.02 in. thick; still this method was usable in some cases to examine joints in assembled pieces. Photographic plates with an intensifying fluorescent screen were necessary when thicker metals were to be examined. Short-wave-length rays (so-called "hard" rays) give the best penetration, but require a very high e.m.f. for their production. Plant limitations and available apparatus make it impracticable to X-ray steel more than 2 in. thick; this requires 2½ hr. exposure by the best tubes with 10-in. spark gaps, utilizing current at 100,000 volts. In special laboratories, equipped with higher tension currents, considerably better can be done.

However, a great disadvantage lies in the fact that the rays themselves are considerably scattered in passage through sound metal, with a resultant fogging of the negative. Small defects near the skin are therefore more often shown than deep-seated blowholes of considerable size. Forgings are even more difficult to examine than castings, since their flaws usually consist of thin cracks. Prepared cracks in metal, when photographed under best conditions and in a known position, can be distinguished when 0.02 in. thick in 1½-in. metal, or a 0.007-in. crack can be found in ½-in. metal.

X-ray examination is evidently one method of investigating changes in a test-piece without damaging it in the least. Magnetic analysis, as discussed by R. L. Sanford of the Bureau of Standards, is another such method and in addition should become extremely useful as a test for uniformity with a chosen standard. The author noted that this test was being applied to shop conditions, as a method of comparing the quality of each piece produced to that of a master specimen. However, it required special and individual study to develop methods and equipment to test various types of manufactured articles. Thus, the curve-drawing instrument for testing rails, wire, or other continuous articles of uniform cross section has been known for two or more years. Another machine for testing rings is now under development, where the torque required to spin the ring in a uniform field is measured—any non-uniformity in the force represents a corresponding non-uniformity in the metal.

ELECTRIFICATION OF REVERSING STEEL MILLS

Wilfred Sykes of the Westinghouse organization presented an interesting discussion of "The Electrification of Reversing Steel Mills," illustrated by an excellent motion picture. He noted that the development of the reversing motor had been a simultaneous achievement of American and Continental engineers, the first installation on this side having started operations 12 years ago on a 2-high plate mill at the South Works, Chicago. Robert Hobson, the Canadian, has the credit of building the first successful blooming mill drive. Twenty-six reversing mills are now motor driven in America, comprising all types of reversing stands. While the first cost is more than for a steam installation, the fuel consumption is but one-half to

one-third. This is better appreciated by one who is familiar with the huge boiler plant required by a reversing steam engine when it is stated that the electric energy consumed by the motor drive is only 2½ times that of all the auxiliaries. Electricity is certainly a more economical energy to generate in bulk; the entire mill load is such that the peak of one operation fits in between the peaks of others, thus reducing the standby capacity needed, and the overall flexibility of the plant operation in general.

OPEN-HEARTH FURNACE AND PROCESSES

A series of queries was propounded by Henry M. Howe as to the excellence of somewhat standardized ideas on the open-hearth furnace and processes, queries designed as an outline for a future discussion on this general subject. Regarding furnace construction, he wished the economic and metallurgical advantages of tilting furnaces compared to those of the stationary type. Regenerator construction seemed illogical, and especially the checker design might be improved. How much watercooling of ports is economical in order to retain their shape? Are draft fans a paying proposition? The size of furnaces should also be carefully considered as regards the saving in fuel, soaking pit volume necessary, depth of bath, and refining action at slag : iron interface.

As regards the process itself, it appears that the composition of the slag is very important as to saving in iron oxide and its effect on the bath itself. Would it be better to charge iron oxide as ore rather than as rusty scrap or producing it during melting the iron? Would there be a real net saving by charging lime instead of limestone? Additions to the metal should be discussed in detail, in the light of the reaction products, and their fusibility, coalescing power, and tendency for liquation. In this connection, American practice of casting ingots at low temperature to produce a tough sheath should be carefully compared with foreign practice of casting at high temperature, allowing better liquation of impurities. Basic and acid processes should be discussed under truly comparable conditions, while the method of making steel in the ladle versus making it in the furnace should be argued at length. Compound processes and their relative advantages should also be considered in such a symposium.

TEMPERATURE MEASUREMENTS IN STEEL FURNACES

"Temperature Measurements in Steel Furnaces" was the subject of a paper by Dr. A. K. Burgess of the Bureau of Standards. Reviewing the history of pyrometry, he noted that high-temperature instruments were primarily developed following a request from the steel industry, but unfortunately, now that they have been perfected to a point of remarkable accuracy and convenience, the steel companies do not seem to be alive to the commercial possibilities of the instrument. Thus, practically instantaneous temperatures can be taken at 5-sec. intervals to an accuracy of 5 deg. at 1500 deg. C. Yet practically all the published temperature observations during the steel melting process have been taken by independent research organizations or pyrometer manufacturers. What is now needed is a study of the furnace, bath, and flame temperatures throughout the entire steel-making cycle co-ordinating temperature with time, and chemical

and physical changes in the slag and metal. Such information should be invaluable, not only to theoretical but to practical metallurgy.

MANUFACTURE OF INGOTS FOR LOCOMOTIVE TIRES AND ROLLED WHEELS

Lawford H. Fry, of the Standard Steel Works Co., discussed "The Manufacture of Ingots for Locomotive Tires and Rolled Wheels." His company has reverted to the earlier practice of casting individual ingots for each wheel or tire, weighing from 250 to 1900 lb. They found great difficulty in making these small ingots sound, free from blowholes and with no appreciable pipe, yet they continued their efforts, since success meant a reduction in scrap and crop ends of perhaps one-half. Steel, in the first place, must be properly made, and evolve just enough gas to counteract the contraction on cooling, and yet not enough to cause a rise in the top surface. The mold design is important; they use an octagon ingot with straight sides, whose height is from 60 to 100 per cent of the diameter across flats. The mold itself must be thick-walled at the base to cause rapid chilling at that point. Topping material thrown on the liquid metal is a very important detail. This so-called "pipe-eliminator" should not carburize the metal appreciably, but should be finely divided for blanketing effect, containing enough volatile for ready ignition, yet enough slow-burning fixed carbon to keep the top hot, and sufficient ash to separate metal and carbon with little delay.

In pouring these small molds, they are first ranged on the pit floor in 5 long rows, spanned by a gantry. A 50-ton ladle on this gantry fills two molds to a chalk mark simultaneously through two bottom nozzles, then the ladle is moved to each of the four remaining rows before the gantry shifts its position. Quick and extremely skillful work is evidently necessary.

Program American Institute of Chemical Engineers

Twelfth Annual Meeting, Dec. 3-6, 1919, Savannah, Georgia. Headquarters—Hotel DeSoto.

WEDNESDAY, DEC. 3

Meeting at Hotel DeSoto

9:30 A.M.—Address of welcome by Hon. Murray M. Stewart, Mayor, City of Savannah.

Response by President Little.

Business session.

Canvass of ballots for officers

Reports of officers and council.

Reports of committees.

10:30 A.M.—Reading of papers.

Report of committee on chemical engineering education and discussion of Dr. Charles E. Mann's report on a study of engineering education,

Prof. J. R. Withrow

Development of Some Southern Industries,

R. K. Meade

Accident Prevention in the Mill. H. K. Moore
Illustrated by lantern slides.

Developments in Chemical Engineering,

A. E. Marshall

12:30 P.M.—Auto trip seeing Savannah and vicinity, with oyster roast and barbeque at Bethesda.

8:00 P.M.—Meeting at Auditorium.

Reading of papers.

Address by President Little—Chemistry and the South.

History and Development of the Cottonseed Oil Industry David Wesson

Illustrated by lantern slides.

THURSDAY, DEC. 4

9:30 A.M.—Steamer trip on Savannah River and Harbor. Steamer leaves Bull St. at 9:30 A.M. The following plants will be visited: Shipbuilding yards, cotton compressing warehouses, paper and pulp mill operating on Southern pine, using sulphate process. Diamond Match Co. Luncheon served on steamer.

8:30 P.M.—Russian Symphony concert and Emma Roberts, contralto, at the Auditorium.

FRIDAY, DEC. 5

Meeting at Hotel DeSoto.

9:30 A.M.—Business session.

10:00 A.M.—Reading of papers.

Absorption Tower Packing Resistance to Gas Flow,

F. C. Zeisberg

Illustrated by lantern slides.

An Analysis of the Explosion Process of Recovery of

the Soda Salts from Black Liquor. . . . H. K. Moore

Recovery of Pyridine Bases at By-Product Coke

Ovens. F. E. Dodge and F. H. Rhodes

Double Pipe Heat Exchangers. . . . George A. Richter

The Phosphate Problem. Wallace Savage
12:30 P.M.—Luncheon.

2:00 P.M.—Auto trip to plant of Southern Cotton Oil Co., including inspection of crude cottonseed oil mills, preparation of lard compounds and hydrogenation of oils, and electrolytic plant, and a visit to the fertilizer plant of the American Agricultural Chemical Co. The manufacture of sulphuric acid by the chamber process and phosphate, as well as mixed fertilizer, will be shown.

7:00 P.M.—Subscription dinner at Hotel DeSoto.

SATURDAY, DEC. 6

9:00 A.M.—Special trips for small parties to various points of interest will be arranged.

LADIES' PROGRAM

WEDNESDAY, DEC. 3

11:00 A.M.—Meet with reception committee at Hotel DeSoto.

12:30 P.M.—Auto trip seeing Savannah and vicinity, with oyster roast.

8:00 P.M.—Meeting at Auditorium.

THURSDAY, DEC. 4

9:30 A. M.—Steamer trip on Savannah River and Harbor. Steamer leaves Bull St. at 9:30 A.M. Luncheon served on steamer.

8:30 P.M.—Russian Symphony Concert.

FRIDAY, DEC. 5

12:30 P.M.—Luncheon.

2:00 P.M.—Auto trip to plant of Southern Cotton Oil Co. and a visit to the fertilizer plants of the American Agricultural Chemical Co.

7:00 P.M.—Subscription dinner at Hotel DeSoto.

Dr. R. B. Moore Appointed Chief Chemist of the Bureau of Mines

DR. CHARLES L. PARSONS, chief chemist and chief mineral technologist of the Bureau of Mines, Department of the Interior, has tendered his resignation, effective Nov. 1, to take up work as a consulting chemist in Washington and to give more time to the affairs of the American Chemical Society, of which he is secretary.

Dr. Parsons was appointed chief chemist of the Bureau of Mines in 1911, going to Washington from New Hampshire College, where he was director of the chemical department. He immediately initiated important researches and sought to show how the results of scientific inquiries could be applied to methods of producing and utilizing minerals. One of his first undertakings after assuming general supervision of the work on mineral technology was the prepara-

and nitrates by synthetic methods. In this he was eminently successful, as the methods and apparatus developed have no equal in this country or in Germany for low cost of installation, high efficiency, and cheapness of product. In connection with his work on nitrates, Dr. Parsons was sent to Europe by the War Department in the fall of 1916 to study the problem of nitrogen fixation. The report he made on his return was used as the basis of the extensive program subsequently carried out by the Government in its nitrate plants. Dr. Parsons, however, has consistently advocated the Haber, or synthetic ammonia, process for producing nitrates as opposed to the arc, or cyanamide, process.

Late in 1917, at the request of the War Department and under a co-operative arrangement between it and the Bureau of Mines, Dr. Parsons undertook the designing and construction of a plant for the manufacture of sodium cyanide to be used as a basic material in the manufacture of certain war gases. Under an

DR. CHARLES L. PARSONS

Copyright, Harris & Ewing, Washington, D. C.
DR. R. B. MOORE

tion of a report on mineral wastes. (See U. S. B. M. Bulletin 42.) In connection with this general view of the mineral industries Dr. Parsons took up the study of fuller's earth and its use in refining oils. Since the publication of his results in 1913 in Bulletin 71 of the Bureau of Mines, the utilization of American fuller's earth has largely increased.

Dr. Parsons next gave his attention to radium, its recovery from its ores, and its use in the treatment of disease and in the investigation of physical and chemical laws. (See U. S. B. M. Bulletin 104.) Incidental to his work on radium Dr. Parsons personally devised in the laboratory and put into plant operation a method of producing black oxide of uranium and sodium uranate, which reduced the cost of making this substance from 75c. to less than 10c. a pound.

When early in 1916, as a result of the war in Europe, a shortage of Chilean nitrates confronted American manufacturers of fertilizers and explosives, Dr. Parsons gave attention to the production of nitric acid

allotment of \$2,800,000 from the War Department, this plant was erected at Saltville, Va., within 10 months from the day engineering work began, and was completed eight months after construction started. For work on this plant the War Department assigned 21 officers and 350 men to be under Dr. Parsons' direction. The plant functioned well from the start and produced cyanide, under war-time conditions, at a cost of 20c. a lb., or two-thirds of the lowest price at which cyanide could be purchased in open market.

After the United States entered the war, Dr. Parsons served on a number of Government boards. He was a member of the Nitrate Commission throughout the war, a member of the advisory board on war gases, chairman of a joint committee on the use of zirconium in steel, and was constantly consulted by the War and Navy Departments on many important problems. He organized and completed, with the aid of the Bureau of Mines and the American Chemical Society, a census of the chemists of the country, thus

making their mobilization easy. The Chemical Warfare Service was, in a sense, the outgrowth of this undertaking. The Ordnance Department of the Army obtained most of its chemical personnel from this source. As an outcome, more than 400 chemists were detailed for chemical work during the war.

Dr. Parsons was recently selected vice-president for America of the International Union of Pure and Applied Chemistry. He has been Secretary of the American Chemical Society since 1907, the Society increasing from 3300 to 13,700 members during that period.

Dr. R. B. Moore, who succeeds Dr. Parsons as chief chemist of the Bureau of Mines, has been known to the scientific world here and abroad for many years past by his important works, especially on radio-activity, rare gases and rare metals. He first became a Government official in 1911, when he resigned the position as professor of chemistry at Butler College, Indianapolis, Ind., to accept the position as assistant chief of the division of chemical and physical investigations, U. S. Bureau of Soils, Washington, D. C., but remained only one year, being transferred to the U. S. Bureau of Mines in 1912 as physical chemist in charge of the chemistry and metallurgy of rare metals, with headquarters in Denver. Three years ago these headquarters were transferred to Golden, where the

work has been continued in co-operation with the Colorado State School of Mines.

Dr. Moore's most important contributions to science are: An investigation of the heavy constituents of the atmosphere in order to see whether any new elements exist heavier than xenon. This work was done in Sir William Ramsey's private laboratory with Sir William. A determination of the densities of krypton and xenon. An investigation (with Herman Schlundt) of the radio-active properties of the waters of the Yellowstone National Park, in order to see whether localized quantities of radio-active material might be responsible for the thermal activity. He helped in the development of the potash resources of the country. He was directly in charge of the radium work of the Bureau of Mines and of the radium plant in Denver with which the Government produced about a million dollars worth of radium during its experimental work. He was in general charge during the war of three experimental helium plants operated under the control of the Bureau of Mines, and of the helium research laboratory. In addition he is the author of various papers in connection with radio-activity, the rare gases, and rare metals.

Judging from his past activities we can feel confident that he will fulfil ably and to the satisfaction of all his important functions and tasks.

Chicago Meeting, Electric Furnace Association

THE Electric Furnace Association, which met in Chicago Sept. 22, brought together some of the foremost electric steel men of the United States and Canada. The purpose of the Association is to bring out the superior quality of products made in the electric furnace. An interesting discussion of this subject occurred. The Association is the outgrowth of a meeting held in New York last April, which was attended by electric furnace men and at which time it was recognized that there was a great need for closer co-operation among the electric furnace designer, the power engineer and those who operate electric furnaces. The Association is not an offshoot of any other society, and its policy will be to co-operate with all other societies and associations that are interested in electric furnaces or the products of electric furnaces.

BETTER STEEL AND GREATER SAFETY THE DEMAND

There were about sixty present at the meeting. H. C. Weidenthal read a paper in which he pointed out the great demand for better steel in the automotive industry and indicated the increased demand for electric steel in that field. He recited the great need for greater factors of safety in the vital parts of automobiles, trucks and tractors and showed that the electric furnace would be called upon to supply steel of the proper quality.

In response to a demand for data on electric furnace products the Association has gathered together some information in regard to the high quality of electric steel and issued it in the form of a booklet. Those who attended the meeting commended this effort, and quite a large number of the booklets were requested by those present. In addition to data on quality, the booklet

also contains some statistics on the growth of electric steel production.

A permanent organization was effected and the following officers were elected:

President, Acheson Smith; vice-presidents, C. H. Booth and W. E. Moore; secretary, C. G. Schluederberg; treasurer, F. J. Ryan. The address of the executive office of the Association is Post Office Box 616, Niagara Falls, N. Y.

The next meeting of the Association will probably be held next spring in conjunction with some of the national technical societies, and it is probable that a symposium on the subject of power for the electric furnace will be the principal feature of the meeting. This will give an opportunity for the power engineer and the electric steel men and others operating electric furnaces to discuss thoroughly the power-service problem of the electric furnace. Although the present meeting was largely devoted to electric steel, it is the intention of the Association to take up the subject of non-ferrous metals and other materials made in the electric furnace.

SOME IN ATTENDANCE

Among those who attended the meeting were L. E. Howard, of the Simonds Manufacturing Co.; L. M. Reed, Haynes Stellite Co.; A. C. Jones, of the Electric Steel Co., Chicago; W. F. Graham, of the Spicer Manufacturing Corporation; E. S. Gardner, Illinois Steel Co.; Edward T. Moore, Halcomb Steel Co.; F. W. Chapman, of the Standard Steel Castings Co.; J. M. Blake, American Manganese Steel Co.; A. Trevor Jones, American Steel Foundries; A. H. Miller, Midvale Steel & Ordnance Co.; A. U. Tirbutt, Manitoba Steel Foundries, Ltd.; Mr. Starr, Pattibone Mulliken Co., of Chicago, and many others interested in the electric steel industry.

Philadelphia Meeting, Institute of Metals

A Full Synopsis of Several Important Groups of Papers, on the Physical Properties of Zinc and Nickel, on the Constitution and Heat Treatment of Duralumin, on the Manufacture of Special Wire for Electrical Purposes, and on Physical Properties of Gun Metal

A WELL attended meeting of the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers was held, as is the custom, in conjunction with the American Foundrymen's Association. Several important groups of papers were presented, and between meetings the members were entertained by excursions to Hog Island, the Baldwin Locomotive Works, local foundries or in viewing the many shrines of Revolutionary days. In connection with the joint meeting, the annual exhibition of foundry equipment was held at the Commercial Museum, which proved to be an admirable display in all respects. One was chiefly struck by the showing of machine shop tools, both in number and variety, ranging from a simple drill press to the most intricate automatic machine for a half-dozen different simultaneous operations—a machine one would scarcely expect to find in an ordinary foundry.

PHYSICAL PROPERTIES OF NICKEL

A valuable compilation of information on the "Physical Properties of Nickel" was presented by J. F. Thompson in a paper prepared with the collaboration of the late David H. Browne, of the International Nickel Co. They emphasize that "nickel" is a rather flexible term, denoting a metal whose physical properties are widely influenced by its composition and treatment, and being exceedingly difficult to prepare in a pure state. A brief résumé of metallurgical methods is given, further emphasizing the fact that results reported for "nickel" may refer to one of five different classes: sponge, Mond process, cathode crystals, Orford process, or malleable nickel.

Nickel itself melts at 1451 deg. C., has a magnetic transformation like iron, but no other allotropic modifications. The loss of magnetism occurs at 340 deg., but is by no means abrupt. It absorbs carbon by cementation, the carbide Ni_3C acting very much like cementite, in that it forms a eutectic at 1328 deg. C., and deposits graphite readily. Graphite is deleterious, but the carbide very beneficial in increasing hardness and strength. Manganese is purposely added up to 2 per cent to increase the fluidity and ease of working. Iron less than 1 per cent, silicon less than 0.25 per cent and cobalt up to 1 per cent do not harm nickel, but sulphur should be held as low as possible. Nickel may be welded electrically. If a melt of nickel is vigorously stirred by a stick of magnesium plunged entirely beneath the surface, it will be free from gaseous blow-holes and can be worked hot or cold. Hot shortness occurs above 1200 deg. C. Proper annealing range is from 750 to 900 deg. C., but one should be careful not to overheat, and to use sealed boxes with a reducing atmosphere. Oxide is removed by pickling only with great difficulty by sulphuric and chromic acid at 70 deg. C.

ROLLED AND DRAWN ZINC

Professor C. H. Mathewson of Yale University and C. S. Trewin and W. B. Finkeldey of the New Jersey Zinc Co. presented an extensive paper covering "Some Properties and Applications of Rolled Zinc Strip and Drawn Zinc Rod," in which they presented a quite complete view of the subject difficult to abstract in small space. At the outset it should be pointed out that ordinary tensile tests on zinc are somewhat difficult to interpret, since the metal fails at a lower load than the maximum; therefore the rate of loading has much to do with results. Test specimens also show a permanent set under small loads, which increases with a repetition of the same load, consequently there is no possibility of computing a true modulus of elasticity—the substance does not obey Hooke's law.

Viewed in the light of the amorphous theory, as recently enunciated by Jeffries,¹ the temperature of equal cohesion between amorphous and crystalline phases of purest zinc (0.004 per cent Pb, 0.005 per cent Fe) is in the neighborhood of 40 deg. C. That is to say, if this metal is rolled at temperatures somewhat above 40 deg., it will spontaneously recrystallize during grain deformation, in which case there is no hardening due to working. In fact, strain hardening induced by working at temperatures of zero deg. and lower is not permanent unless the metal is permanently refrigerated. If the amorphous phase in pure zinc at room temperatures is conceived to be somewhat plastic, the fact that this metal yields more readily to slowly than to rapidly applied stress (like pitch or hot glass) can be explained. Practically all alloying metals raise the equi-cohesive temperature of zinc and stiffen the amorphous phase even when added in tenths of a per cent. Thus sheet rolled from common spelter can be raised from 20,000 to 40,000 lb. per sq.in. by strain hardening, the rods

¹Bulletin, A.I.M.E., No. 146, p. 575 (February, 1919).

are much stiffer under slowly applied loads, and more than a week at 100 deg. C. is required for a full anneal.

The above remarks make clear the peculiarities in rolling-mill practice. Starting with a coarsely crystalline brittle slab with very low strength, a reduction of 50 per cent at a temperature of 150 to 100 deg. C. will produce a bar with an ultimate strength of 18,000 lb. per sq.in. and an elongation of 50 per cent. Theoretically, these physical characteristics are due to a fine crystalline structure, the cleavage surfaces of the individual grains—through which fracture passes—being supported by the intergranular plastic amorphous material and by their own dissimilar orientation. Rapid grain growth prevents much change in physical properties up to a reduction of 90 per cent. Later careful rolling at lower temperatures will produce a harder material, increasing the ultimate to 30,000 lb. and decreasing the elongation to 40 per cent.

Annealing practice again is quite distinctive. As usual, the grains grow upon annealing strained specimens—larger grains result from a higher (or longer) anneal. Twinned structure, so common in brass, is absent, although moderate strains cause narrow blocks of material in the grain to change in orientation, this being a form of mechanical twinning. When annealing hard drawn zinc at low temperatures, there appear to be few centers of recrystallization active; the result is that if time be given all distorted grains will be absorbed into a few coarse crystals. At higher temperatures, more nuclei are present, and the result is a finer grain.

The phenomena just described are quite in line with Jeffries' principal generalizations dealing with selective growth. Thus, the coarsest grains are found at an early temperature of recrystallization or in the equiaxing range, and when the equiaxing range is passed rapidly, as must be the case when the samples are dipped directly into an oil bath at a high temperature, smaller grains are formed.

Medium hard-drawn zinc upon reheating gives about the same results, although the selective growth of recrystallized grains does not start so soon. Once started, growth is rapid until recrystallization is complete, then a very slow growth ensues on continued anneal. Soft rolled material on annealing merely absorbs the smallest particles into their neighbors.

In addition to this general discussion the authors publish a wealth of experimental data in tabular and graphical form. In their work they developed a dynamic cupping machine to test the availability of a sheet to a drawing operation. The ordinary slow-action test for ductility gives a fictitiously high number of merit for hard strip zinc, owing to its plasticity under slowly applied loading. Actual plant operations are performed with considerable speed, however, and dead soft zinc under such impact test is practically unaffected by the speed of working, giving values about midway between hard and annealed 70 : 30 brass.

DURALUMIN

A very notable series of four papers on aluminum-rich alloys with magnesium and copper were presented by Dr. P. D. Merica and Dr. Zay Jeffries and their associates. These light, strong alloys have become quite well known within the past ten years under the name of duralumin. They are capable of rolling and forging, and under proper heat treatment will develop quite remarkable properties, chief of which is the progressive hardening which takes place at room temperatures following a quenching.

METALLOGRAPHY

In the first of these, P. D. Merica, R. G. Waltenberg, and J. R. Freeman of the Bureau of Standards present the results of studies on the solubilities of certain metals and their compounds in nearly pure aluminum in a paper entitled "Constitution and Metallography of Aluminum and Its Light Alloys With Copper and Magnesium." The study was complicated by the fact that 100 per cent aluminum metal is at present unavailable (although the Bureau of Standards is now well along toward its production in quantities sufficient for investigative purposes), commercial aluminum containing as much as 0.2 to 0.5 per cent each of iron and silicon. Copper-aluminum alloys have already been shown to develop a eutectic between CuAl and Al containing about 32 per cent copper by weight and melting at 540 deg. C. Chill-casting even low-copper alloys gives a non-homogeneous, mottled structure when examined under the microscope; consequently annealing experiments by the authors were used to develop the limits of solid solution of CuAl at equilibrium, as shown in Fig. 1. Within the limits of solid solution the microscopic appearance at 300 diameters is a uniform fine grain (sorbic) due to impurities contained in the available aluminum; but just beyond the line bc , excess CuAl appears as white rounded particles in this ground mass (etching in 0.1 per cent NaOH plus 10 per cent alcohol). This precipitation and segregation into microscopic particles requires very slow cooling from 500 deg., and as much as 1 per cent magnesium was found to have no influence on the solubility curve.

Again, in regard to the binary system aluminum-magnesium, the authors note that previous researches show a eutectic between Al and Mg_2Al_3 melting at about 460 deg. C. and containing 36 per cent Mg. A set of annealing experiments similar to those with low-copper

FIG. 1. PORTION OF THE EQUILIBRIUM DIAGRAM OF THE Cu-Al ALLOY SERIES SHOWING THE SOLUBILITY CURVE Cu-Al_2 IN ALUMINUM

FIG. 2. PORTION OF THE EQUILIBRIUM DIAGRAM OF THE Mg-AL ALLOY SERIES SHOWING THE SOLUBILITY CURVE Mg_2Al_3 IN ALUMINUM

alloys now establishes the solubility curve *be* of Fig. 2. After an etching with 5 per cent NaOH solution, Mg_2Al_3 shows as clear islands scarcely differentiated from the ground mass except by a boundary line (Fig. 3). The few dark particles in this micrograph have an easily distinguishable and characteristic deep blue color, its amount increasing slowly if at all with an increase of magnesium content beyond about 1 per cent. This is believed to be Mg_2Si , a well developed compound in that binary system, or a silicate or complex compound containing Mg, Si, Fe and Al.

Guyer, studying the iron-aluminum system, has already shown that the compound $FeAl_3$ forms a eutectic with aluminum at 649 deg. C., containing between 1 and 2 per cent iron. Observations on commercial aluminum, containing as low as 0.15 per cent iron, show a large amount of light bluish constituent, both in the form of distinct islands and scattered uniformly through the aluminum grains (Fig. 4). It can be differentiated

from $CuAl$, by its darker color, also in the fact that it turns brown on long etching with dilute alcoholic NaOH solution (Fig. 5). Darker markings ordinarily appear in the eutectic islands when silicon reaches 0.20 per cent, corresponding to the simultaneous appearance of a constant arrest at 610 deg. C. This constituent X is possibly a compound containing silicon and iron, since it is known that Si and Al alone form no compounds, but a eutectiferous series with a minimum melting point at 576 deg. C. and 15 per cent silicon. An additional arrest in the cooling curves at 576 deg. C. appears only with relatively high amounts of silicon alloyed with commercial aluminum. Owing to the facts that $FeAl_3$ is so insoluble in Al and that the best obtainable aluminum will have a few hundredths per cent of iron, the metallic crystals forming the ground mass of all aluminum specimens will appear granulated by the ever present iron eutectic.

LOW TEMPERATURE HARDENING

With the above information as to the constitution of duralumin well in hand, it is possible for Merica, Waltenberg and Scott to present a reasonable explanation of its hardening on low-temperature annealing in their paper on "The Heat Treatment of Duralumin." No difference in microstructure can be observed after aging, but thermal analysis gives a little light. An irreversible evolution of heat occurs at from 250 to 275 deg. C. in samples which have been quenched but not aged, which phenomenon is missing from annealed or aged metal; evidently stable phases have been formed by time and temperature, missing in the quenched metal.

It has been shown by many previous investigations, and confirmed by the authors, that aluminum undergoes no transformation in the solid state between ordinary temperatures and its melting point. No other phase changes would occur in the main mass of duralumin, (the grains of solid solution), therefore, except those of solution or precipitation of $FeAl_3$ of the X compound, of $CuAl$, of Mg_2Al_3 or of Mg_2Si within the grains. Commercial aluminum, which contains the same amounts of $FeAl_3$ and of the X compound as does duralumin, is not altered by heat treatment as is duralumin, nor does it show a reverse heat effect upon heating as does the latter. This heat effect must, therefore, be due to the precipitation either of $CuAl$, Mg_2Al_3 , or Mg_2Si . But the alloys containing only magnesium, in amounts up to 3 per cent, also do not harden upon aging. There remains

FIGS. 3 TO 5

Fig. 3. Mg-Al alloy, annealed 20 hr. at 400 deg. C and then quenched. Mg 17.1 per cent. Etched with 5 per cent NaOH. $\times 300$. Fig. 4. Commercial aluminum (Si 0.20 per cent, Fe 0.50 per cent), showing eutectics of $FeAl_3$ and of constituent X. $\times 1000$. Fig. 5. $FeAl_3$ eutectic, and fine particles throughout groundmass. $\times 1255$. Mg 1 per cent, Cu 1.6 per cent, Fe 0.3 per cent, Si 0.26 per cent.

only the precipitation of CuAl_3 , with which to explain this heat effect.

The theory is the more reasonable when found to check with the observed work on solubility of CuAl_3 in aluminum. Hardening or aging is therefore ascribed to the precipitation of the then insoluble CuAl_3 from its solid solution, temporarily held in unstable equilibrium by rapid cooling. However, even on aging at 100 deg., the temperature is so low that molecular migration and coalescence of the precipitated particles to a microscopic aggregate is impossible; consequently aged and freshly quenched specimens show no marked difference optically. The phenomenon is in fact quite similar to the hardening on low temperature anneal of some high-carbon or tungsten steels by precipitation of highly dispersed cementite from austenite. Aluminum-zinc and aluminum-magnesium-nickel alloys also harden upon aging—in each case a demonstrated decreasing solubility at lower temperatures of a constituent is probably responsible. In duralumin, the presence of magnesium, although in itself not capable of giving the aging effect, accelerates the influence of copper, possibly by lowering the melting temperature of the FeAl_3 eutectic, which often wholly encloses masses of CuAl_3 (Fig. 5), in this manner indirectly allowing the latter to diffuse more readily into the aluminum.

Thermal analysis of duralumin as a whole is quite complicated, since six probable binary eutectics occur, to say nothing of possible more complex aggregates.

	Deg. C.
$\text{FeAl}_3 + \text{Al solid solution}$	640 to 650
$\text{Si} + \text{Al}$	570 to 580
$\text{X} + \text{Al solid solution}$	610
$\text{CuAl}_3 + \text{Al solid solution}$	520 to 540
$\text{Mg}_2\text{Al}_3 + \text{Al solid solution}$	450
Mg_2Si	440

Temperatures are approximate and observed in the presence of both FeAl_3 and X eutectic.) Consequently thermal analysis is somewhat complex, as is shown in

FIG. 6. HEATING AND COOLING CURVE OF N-28 (Cu 4.98 PER CENT, Mg 2.41 PER CENT)

Fig. 6, this cycle repeating itself indefinitely. On first cooling a solid solution of CuAl_3 , first crystallizes, these crystals forming nearly the whole alloy and leaving only thin films and drops at the crystal boundaries. The walls of these cavities are then lined by the FeAl_3 , aluminum solid solution eutectic on decreasing tem-

FIG. 7. SPECIMEN OF N-28 CONTAINING Cu AND Mg, SHOWING ISLAND OF Mg_2Si (DARK) WITHIN ONE OF CuAl_3 (WHITE). $\times 650$

perature, until at about 500 deg. the binary eutectic CuAl_3 , aluminum solid solution crystallizes with the remainder of the first eutectic. Even later at 478 and 456 deg. Mg_2Si and perhaps some Mg_2Al_3 solidify in the remaining voids. Microscopically the result is as shown in Fig. 7, where the phenocryst is probably "negative CuAl_3 " rather than "positive Mg_2Si " (the striations on its face at least are not parallel to its edges). On reheating, however, the surface of contact between Mg_2Si and aluminum is so slight that the melting of the eutectic proceeds very slowly and is really merged in the upper arrest when CuAl_3 melts.

In addition to these most interesting theoretical considerations, the authors have collected and plotted a large amount of information regarding influence of manipulation and chemical composition upon the hardening phenomena. This could best be induced in an alloy of normal composition (Cu, 3 to 4.5 per cent; Mg, 0.4 to 1.0 per cent; Mn, 0 to 0.7 per cent) by a quenching from 500 deg. C., followed by an accelerated aging for 5 days at about 100 deg. C., or 2 days at 150 deg. C. Careful physical measurements on a quenched sample showed a slight discontinuity in the linear expansion on heating at about 250 deg. C., and a change in direction in the curve of electrical resistance at about 325 deg. C.

In connection with the above discussion, a note by Zay Jeffries presented to the British Institute of Metals at its September, 1919, meeting is pertinent. Referring particularly to the fact that there is a certain average size of precipitated CuAl_3 particle which produces maximum strength and hardness, Dr. Jeffries points out that the "smallest globule resolvable under a high power microscope contains about 2 billion molecules, consequently the phenomenon of aging may very well involve changes which cannot be observed. He considers the process in two stages; immediately after quenching, the excess CuAl_3 is precipitated, some of it having agglomerated into small particles, but more as single molecules having little or no adhesion with the particles of the matrix. Therefore the adhesion and consequently the strength and hardness of the metal are low. Moderate heat allows molecular migration; the dispersed molecules are attracted to the larger particles adjacent, impoverishing the matrix at the boundary. "This accom-

plishes two things, namely, it facilitates migration of CuAl, toward the globule by the forces of diffusion, and it reduces the number of CuAl molecules in the matrix at the boundary with the globule to normal saturation, which is the condition for maximum adhesion between CuAl, and the matrix." The cohesion of the matrix itself is increased by an increase in the normal forces in the space formerly occupied by the loosely held CuAl molecule. Thus the mechanical strength and hardness approach a maximum. "If the particles of CuAl continue to increase in size beyond a certain average and decrease in number, as in prolonged aging, at 200 deg., the cohesion decreases."

HEAT TREATING DURALUMIN CASTINGS

Duralumin in sheet or extruded products has for some time been commercially heat treated, a quenching from about 500 deg. C. showing an increase in hardness, especially after an aging of 4 days or more. Castings of the same composition [Cu up to 6 per cent, Mg up to 2 per cent, Mn up to 1 per cent, Si and Fe (as impurities in the commercial aluminum) up to 0.5 per cent each] have been investigated by Dr. Zay Jeffries and W. A. Gibson of the Aluminum Castings Co., who report in their paper on "Heat Treatment of Aluminum-Alloy Castings" that it is necessary to guard against oxidation of the somewhat porous castings from furnace atmosphere and quenching medium. When this is done, as for instance by heating in a bath of fused alkaline nitrates and quenching in oil, the strength and elongation are markedly increased and made much more uniform. Metallographically, this effect is shown to be due to the absorption of a network containing the compound CuAl. High-iron alloys also show needles of FeAl within the grains, but these remain unabsorbed to a large extent. Physical tests were made of a large number of melts in a study of chemical composition. In general, the addition of iron (up to 1½ per cent) is more beneficial to low-copper alloys (3 per cent Cu) than high (6 per cent Cu); in the latter case the beneficial results of heat treatment are especially marked. A low-copper alloy with 1.4 per cent iron shows an increase in tensile strength, but a decreased elongation up to 1 per cent Mg.

MECHANICAL PROPERTIES

Since the alloy duralumin is used to a great extent in airplane parts and in other machine parts requiring a combination of lightness and high strength, it was thought desirable to investigate the mechanical possibilities of the light alloys of two somewhat analogous ternary series. Messrs. Merica, Waltenberg and Finn of the Bureau of Standards did the work in co-operation with the Aluminum Company of America, and their results were presented in a paper entitled "Mechanical Properties and Resistance to Corrosion of Rolled Light Alloys."

Light aluminum alloys of several compositions belonging to each of the three ternary series aluminum-magnesium-copper, aluminum-magnesium-manganese, and aluminum-magnesium-nickel were rolled out into sheets and tested in tension as cold-rolled, after annealing, and after heat treatment, consisting of quenching from about 500 deg. C. and aging at ordinary temperature.

The tensile properties of the alloys of the aluminum-magnesium-copper series were superior in all conditions to those of the other series. They may be much improved by an appropriate heat treatment. The alloys

of the aluminum-magnesium-nickel series are also improved by heat treatment, but not in the same degree as the former series. The alloys of the aluminum-magnesium-manganese series are not improved by heat treatment.

Samples of representative compositions of each series were exposed to corrosion in the salt spray test, and the appearance of the samples was observed after exposure to the action of the salt spray for one and for two months. The alloys of the aluminum-magnesium-manganese series resisted corrosion, in general, better than those of the other series, and this observation agrees with other experiences in the corrosion of such alloys. The heat-treated specimens of the aluminum-magnesium-copper series, however, were but little inferior to those of the manganese series in their resistance to corrosion; the annealed and the cold-rolled samples of that series were the least resistant to corrosion of any of the alloys tested. Hard-rolled commercial aluminum corroded much more than any of the alloys. Annealed aluminum was more resistant to corrosion than the hard-rolled aluminum, but did not compare favorably with most of the alloys.

MANGANIN AND CONSTANTAN

Manganin, by virtue of its use in electrical instruments, must have a very small temperature coefficient of resistance and thermal e.m.f. against copper at room temperatures. Studies, described by F. E. Bash, research engineer of Leeds & Northrup Co., made to discover methods of commercial manufacture of this wire, formerly available from Germany only, developed the fact that exactly reproducible results could be had by melting 83 parts of electrolytic copper and 2.5 parts of electrolytic nickel in a magnesia-lined graphite crucible. After liquefaction, the melt is covered with charcoal, and 14 parts of thermit-manganese stirred in by a cool iron rod in two batches. There was then added 1.5 parts pure iron wire to the superheated melt, the alloy deoxidized by 0.1 per cent of magnesium, wired to the stirring rod, and immediately poured into iron molds. This melting practice is very important and guards against the introduction of silicon, which causes great variation in electric properties, and keeps the oxygen at a minimum. Annealing during working must be done in reducing atmosphere, or else the low-manganese skin removed by pickling before the final draw. If nickel is replaced by aluminum, somewhat better mechanical properties result, and the thermal e.m.f. is reduced to 0.3 microvolt. In any case a surface action, probably an oxidation, causes a slow change in the electrical properties with time, especially if the wire is oil-immersed.

An especially interesting paper by the same author on "Manufacture and Electrical Properties of Constantan" described the company's work in making that nickel-copper alloy to replenish its exhausted stock of imports. For its particular use it was necessary that new thermocouple wire should develop the same thermal e.m.f. against iron as the old stock, in order that calibrated dials on indicating and recording instruments would read correctly. In other words, at 1500 deg. F. the e.m.f. should equal the company's standard, or 47.40 millivolts within ± 1 per cent.

Preliminary laboratory melts synthesizing known analyses were first tried, and it was soon noted that practically the same e.m.f. was given by alloys of quite different analyses. Consequently an extended

investigation of the effect of physical treatment on the wire was undertaken, but with negative results, since it was demonstrated that no appreciable segregation occurred in the ingot, and the electrical characteristics were the same after working and annealing at various temperatures and in various atmospheres. Therefore the research veered back to the chemical analysis.

A study of melts made with electrolytic nickel and copper showed that their e.m.f.'s against ingot iron at 1500 deg. F. when plotted against composition gave a flat peak between 70 and 40 per cent copper. As a basis of further work, a 55:45 copper-nickel alloy giving 53.25 millivolts was selected as a standard ratio for the main ingredients. Keeping this constant and adding successive amounts of pure manganese, it was found that the e.m.f. dropped in direct ratio to the amount of addition, 3 per cent manganese lowering the value 9.5 millivolts. Likewise iron, silicon and carbon were tried, all giving linear reductions; 0.7 per cent iron lowering the value 7.7 millivolts; 0.7 per cent silicon 5.75 millivolts, and 0.7 per cent carbon 4.65 millivolts.

With this information it was possible to compute likely analyses which would give the desired e.m.f.; laboratory melts of this sort were tried. Sometimes the electrical properties were correct, but quite often were too high or low, due to scavenging and losses in manganese or silicon, or unavoidable addition of iron or carbon in the furnace work.

These small scale melts were made in a granular resistor furnace. In the center of the resistor was placed a No. 1 graphite crucible with the bottom sawed off. In the bottom was a thin layer of granulated carborundum. Crucibles gave much trouble. The ordinary graphite crucible put too much silicon into the melt, while a fire-clay crucible did not stand up well. Sand crucibles could not resist the furnace conditions. Aluminum was excellent as far as keeping the melt pure, but it was ordinarily good for only one melt, and not that if by chance it came in contact with the graphite walls at high temperatures. Quartz was wholly satisfactory and stood several melts. Electrolytic cathode cuttings were melted in a reducing atmosphere, and the thin film of oxide slag reduced by a pinch of carbon. Proper additions were then made, stirred in with a silica tube, and when liquefied the melt chill-cast in a $\frac{1}{2}$ -in. square ingot. This was rolled down to 0.1-in. square, annealed and tested electrically.

After this preliminary work, a regular 4-ton heat was made by the International Nickel Co., in an oil-fired open hearth. A number of different additions were made to 275-lb. ladles of metal, poured at about 2700 deg. F. into 57-lb. sand-cast test bars and a 200-lb. ingot. The analyses were remarkably constant, showing that by careful furnace work it was possible to hold the iron to within 0.05 per cent and the manganese to 0.10 per cent. E.m.f.-composition curves similar to those obtained in the laboratory resulted. Wires drawn from the ingots were made into 60-lb. coils, and each tested for e.m.f., varying from +1.6 millivolts to -1.3 millivolts from the standard, although 101 out of 149 coils were within the tolerance ± 0.5 millivolts. From later melts aggregating 40,000 lb. only 25 per cent was accepted, due to small variations in impurities such as crept into the laboratory melts. The only way such wire can be made is to predict as close an analysis as possible and then test each coil separately for thermal e.m.f., rejecting any which falls without the desired limits.

PAPERS ON GUN METAL

C. P. Karr of the Bureau of Standards reported on a test among five foundries on the strength of Government bronze (88 Cu, 10 Sn, 2 Zn). One of the foundries prepared ingots from virgin metal, which were then divided among the co-operating concerns. A first series of test-bars, cast even under rather definite instructions, gave rather wide variations; merely an example of the extreme care necessary to get comparative tests on this alloy so sensitive to moderate changes in gating, molding, or temperature. After discussion of results, a new set of bars were cast in a standard mold similar to Fig. 8, poured flat with reservoir gates made in green sand. The core-sand mold itself had linseed oil as binder and was baked in a core-oven. Even with this practice, considerable variation in physical properties from the same foundry were found, and even greater variation in bars from different

FIG. 8. CORE BOX USED IN MAKING SHOULDERED TEST-BARS

plants. In general, coarse sand allowing ready gas escape will give high strength, while thin castings poured hot will have low elongation. Results follow:

Composition	Number of Specimens	Proportional Limit	Tensile Strength, lb. per Sq. In.	Elongation in 2 In., Per Cent.	Reduction in Area, Per Cent.
88 Cu, 10 Sn, 2 Zn	30	12,200	38,900	25.3	21.0
		1,600	$\approx 5,250$	≈ 5.9	≈ 4.7
88 Cu, 8 Sn, 4 Zn	26	11,000	39,400	32.0	25.0
		1,650	$\approx 4,200$	≈ 7.0	≈ 4.6

A research was undertaken by Prof. C. F. Swart of the University of Michigan to discover whether quenching 88:10:2 bronze will increase or decrease its strength and ductility, a point variously reported by previous investigators. In a paper entitled "Influence of Heat Treatment on Gun Metal," he notes that furnace, air-, or water-cooling after a 30-min. anneal at 600 deg. or less will equal or better the properties of sand-cast test bars, but the specimens quenched in water from higher temperature anneals showed lower tests and the fracture had a coarsely crystalline band some 2.5 mm. thick around a fine-grained center. Microscopic examination of etched samples in the sheath showed irregular crack-like markings thought to be strain lines, and in specimens which were turned down to remove this strained surface almost normal values for strength and ductility were restored.

Considerable difference in opinion as to this question developed in the meeting. Dr. Karr of the Bureau of Standards said that their high results on quenched bars were not due to machining off the skin, as suggested by the author, as all shaping was done prior to heat treatment. R. F. Wood said his experience indicated that the strength of this bronze could be reduced from 40,000 to 18,000 lb. per sq. in. by quenching after annealing at 700 to 800 deg., even though the piece be air-cooled

to no color before immersion. P. E. McKinney observed that practice at the Naval gun factory demonstrated that a sound red-bronze casting could be strengthened by annealing. Large castings must then be quenched to prevent large crystalline growth of the alpha constituent, when annealing must follow to relieve cooling strains. He was of the opinion that cracking in such metal was due to careless handling of the piece at a very tender stage rather than to quenching stresses.

In order to conserve the war-time supply of tin, it was suggested that an alloy containing 90 per cent Cu, 6.5 per cent Sn, 1.5 per cent Pb, and 2 per cent Zn be used in place of the 88:10:2 gun metal, since the former alloy was said to have better qualities in almost all respects. H. F. Staley and C. P. Karr investigated this and a number of analogous compositions at the Bureau of Standards, and have reported their findings in a paper entitled "Physical Properties of Certain Lead-Zinc Bronzes." Of the nine alloys investigated it was actually found that only two or three are somewhat superior to gun metal in ductility, and are about equal to it in other respects. Substitution of lead above $\frac{1}{2}$ per cent for zinc or tin, or substitution of zinc above 2 per cent for tin, was found to lower the quality of the castings. Since the compositions fall within the α solid solution field of the copper-tin diagram (regarding zinc as equal to $\frac{1}{2}$ part of tin, and lead as an insoluble impurity), heat treatment has little effect upon the properties of the bars. In the discussion it developed that the substitute analysis recommended had proved very successful for small hydraulic valves. It was also urged that a series of tests on nickel-bearing bronzes be immediately undertaken, in view of the large quantity of copper-nickel shell-rotating bands now available at a low price.

Phosphorus and Sulphur Limits in Steel

Representatives of the American Society of Testing Materials held a meeting with members of the metallurgical section of the Bureau of Standards, representatives of the U. S. Railroad Administration, steel manufacturers, the Shipping Board, automobile industry and other steel consumers in Philadelphia, Oct. 14, and agreed upon an investigative program covering the question of phosphorus and sulphur limits in various grades of steel.

A tentative program of laboratory investigations and service tests has been mapped out, involving the co-operation of steel manufacturers, users and the Bureau of Standards. The economic importance of this question is recognized by all of the co-operating institutions, due to changing conditions relating to several factors of steel manufacture, such as the gradual increase of phosphorus in available iron ores, the large amount of high sulphur scrap and the poor quality of fuel with its high sulphur content.

According to the tentative program, the test for sulphur will be made first on rivets, steel tubes, etc., and secondly on plates and structural shapes, including boiler plates.

Commercial Fair to Be Held at Brussels

The first annual commercial fair of the city of Brussels will be held April 4 to April 21, 1920. Only allied and neutral countries will be allowed to participate.

Chicago Section Meeting, American Chemical Society

THE regular meeting of the Chicago Section of the American Chemical Society was held in the Monadnock building, Chicago, at 8 P. M. Friday, Oct. 24, with the usual large number of members in attendance. The report of the executive meeting was read, the principal feature of which was the proposal of Dr. William A. Noyes for president of the American Chemical Society at the next election. The report of the finance committee revealed extensive preparations for a real welcome to the visiting members of the Society at the annual meeting next year. Dr. L. V. Redman, chairman of the Chicago Section, cited the performance of the Philadelphia Section, in September, as an example of what may be done along those lines of warm hospitality. The report of the membership committee showed the acquisition of many women members. Furthermore, many of these members are in regular attendance at each meeting.

The paper of the evening was presented by Dr. C. A. Tibbals, associate professor of inorganic chemistry, Armour Institute, and late Captain, Ordnance Department, U. S. Army. An abstract from Dr. Tibbals' paper follows:

EXPLOSIVES RESEARCH AND TESTING

The Picatinny Arsenal is an old Government establishment, having been started in the early '80s for work on the production of propellants and high explosives. At the beginning of the war there was in operation there a black powder factory, producing a standard powder for the Government and incidentally the best black powder used during the war; and an ammonium picrate plant, making the Government Explosive D, the only practical high explosive of which we had knowledge at that time. This plant was supplying the peace-time requirements for high explosives. These two plants had control, inspection division and very small research laboratories.

The laboratories were taken as the nucleus for the organization of an adequate research unit. The problems which confronted the organization were (1) large quantity production, (2) shortening of time from explosive plant to field, and (3) the development of a flashless propellant. This last item was needed to prevent revelation of battery positions to the enemy during night firing. Smokeless powders produce a bright flash. The new requirement was met by the incorporation of certain powders in the smokeless charge which reduced the temperature of the gases of explosion by the time they reached the muzzle of the gun. They were in successful use in the field at the close of the fighting and were known as P. A. No. 1 and P. A. No. 2.

The arsenal made high explosives, loaded and used them in shells of all sizes, hand and rifle grenades, trench mortar shells and aerial drop bombs. High explosives were tested for (1) stability, (2) sensitiveness, (3) hygroscopicity, and (4) surveillance.

After the laboratory routine was completed the power of explosion was noted by several methods, among which was the sand test.

Very few of the many proposed explosives were recommended.

Symposium on Industrial Alcohols

First Fall Meeting of New York Section of American Chemical Society—Future of Industrial Alcohols—
Ethyl Alcohol From Wood Waste—Alcohol From Sulphite Waste Liquor—
Alcohol in the Dye Industry—Higher Alcohols

THE first regular meeting of the New York Section of the American Chemical Society for the 1919-20 season was held on Friday, Oct. 10. The evening was devoted to a symposium on alcohols, attention being focused upon the production and industrial uses of the more important alcohols.

The Future of Industrial Alcohols

MR. B. R. TUNISON discussed the factors which will influence the development of the industrial alcohol industry. New and important applications have been worked out, so that the outlook for the future is most promising.

Ethyl alcohol, the most important of the industrial alcohols, has been subject to so much taxation in the past that substitutes have been used in many cases where pure ethyl alcohol would have been more suitable. Thus manufacturers have been forced to use methyl alcohol for purposes to which ethyl alcohol was better adapted.

The production of other alcohols is a new industry in the United States. The war cut off the foreign supply of these alcohols, and their production, separation and purification constitute one of the rapidly growing industries of this country.

RAW MATERIALS

From the chemical and engineering viewpoints, almost any saccharine or starchy material may be used as a source of alcohol. Commercially, however, economic conditions operate to limit the available raw materials. Thus in Germany during the pre-war period agricultural conditions were such that potatoes were cheaper than grains. Beet-sugar molasses was used as a feeding material and as fertilizer, and there was not sufficient fruit waste to compete with potatoes. In France, grain, sugar beets and beet molasses are utilized. Switzerland's cheap water power has encouraged the development of a process starting with acetylene.

For many years maize was the chief source of alcohol in the United States. Waste sulphite liquor has been suggested, but there are very few mills which can supply sufficient waste liquor to keep a large plant in continuous operation. Grains are available only when not required as foodstuffs. Potatoes cannot be grown cheaply enough, and fruit waste is not available in sufficient quantity. The chief source at the present time, and the one which will apparently continue to occupy a leading position, is cane or black strap molasses from the sugar refineries of Cuba, Porto Rico and south-eastern United States.

Many suggestions have been offered concerning new raw materials for the manufacture of industrial alcohol. Among these may be mentioned artichokes, sorghum, fruits and fruit wastes, berries, the nipa palm of the Philippines, the sotol plant of Mexico, cassava, garbage waste, and ethylene recovered from gas and coal-tar distillation plants. It is evident that the main consider-

ation is an abundant, concentrated and constant source of raw material supply, since a plant producing only 100 gal. per day will require the equivalent of 200 gal. molasses or 2 tons of shelled corn every day. Molasses will undoubtedly be the chief source for a long time to come, since methods and apparatus are already well standardized for the use of this material and research work is being done upon the fermentation process with a view to improving yields.

USE IN TURPENTINE INDUSTRY

The turpentine gum is extracted with ethyl alcohol, which dissolves the gum turpentine but not the impurities. The solvent may be separated from the turpentine by fractional distillation. The rosin residue is of excellent quality and very light in color. The alcohol recovered contains turpentine which acts as a denaturant and may be sold as denatured alcohol or used for the extraction of a second batch of material.

ETHYLENE

When the vapors of alcohol are passed over heated kaolin or other suitable catalytic agents, ethylene is formed by catalytic dehydration

By means of this reaction, ethylene can be produced on a commercial scale at a price which enables it to compete with acetylene. Acetylene is not suitable for welding copper, as it produces blisters in the metal. Ethylene, however, may be successfully employed for this purpose. There is no danger of spontaneous explosion in compressing ethylene, so it may be compressed directly into cylinders without the use of the solvent acetone. Consequently a lighter container can be used, thus saving approximately one-half on the cost of the cylinder and on freight charges. Ethylene is a "one-man" gas, that is, a cylinder of a size sufficient for welding operations can be easily handled by one man. The gross weight, including the cylinder, per 100 cu.ft. of ethylene is only 40 lb., while the corresponding figure for acetylene is 90 lb. Ethylene is being sold in cylinders under the trade name of "calorine" at the same price as acetylene.

FUEL

The use of solidified alcohol as an easily transported, convenient source of heat is constantly increasing. It is unexcelled for use in localities where gas and electricity are not available.

The removal of many of the restrictions on the production, distribution and use of industrial alcohol will enable it to serve as a commercial fuel for internal combustion engines. It is claimed that the peak in the production of petroleum will be reached within the next two or three years. Even at the present time the demand for motor fuel exceeds the supply, so that there is urgent need for new sources of fuel. At the present time carburetors are not adapted to use alcohol alone,

but various mixtures have been tried giving better results than the present day gasoline. The most successful of these are mixtures of alcohol, gasoline, benzol and blending agents.

EFFECT OF INDUSTRIAL ALCOHOL ACT

It is hoped that the industrial alcohol act will relieve the manufacturer of industrial alcohol of much of the inconvenience hitherto experienced. The forms called for even at the present time are easy to execute and it should be possible to build up a large industry. The need for such an industry under present conditions is readily understood when we consider the question of where, without whiskey distilleries, shall we look for alcohol in case of war. The only answer possible is—the industrial alcohol industry.

The accompanying chart presents in graphic form some of the many uses of alcohol, and shows clearly the wide range of industries which require alcohol either as raw material or as a solvent.

Ethyl Alcohol From Wood Waste

DR. F. W. KRESSMANN discussed some of the conditions affecting the yield of alcohol produced by the hydration of cellulose in wood waste. The process has been systematically investigated by the Forest Products Laboratories. The optimum pressure was found to be 7½ atm. and the critical temperature 165 deg. C. Cooking time was found to be without influence on the total sugar, but the percentage of fermentable sugar increased with the time of cooking. The earlier work on this process was done with an amount of water equal to 400 per cent of the weight of the wood. It was found that 100 per cent of water gave the same or even a slightly better yield. The effect of varying the quantity of sulphuric acid used was determined in a series of tests using 125 per cent water, 7½ atm. pressure, and an instantaneous cook. The yield of alcohol increased rapidly up to 1.8 per cent H_2SO_4 .

Alcohol From Sulphite Waste Liquor

DR. RALPH H. MCKEE reviewed the recent progress in the utilization of sulphite liquor as a source of alcohol. The usual procedure is to heat sulphite liquor with lime sludge, filter off the precipitate of calcium sulphate and calcium sulphite and ferment the neutral liquor. The alcohol obtained contains up to 3 per cent of methyl alcohol and can be purified only with great difficulty. In 1918 this process, known as the "Ekstrom process," was in use at 15 plants in Norway and Sweden, 12 in Germany and Austria and at 1 plant in the United States. The total production for that year was about 6,000,000 gal. The explanation commonly given to account for the low yield is that a local excess of lime acts upon the sugar in the neutralization step, it being well known that glucose is readily destroyed by alkalis.

About two years ago, certain experimental work carried out in the Chemical Engineering Laboratories at Columbia University seemed to indicate that the inhibiting effect of sulphur dioxide and sulphites on the fermentation was due to the fact that they are reducing agents and thus use up the dissolved oxygen of the liquor. Bubbling air through the liquor tends to counteract this and waste liquor from which a portion of the free SO_2 has been removed ferments readily in the presence of yeast and a current of air.

The process is in operation at the plant of the Ham-mill Paper Co., Erie, Pa. Fermentations have lately

been made on 10,000 gal. charges and a small commercial size still capable of turning out 200 gal. 95 per cent alcohol per day has just been installed. The method of operation is as follows: The hot waste liquor (1400 to 2000 gal. per ton of pulp) is boiled in a preliminary treatment tank for about five hours, a current of air being introduced simultaneously. The SO_2 set free may be recovered, although this is not being done at this plant. The hot liquor is cooled counter-currently with water to about 29 deg. C., when it is run into the fermentation tank. Yeast and yeast foods such as ammonium sulphate and calcium acid phosphate are added. During fermentation a slow current of air is blown through the tank, furnishing oxygen for the yeast and keeping the yeast in suspension. After fermentation the alcohol is distilled in a continuous still to give high wines (50 per cent alcohol), which are rectified in discontinuous or batch stills.

The cost of production at this plant is from 18 to 30c. per wine gallon of 95 per cent alcohol, according to the glucose content of the waste liquor used. This cost includes charges for depreciation, interest, labor, steam, etc., but no charge for the sulphite liquor.

With a yield of 1 per cent of the waste liquor, there is obtained on an average 18 gal. of 95 per cent alcohol per ton of pulp. There are 95 mills in the United States producing an aggregate of 1,500,000 tons of sulphite pulp a year, so that the possible production is large.

Use of Alcohol in the Dye Industry

In speaking of the importance of alcohols in the dye industry, DR. LEONARD H. CRETCHER said that methyl and ethyl alcohols were extensively used as intermediates and as solvents.

The alcohols are spoken of as intermediates when used for alkylation. Dimethylaniline, prepared from methyl alcohol and aniline, is the most important alkylated amine. From dianisidine, representative of the class of alkylated phenols, benzopurpurine is prepared. Dyes themselves may also be alkylated. Ethyl esters of acetic and oxalic acids form another important class of products.

Higher Alcohols

DR. G. F. RICHMOND classified the higher alcohols used in the perfume industry briefly as follows:

1. *Methane Group.* Methyl alcohol is used as methyl salicylate and anthranilate. High-grade ethyl alcohol is essential to the manufacture of perfumes. Iso-butyl alcohol is indispensable for the preparation of musk odors. Amyl salicylate is the basis of perfumes of the orchid type. Octyl alcohols give that sweet smell "which distinguishes a rose from a rose perfume." The alcohols with twelve carbon atoms have a delicate odor suggestive of the lily.

2. *Geraniol Group.* Geraniol is found in otto of rose. Other members of this group are nerol, linalool, citronellol and rhodinol.

3. *Terpene Group.* Terpineol is the most important member of this group. It is used in lily of the valley and lilac perfumes and in soap scents.

4. *Aromatic Alcohol Group.* Benzyl alcohol, phenyl ethyl alcohol and cinnamyl alcohol are representative of this group.

The complexity of the problem is further increased by the fact that, of the 36 distinct alcohols used, many may also be used as aldehydes and ketones or combined with any one of 25 acids as esters.

CHART SHOWING SOME OF THE MANY USES OF ALCOHOL

Application of the Interferometer to Gas Analysis

Principle of the Interferometric Method as Applied to Gas Mixture Analysis—Effect of Variations in Gas Composition and Experimental Conditions—Typical Examples of Interferometric Determinations on Carbon Dioxide-Air, Flue Gases, Helium-Nitrogen-Methane Mixtures

BY JUNIUS DAVID EDWARDS

IT IS only within recent years that extended practical application of physical methods to chemical analysis has been made. This has been especially true in the case of gas analysis. Progress in developing new and improved methods for gas analysis was slow so long as differentiation by chemical characteristics alone was employed. However, there are quite a number of physical characteristics of gases, such as refractivity, thermal conductivity, heat of combustion, density, viscosity, etc., which offer almost unlimited possibilities for the development of gas analysis apparatus for various purposes.

One of the most useful of the physical methods which have been developed is that of gas interferometry. Rayleigh¹ first described the essential features of this method. Later Haber and Lowe² developed what is known as the Rayleigh-Zeiss gas interferometer, which marks the first practical application of the method. Interferometers of the Rayleigh type are now manufactured by Hilger of London. Although widely used abroad, the number in use in this country has been rather limited—less than their utility would warrant.

The author³ has described a new method of calibrating the gas interferometer, which greatly simplifies and extends its use. The present paper will discuss the simple relations which exist between the properties of the gases and the indications of the instrument, and give examples illustrative of its use.

PRINCIPLE OF METHOD

The gas interferometer is essentially a differential refractometer; it measures the difference in refractivity of two samples of gas. The gases are contained in two long (100 cm. in one instrument) narrow gas chambers, the ends of which are closed by plane parallel glass plates. White light from an illuminated slit passes through both chambers, after which the two beams combine to produce interference fringes which are observed through an eye piece. If the composition of the gas in the two tubes is different, the optical paths through the tubes are different and the interference fringes are displaced from their normal position. The optical path of one of the beams can be adjusted to equality with the other by tilting a glass compensator plate, which is placed in the path of the beam. The angle through which the compensator plate must be turned to bring the two optical paths to equality, as shown by the position of the interference fringes, is a measure of the difference between the refractive indices of the two gases. This adjustment is made by means of a micrometer screw acting on a lever arm attached to the compensator plate. A second set of fringes, produced by two beams of light which pass over the

gas tubes and which are fixed in position because the two beams always have equal optical paths, are used as a reference point in much the same way as the cross hair in a telescope. The reader is referred to the more complete descriptions in the literature for further details of the apparatus.

THEORETICAL RELATIONS

The refractivity (R) of a gas is equal to the refractive index minus 1.

$$R = n - 1 \quad (1)$$

It has been shown that the refractivity of a gas is proportional to its density, or

$$\frac{R}{d} = \text{constant} \quad (2)$$

This relation holds with considerable exactness for gases at ordinary temperatures and within a pressure range of a few atmospheres. From equation 2 the refractivity of a gas can be calculated for different temperatures and pressures by the application of the gas laws, since the density of a gas is proportional to its pressure. When the deviations of the gas from the simple gas laws are important, they can be taken into account, as will be shown later.

The refractivity of a gas mixture can be calculated from the refractivity of the components and the composition of the mixture. In a binary mixture, composed of gases having refractivities R_1 and R_2 , the refractivity, R , for any proportion of the two gases is given by equation 3, in which a and $(100 - a)$ are the proportions in which they are present.

$$R = \frac{R_1 a + R_2 (100 - a)}{100} \quad (3)$$

The available evidence shows that this equation holds with considerable accuracy. For example, the refractivity of air, calculated in this manner from the values given in Table I for the refractivities of its constituents, is 2915×10^{-7} as compared with the observed value 2917×10^{-7} .

The reading of the interferometer is a measure of the difference in refractivity of the gases in the two chambers. This difference in refractivity can be easily calculated from the preceding relations. If R_1 is the refractivity of one gas at 0 deg. C. and 760 mm., and R_2 is the refractivity of the second gas or standard of comparison under the same conditions, then the difference of refractivity of the two gases at any pressure p and absolute temperature T is as follows:

$$(R_1 - R_2)_{T,p} = \frac{273}{T} \cdot \frac{p}{760} \cdot (R_1 - R_2) \quad (4)$$

The interferometer reading is determinate only for binary mixtures or their equivalent; mixtures of constant composition, such as air, for example, may be regarded as a single component. It is the usual practice where convenient to use one of the components of the

¹Rayleigh, *Proc. Roy. Soc.*, 59, p. 201, 1896.

²Haber and Lowe, *Zangw. Chem.*, 23, p. 1393; 1910.

³Edwards, *J. Am. Chem. Soc.*, 39, p. 2382; 1917.

gas mixture as the standard gas. In this case the difference in the refractivity of the mixture and one of its components is measured. If R_1 and R_2 are the refractivities of the two gases, then the change in the refractivity of the mixture (ΔR) for a change of a per cent of one of its components is as follows:

$$\Delta R = \frac{273}{T} \frac{p}{760} \frac{a}{100} (R_1 - R_2) \quad (5)$$

Equation 5 also represents the change in the difference between the refractivity of the mixture and any standard gas for the change in composition stated. The symbol ΔR will be used to represent the change in refractivity of the mixture for a given change in composition, and the symbol Δr will be used to represent the difference in refractivity between the gases in the two chambers. Under certain conditions ΔR and Δr are numerically equal, but a distinction is made to simplify the discussion of certain problems.

CALIBRATION OF INTERFEROMETER

Each scale division of the interferometer corresponds to a definite value of Δr which is a characteristic of the instrument. If now the interferometer could be calibrated in terms of Δr so that the refractivity difference for any scale reading was known, then its calibration for any gas could be calculated if the refractive index of that gas is known.

The author has described a method of calibration of the interferometer, based on this principle,* which is extremely simple and easy to carry out. To determine the scale reading corresponding to a given difference in refractivity, both chambers of the interferometer are filled with dry air, free from carbon dioxide, and at a definite temperature and pressure. The pressure and hence the refractivity of the gas in one chamber is then varied progressively and the scale reading corresponding to each pressure noted. The pressures in the two chambers are p_1 and p_2 , and the temperature T remains constant. The refractive index (n_D) of air, free from carbon dioxide, at 0 deg. and 760 mm. pressure as determined by Meggers and Peters† is 1.0002917.

It follows from equations 1 and 2 that ΔR , or the difference in refractivity corresponding to each scale reading (observed reading minus "zero" reading), can be calculated as follows:

$$\Delta R = \frac{273 \times 0.0002917 (p_1 - p_2)}{760 T} \quad (6)$$

From the curve of refractivity differences determined in the above manner, the scale reading corresponding to the refractivity difference calculated from equation 5 can be ascertained and a curve constructed giving the scale reading for any percentage of the gas for which the calibration is desired.

REFRACTIVITIES OF THE GASES

It is apparent that the accuracy of this method of calibration is limited among other things by the accuracy with which the refractive indices have been determined. The refractive index of air is known from the work of Meggers and Peters to within a part in a thousand. The refractive indices of most of the other common gases are known with sufficient accuracy to be used for calibrating the interferometer. The tables of refractive indices, such as that given by Landolt-Börnstein, are somewhat confusing because of the

differences between the observations of different experimenters. Therefore, in arriving at the most probable value for any of these constants it is necessary to make a critical examination of the details of the measurements, whenever possible. In Table I are given the refractive indices of a number of the common gases. The values are all for a wave length of 589×10^{-6} mm. (sodium or D line), since the data are most complete for this wave length and it represents fairly well the average wave length of the light used in the interferometer. The values given in this table have been found by taking the average of the most reliable observations and represent the author's judgment of the best values to use.

It will be noted that the refractivity values in this table are for gas at 0 deg. C. and under a pressure of 760 mm. of mercury.

TABLE I—REFRACTIVITY OF CERTAIN GASES

Gas	Formula	Refractivity $\times 10^{-7}$	"Ideal" * Refractivity $\times 10^{-7}$

REFRACTIVITY AT LOW PARTIAL PRESSURES

For small changes in pressures or temperature the density and therefore the refractivity can be calculated with sufficient accuracy by means of the gas laws as indicated in equations 4, 5 and following. If, as is usually the case, a small percentage of a gas is being measured, its partial pressure will be small. If the deviation of the gas from Boyle's law is significant, the refractivity of the gas at this low partial pressure may differ from the value calculated from the ratio of the pressures. The correction necessitated by this fact will now be discussed.

The refractivity of a gas is the sum of the refractivities of its constituents. If the molecules in a mixture of gases could be sorted out and the refractivities of each kind totaled, the refractivity of the mixture could probably be ascertained with high precision. Because this is not possible, we have used in the discussion a larger unit of measurement, which is the number of molecules contained in a unit volume of the gas at a definite temperature and pressure. It is therefore necessary to know how the number of molecules in a unit volume varies with changes in temperature and pressure. This variation is given with close approximation for many gases by the simple gas laws. In order to calculate the number of molecules of each kind in a mixture of gases, we have further made use of what is known as Dalton's law.

Dalton's law, as commonly expressed, states that the pressure of a mixture of gases is equal to the sum of

* Bull. Bureau of Standards 14, p. 473; 1917. J. Am. Chem. Soc., 39, p. 2382; 1917.

† Bull. Bureau of Standards, 14, p. 697; 1918.

the pressures which each gas would exhibit if it occupied the total volume alone. In applying this law, we have assumed according to Boyle's and Avogadro's laws that the number of molecules in a unit volume is proportional to the pressure. If Dalton's law were strictly true, then the exact refractivity at any partial pressure could be calculated by using the observed expansion coefficients or, what is the same thing, correcting the values calculated by Boyle's law for the deviations from it. Dalton's law, just as Boyle's law, is, however, strictly correct only for the limiting case of perfect gases. Consequently, a gas at a pressure of 1 mm. does not necessarily have the same refractivity that it would if it had a partial pressure of 1 mm. in a mixture of gases. The reason for this is that in a mixture of gases the attractive forces between different species of molecules come into play and modify the volume relations. The more nearly two gases resemble each other in their physical properties (critical temperature and pressure, density, etc.) the less effect deviations of the gases from Boyle's law have upon their partial pressures. As an illustration, it is obvious that a partial pressure of 1 per cent of carbon dioxide in carbon dioxide, if we can speak of such a thing, shows no deviation from Boyle's law because it has already the same physical properties as the gas with which it is mixed, namely, carbon dioxide. However, a partial pressure of 1 per cent of carbon dioxide in air will show a certain deviation from Boyle's law.

The work of Berthelot,⁶ Fuchs⁷ and others have shown that the mixing of two gases originally at the same temperature and pressure is accompanied by a small increase in pressure or volume. The change in volume is a minimum when the gases which mix are most nearly alike in their physical properties. It appears, therefore, that in most cases the deviations from Boyle's law at low pressures should be taken account of in calculating the refractivities of mixtures, at least until more data are available on this point. In the case of mixtures of two gases, such as oxygen and nitrogen, or carbon dioxide and nitrous oxide, which are very similar in their physical properties, the use of the observed refractivities will give the best results. In the case of dissimilar gases, the "refractivities" at low partial pressures should be corrected for the deviations from Boyle's law.

The discussion of this point has perhaps taken more space than its importance would warrant, but because these facts are usually overlooked in similar cases, it has been thought desirable to call attention to them.

The deviation of a gas from Boyle's law can be calculated with sufficient precision from Berthelot's equation of state for gases and vapors. Jones and Partington⁸ have calculated by means of Berthelot's equation what they call the "ideal refractivity" of the gas. The "ideal refractivity" is, in effect, the refractivity at 0 deg. C. and 760 mm. calculated by means of Boyle's law from the refractivity at very low pressures. Consequently the refractivity of any gas at a low partial pressure can be more precisely calculated from this value by application of Boyle's law than from the observed value at 760 mm. The values for the "ideal refractivity" given in Table I should be used where the difference in refractivity caused by a small percentage of the gas is desired, subject to the conditions outlined

NOTES ON THE OPERATION OF THE INTERFEROMETER

In the use of the interferometer it will be noted that the readings are a function of the temperature and pressure. For the greatest convenience calibration curves should be drawn for different temperature and pressure intervals so that the correct reading can be obtained by interpolation. In the usual method of using the instrument and of calibrating with analyzed gas mixtures it is apparently customary to neglect the effect of temperature and pressure. It can be seen from the equations that if the readings are made at a temperature only 3 deg. C. higher or lower than the temperature at which the instrument was calibrated, they will be in error by 1 per cent. The errors from this source, if neglected, may easily be greater than any of the errors of calibration.

Another error in the use of interferometers which employ a glass compensator plate comes from the shift of the central white or achromatic fringe. This is due to differences in the relative dispersion of the gases and air and glass. L. H. Adams⁹ has analyzed this phenomenon for the Zeiss interferometer and developed equations by which the shift may be estimated. What takes place is that, as the concentration of a gas is changed, the edges of the central achromatic fringe gradually become colored and the original central fringe no longer is the most nearly achromatic fringe, provided the concentration change has been carried far enough. The result is in effect a shifting of the reference point.

The number of scale divisions through which the compensator must be turned to shift the achromatic fringe a distance of one band varies, of course, with every gas. The interval can be determined experimentally by increasing the concentration of the gas in one chamber gradually and constantly, meanwhile keeping the original central fringe in line with the reference fringe. (See section on principle of method.) The concentration can be increased gradually by allowing the gas to enter the chamber through a small needle valve and slowly dilute the mixture. If at any scale reading the original central fringe is still the most nearly achromatic, no error can result from that cause, because it would still be aligned with the reference fringe to obtain the scale reading. The scale reading when the achromatic fringe has shifted the width of one band should be noted.

A portable interferometer was tested in this way with carbon dioxide, which has a considerably higher dispersion than hydrogen, nitrogen, oxygen, etc. There was no uncertainty as to which was the original central fringe until concentrations as high as 60 to 80 per cent of carbon dioxide were reached. This is well beyond the range of instruments with 100 cm. gas tubes. Because of the low dispersion of most gases no difficulty will be usually met with from this source when low concentrations, say 20 per cent or less, are being used. Furthermore, when there is any doubt as to whether or not a shift has occurred, it can be determined experimentally in the manner indicated.

ILLUSTRATIVE CASES

To illustrate the use of the equations and show how the sensitivity of the interferometer varies under different conditions of use and with different gases, a number of typical cases will be discussed. The ease and simplicity with which variations in ΔR and its

equivalent, the scale reading, can be calculated for different conditions will be demonstrated. Although the instrument can in most cases be calibrated with analyzed mixtures, the method here described is usually as accurate, if not more so.

One of the commonest uses of the interferometer is for the determination of carbon dioxide in mixtures of carbon dioxide and air. There are three typical cases which may be considered. First, a mixture of carbon dioxide and normal air is compared with normal air as a standard. Second, a mixture of carbon dioxide and "air" in which there is a deficiency of oxygen is compared with normal air; such mixtures may occur in mines, for example. Third, a mixture of carbon dioxide and "air" in which there is a deficiency of oxygen is compared with the residue remaining after the carbon dioxide has been removed by absorption.

First Case. The difference in refractivity between normal air and air containing the same proportion of nitrogen and oxygen, together with 1 per cent of carbon dioxide, at 20 deg. C. and 760 mm. pressure can be calculated from equation 5.

$$\Delta r = \frac{273}{293} R = \frac{1}{100} (4467 - 2917) = 14.44$$

Second Case. If 1 per cent of oxygen in the above mixture is replaced by 1 per cent of nitrogen, then R_2 , the refractivity of the "air," is increased by 1 per cent of the difference between the refractivities of nitrogen and oxygen, and ΔR is apparently increased by the same amount, or

$$\frac{1}{100} \cdot \frac{273}{293} (2972 - 2706) = 2.48$$

The refractivity of the standard gas (air) remains constant. Accordingly the carbon dioxide, as indicated by the calibration in the first case, will be $\frac{2.48}{14.44}$ of the

1 per cent, or 0.172 per cent too high for each change of 1 per cent of oxygen. For example, if the interferometer indicated 3.34 per cent carbon dioxide and the mixture contained 18.25 per cent oxygen, there would be a deficiency of 2 per cent $[(100 - 3.34) \times 0.2094 - 18.25]$ in the air, and the corrected percentage of carbon dioxide would be $3.34 - (2 \times 0.172) = 3$ per cent. This calculation neglects the fact that the value for the percentage of air in the gas $(100 - 3.34)$ is only a first approximation; a closer approximation to the correct value is obtained by using the corrected figures for carbon dioxide, which give $100 - 3.0 = 97$ per cent air. Using this value, the deficiency in oxygen is found to be 2.06 per cent instead of 2 per cent and the corrected percentage of carbon dioxide equals 2.99 per cent.

Burrell and Seibert¹⁰ determined the effect of a deficiency in oxygen experimentally and made six observations (0.135, 0.103, 0.128, 0.155, 0.162, and 0.160) from which they concluded that each 1 per cent lowering of the oxygen content increased the apparent amount of carbon dioxide by 0.15 per cent. In calculating their values they subtracted the percentage of oxygen in the mixture from the percentage of oxygen in normal air (they use 20.93 per cent). It is obvious, however, that the percentage of oxygen in the mixture varies with the amount of carbon dioxide present and the final value they calculate is, therefore, not a constant as assumed. Take their first observation: The mixture contained 0.50 per cent carbon dioxide and 20.19 per

cent oxygen. The air present in the mixture is then 99.5 per cent, and if it were normal air the percentage of oxygen in the mixture would be $99.5 \times 0.2093 = 20.82$ and the deficiency of oxygen, expressed as a percentage of the original mixture is $20.82 - 20.19 = 0.63$ per cent. The difference between the carbon dioxide indicated by the interferometer and by chemical analysis was 0.10 per cent. The error in the observed percentage of carbon dioxide for each per cent deficiency of oxygen is then $\frac{0.10}{0.63} = 0.159$ per cent, instead

of 0.135 as calculated by their method. When calculated on this basis, the average of Burrell and Seibert's six experiments is 0.166 per cent, which is in fair agreement with the value 0.172 calculated in the preceding paragraph.

Burrell and Seibert¹⁰ also concluded from six observations (0.174, 0.179, 0.138, 0.150, 0.167, and 0.179) that this figure was, for methane, 0.16 per cent for each per cent lowering of oxygen when normal air was used as standard. Their values recalculated on the correct basis give an average of 0.182 per cent, which is in fair agreement with the theoretical value of 0.179.

Third Case. The analysis of the third case, where the carbon dioxide is removed from the mixture before passing it into the second chamber to serve as the standard gas, is of especial interest because this method greatly reduces the errors due to other variations in the composition of the mixture and extends the use of the interferometer to other than strictly binary mixtures.

The effect of any variation in composition upon the difference in refractivity of the gases in the two chambers can be easily calculated. In the case at hand let R_1 be the refractivity of the constituent for which the calibration is sought and R_2 be the refractivity of the standard gas which remains after removal of the first gas from the mixture. Also let R_3 be the refractivity of the gas such as oxygen, nitrogen, etc., which dilutes the original mixture and also the standard gas. Then let a be the percentage of R_1 and b the percentage of R_3 which is present.

The difference in refractivity between the two chambers when a per cent of the first gas is in one chamber is given by equation 6.

$$\Delta r = \frac{a}{100} (R_1 - R_2) \quad (6)$$

If now b per cent of the gas having the refractivity R_3 is present the difference in refractivity between the two chambers is as follows:

$$\Delta r_1 = \left[R_1 \frac{a}{100} + R_2 \frac{(100 - a - b)}{100} - R_3 \frac{b}{100} \right] - \left[R_2 \frac{(100 - a - b)}{100 - a} + R_3 \frac{b}{100 - a} \right] \quad (7)$$

In this equation the quantities in the two brackets are the refractivities of the gases in the two chambers. It should be noted that the change of b per cent of the third gas in the mixture corresponds to a change of $\frac{b}{100 - a}$ in the residue after a per cent of the first gas has been removed. Equation 7 simplifies to

$$r_1 = \frac{R_1 a}{100} - \frac{0}{100^2 - 100a} \left[R_2 (100 - a - b) - R_3 b \right] \quad (8)$$

Subtracting equation 8 from 6 to determine the differ-

¹⁰Bureau of Mines Bull. No. 42, p. 73; 1913.

¹¹Bureau of Mines Bull. No. 42, p. 73; 1913.

ence in Δr , with and without the third gas, we have

$$\Delta r - \Delta r_1 = \frac{ab}{100^2 - 100a} (R_3 - R_2) \quad (9)$$

Equation 9 can be written by inspection when the relations involved are understood; however, it is developed in the above manner in order to make each step clear.

The effect on the indicated percentage of carbon dioxide in air, when the composition of the air varies, can now be calculated. If a , the percentage of carbon dioxide, and b , the change in percentage of oxygen from normal (20.94 per cent), are both 1, then at 20 deg. C.

$$\Delta r - \Delta r_1 = \frac{273}{293} \cdot (2706 - 2972) \cdot \frac{1}{9300} = -0.025.$$

ΔR for 1 per cent of carbon dioxide in air under the conditions of the first or normal case is 14.44; the observed reading under the conditions of the third case

is accordingly $\frac{-0.025}{14.44}$ of the 1 per cent, or 0.0017 per cent, too low. When normal air was used as the standard gas each decrease of 1 per cent of oxygen raised the apparent amount of carbon dioxide by 0.172 per cent.

In the cases just cited there was a deficiency of oxygen. The case in which there is an excess of oxygen in the "air" is also met with in practice and is treated in a similar manner. This condition occurs in the analysis of gas from a balloon or airship having an envelope of rubberized fabric. Because of the higher permeability of rubber to oxygen than to nitrogen the "air" penetrating rubber may contain as high as 41 to 42 per cent oxygen.¹¹ This fact should be taken account of in all analyses of gases from balloon envelopes.

Choice of Standard Gas. It may be remarked in passing that the character of the standard gas has no relation to the sensitivity of the interferometer. It merely provides a standard constant refractivity from which differences may be measured. A change of 1 per cent of carbon dioxide in air produces the same difference in scale reading (providing the scale is linear) whether air or carbon dioxide or any other gas is the standard. It makes a great practical difference, however, in convenience and accuracy as to what gas is used as the standard. Take the case of carbon dioxide in air. If 1 per cent of carbon dioxide in air is compared with air as a comparison gas, then Δr , the difference is refractivity between two chambers,

is equal to $\frac{1}{100} \times 1444$ at 20 deg. C. and 760 mm. pressure. If carbon dioxide is used as a comparison gas the difference in refractivity between the two chambers is equal to $\frac{99}{100} \times 1444$. In the first case, a change of 1 per cent in temperature or pressure makes a difference in Δr (see equation 6) corresponding to 0.01 per cent carbon dioxide $\left(\frac{0.14}{14.44}\right)$. In the second case such a change in temperature or pressure makes a difference in Δr corresponding to 0.99 per cent carbon dioxide $\left(\frac{0.01 \times 0.99 \times 14.44}{14.44}\right)$, which is almost as much as the quantity being determined (1.00 per cent).

It is thus apparent that the greatest freedom from error due to changes in temperature and pressure is

secured when the difference in refractivity between the mixture and the standard gas is a minimum. This condition is usually met when the major constituent of the mixture is used as the standard gas; the zero reading of the interferometer then corresponds to a zero difference in optical path between the two tubes.

Analysis of Flue Gas. The interferometer has been suggested and used for the analysis of flue gas. The situation in this case is rather complex because of the number of gases which may be present in the mixture. Usually the percentage of carbon dioxide in a flue gas is determined because it is an index of the proper firing conditions. The flue gas can be considered to be a mixture of carbon dioxide and nitrogen with varying amounts of oxygen, carbon monoxide, hydrogen, methane, and water vapor, depending upon the fuel used, the completeness of combustion, etc. It is interesting to analyze the conditions and show what the error would be with any combination of gases.

The best method of operation, of course, is to absorb the carbon dioxide after passing the gas through one chamber and use the residue as a standard of comparison. Take the case of a furnace gas of the composition shown in Table II. In this example carbon dioxide is the gas sought and the residue after the absorption of the carbon dioxide is assumed to be nitrogen (considering the argon present as nitrogen) with the other gases as diluents. In Table II are tabulated the corrections to ΔR calculated according to equation 9.

TABLE II—CORRECTIONS TO INDICATED PERCENTAGE OF CARBON DIOXIDE FOR A CERTAIN FURNACE GAS

Constituent	Per Cent Present	$\Delta R \times 10^{-7}$	$\left(\frac{ab}{100^2 - 100a}\right) \cdot \Delta R \times 10^{-1}$
CO ₂	13.0	CO ₂ - N ₂ = +1498	—
O ₂	2.0	O ₂ - N ₂ = -266	-0.83
CO	4.6	CO - N ₂ = +373	+2.69
CH ₄	0.2	CH ₄ - N ₂ = +1436	+0.45
H ₂	1.4	H ₂ - N ₂ = -1585	-3.46
N ₂	78.3		
Net correction			-1.15

The corrections in the last column are calculated in the manner indicated. The value for the 2 per cent of oxygen, for example, is $\left(\frac{2 \times 13.5}{10,000 - 1,350}\right) \times (-266) = -0.83$. The error in the reading for 13.5 per cent carbon dioxide is $-\frac{1.15}{14.98 \times 13.5} = -0.0057$, or the percentage of carbon dioxide indicated by the interferometer will be $13.5 - (0.0057 \times 13.5) = 13.42$ per cent CO₂. The amount of this correction is entirely negligible in any flue gas analysis. Mohr¹² has analyzed a number of flue gases and found that the percentage of carbon dioxide as determined with the interferometer agreed within the limits of the instrument (0.1 per cent CO₂) with the values found by the usual method of gas analysis by absorption. The errors of the interferometer were of the order indicated by the theory discussed above.

The carbon monoxide and methane in the furnace gas could also be determined by first removing all the carbon dioxide and then oxidizing the carbon monoxide and methane with hot copper oxide. The carbon dioxide formed in the gas mixture could then be determined in the manner just outlined and this percentage would be equal to the sum of the percentage of carbon monoxide and methane originally present.

Kreisinger, Augustine and Ovitz¹³ have found that

¹¹See article by Edwards and Ledig on "The Significance of Oxygen in Balloons," *Aviation Acron. Eng.* 6, p. 325; 1913.

¹²Mohr, *Z. angew. Chem.*, 25, p. 1313, 1912.

¹³Bureau of Mines Bull. 135, p. 107; 1917.

the combustible gases in furnace gas, other than carbon monoxide, consist mainly of hydrogen; methane and other hydrocarbons occur only in traces. Furthermore, the carbon monoxide constitutes about 80 per cent of the total combustible gases. These observations are of interest in connection with the subject of flue gas analysis.

Determination of Helium in Mixtures. The interferometer was found useful in the analysis of a sample of helium produced by the fractional liquefaction of natural gas; the details of the analysis are of interest because they illustrate the use of the methods already discussed. From the method of manufacture, the gas was known to consist of helium and nitrogen, with smaller amounts of methane. Tests showed the absence of oxygen in the mixture. Because of the presence of three constituents, the readings of the interferometer alone are not determinate. Accordingly the methane (other hydrocarbons assumed to be absent) was determined in a separate sample by combustion with oxygen over a heated platinum wire; the amount found was 0.2 per cent. The interferometer gave a reading of 1577 scale divisions when the mixture was compared with air. The calibration of the interferometer showed this to be equivalent to a Δr of 2421×10^{-7} at 0 deg. C. and 760 mm. pressure. The refractivity of the mixture is then equal to $2917 - 2421 = 496 \times 10^{-7}$. If x equals the percentage of helium ($R = 342 \times 10^{-7}$) present, then the refractivity of the mixture is also given by the following relation (see equation 3).

$$x(342) + (1.00 - x - 0.002)(2972) + 0.002(4415) = 496, \text{ which gives } x = 0.943$$

The complete analysis is then as follows:

	Per Cent
Helium.....	94.3
Nitrogen.....	5.2
Methane.....	0.2

The analysis made in this way was checked by using the density of the mixture and its constituents in place of the refractivity. This latter method indicated the presence of 94.6 per cent helium in the mixture. The difference is only 3 parts in 1000, which is quite a satisfactory agreement. It is much simpler and quicker, however, to determine the refractivity with the interferometer than to determine the density with the necessary accuracy.

Another sample of helium analyzed in the same manner with the interferometer showed the following composition:

	Per Cent
Helium.....	53.6
Nitrogen.....	34.5
Methane.....	11.9
	100.0

The percentages of helium and nitrogen were also calculated from the density of the mixture and found to be 53.4 and 34.7, which is also a very satisfactory agreement considering the nature of the problem.

SENSITIVITY OF INTERFEROMETER

The sensitivity of the interferometer depends on the length of the gas chambers and certain other constants of the instrument. The Zeiss portable interferometer with 10 cm. tubes indicates about 0.1 per cent carbon dioxide in air for each small scale division. The laboratory type with 100 cm. chambers indicates about 0.01 per cent carbon dioxide. The relative sensitivity of the instrument for different gases is shown in Table III. It is assumed that each scale division indicates

0.01 per cent carbon dioxide. The percentage of other gases in certain mixtures, which is indicated by each scale division, is shown in the last column.

TABLE III—RELATIVE SENSITIVITY OF INTERFEROMETER FOR DIFFERENT GASES

Constituent to Be Determined	Composition of Mixture	$\Delta R \times 10^7$ for 1 per Cent of Gas at 0 Deg. C. 760 mm.	One Scale Division Indicates per Cent
Carbon dioxide	CO ₂ - Air	15.50	0.0100
Methane	CH ₄ - Air	14.91	0.0104
Hydrogen	H ₂ - Air	15.29	0.0101
Oxygen	O ₂ - N ₂	13.18	0.0118
Oxygen	O ₂ - N ₂	2.66	0.0583
Nitrogen	N ₂ - N ₂	2.66	0.0583
Helium	He - N ₂	26.30	0.0059
Acetylene	C ₂ H ₂ - Air	30.54	0.0058

Many other interesting cases could be discussed; the present examples, however, are typical of those met with in practice and illustrate the use of the equations and the method of determining the suitability of the interferometer for any specific purpose.

SUMMARY

The principle of the gas interferometer and its method of use in gas analysis are discussed in connection with the calibration of the instrument. The effect produced upon the observations by variations in gas composition and experimental conditions is analyzed and equations developed by which the magnitude of such changes can be estimated. Typical cases in which the interferometer may be employed, such as for the analysis of mixtures containing helium, analysis of flue gas, etc., are given, together with points on sources of error, details of operation and the relative sensitivity of the interferometer for different gases.

House Passes Magnesite Tariff Bill

In passing the magnesite tariff bill, the House has added another to the number of tariff bills pending before the Senate Committee on Finance. The Senate committee has postponed indefinitely the consideration of these bills, and has expressed itself as being unfavorable to piecemeal tariff revision.

The duties imposed in the House bill are 1c. per lb. on magnesite ore, 3c. on calcined, dead-burned and grain magnesite and 3c. per lb. and 10 per cent ad valorem on magnesite brick. The duties imposed are claimed to be so high as to prohibit imports of magnesite, but the Republicans scored a strong point in showing that the increased rate would add only 3 1/2c. a ton to the price of the finished steel. The bill was passed by vote of 154 to 112.

Silicate Rock Analysis

Analytical chemists will be interested in the fact that a new and revised edition of Dr. W. F. Hillebrand's "Analysis of Silicate and Carbonate Rocks" is in press. Like its predecessors, it will be issued as a bulletin of the United States Geological Survey. Its number will be 700, superseding bulletin 422.

Alpha-Naphthol and Xylidine Mixture as Flotation Agent

In the issue of Oct. 1, Vol. 21, page 418, alpha-naphthylamine should be substituted for alpha-naphthol, which is erroneously stated as a component of the X-cake-xylidine-flotation reagent.

Atomic Structure of Metals in Solid Solution

Experimental Data on Specific Resistance, General Considerations as to Hardness, and the Electronic Theory, All Indicate That Solid Solutions Contain a Large Amount of Supercooled Metal With Liquid or Amorphous Structure

By A. L. FEILD

THE industrial importance of solid solution alloys is too great to be comprehended fully unless consideration is given to the fact that hardened steel and the majority of the alloy steels, of which tungsten, nickel and manganese steels are familiar examples, as well as the common electrical resistance alloys, such as nichrome, manganin and constantan, all belong to this same general class. Any theory, therefore, which offers a reasonable explanation of the mechanism by which the physical properties of these alloys are caused to depart to so great an extent from those of their constituents would appear to be worthy of consideration.

SOLID SOLUTIONS HAVE HIGH SPECIFIC RESISTANCE

The relatively high resistance of alloys which consist of two or more metals in solid solution has not heretofore received a satisfactory explanation. When, for instance, increasing amounts of gold are added to silver to form a series of solid solution alloys, the curve expressing the specific resistance as a function of the composition rises sharply from the value corresponding to pure silver to a maximum and drops sharply to the value corresponding to pure gold. (See Fig. 1, curve A.) On the other hand, for two metals, such as lead and tin, which form a strictly eutectiferous series of alloys, the specific resistance-composition curve is very nearly a straight line.

THE WIEDERMAN-FRANZ-LORENZ LAW AND THE ELECTRON THEORY OF METALS

It is significant that the electron theory of metallic conduction gives no explanation of the peculiar properties of solid solutions. Nor has the electron theory attempted to do so, other than to remark that when solid solution occurs in an alloy neither the electric nor the thermo-electric properties of the alloy are additive functions of the corresponding properties of the constituents; but that, on the contrary, the solid solution behaves in no way similarly to a pure metal, as, for instance, with regard to its failure to comply with the Wiedemann-Franz-Lorenz equation. This equation holds with very considerable accuracy for practically all pure metals, and states, in effect, that the ratio of the thermal to the electrical conductivity multiplied by the absolute temperature is a constant for all metals.

Unfortunately, this law holds only for a narrow range of temperature in the neighborhood of ordinary room temperature, and at both elevated and very low temperatures it has been found experimentally not in accord with the facts in the case. With the electron theory in its present state of development, it is not possible to say more, in the case of the anomalous behavior of solid solutions, than that in such a case the volume concentration of free electrons is greatly diminished, or the number and distribution of the attracting centers are altered, or a change occurs in the variation of

the attracting force with distance, or else that the characteristic behavior is the resultant of some combination of these factors and their temperature functions.

Obviously, such an explanation does not elucidate the problem to any noticeable degree. We do know, however, that in general the effect of adding to a pure metal some other metal with which it forms a solid solution is to decrease the electrical conductivity relatively to a greater extent than the thermal conductivity. In the light of what follows it is seen that this phenomenon is due to the fact that with increasing temperature the electrical resistance of a pure metal decreases more rapidly than does the thermal conductivity.

It is true that the theory has predicted correctly, in the case of a series of solid solution alloys, that the characteristic shape of the resistance-composition curve would be reflected in the curve of thermo-electromotive force versus composition, since both conductivity and thermal e.m.f. are dependent upon the electron distribution within the material.

On the other hand, the same reasoning would lead one to look for a sharp break or discontinuity in the thermo-electric power of a metal on passing from the solid to the liquid state, corresponding to the observed phenomenon in the case of the property of electrical resistance. So far, however, no such break in the thermo-electric properties at the melting point has been observed.¹ Lord Rayleigh's² hypothesis as to the existence in alloys of a

FIG. 1. COMPOSITION CURVE OF Ag-Au ALLOYS, FROM MEASUREMENTS BY MATTHIESSEN

A—Specific resistance-composition curve of Ag-Au alloys. B—Hardness-composition curve of Ag-Au alloys.

ence in alloys of a false resistance arising from a Peltier e.m.f. at the junctions between the constituents of the alloy cannot be applied to solid solution alloys, where, as is known, the intermingling of these constituents is actually molecular in its nature, and because, in the case of eutectiferous alloys where it should certainly

¹See P. Cermak and H. Schmidt, *Ann. Physik*, vol. 36, pp. 575-88 (1911).

²*Nature*, vol. 54, p. 154 (1896).

apply, the observed deviations from linearity in the resistance-composition curve are of a very small magnitude and not entirely inexplicable on different grounds.

DISCONTINUITY IN ELECTRICAL PROPERTIES AT MELTING POINT

In the case of the common metals the specific electrical resistance is roughly proportional to the absolute temperature. This law holds with fair accuracy in the temperature range 0 deg. to 100 deg. C., but the observed deviations become more prominent as the temperature increases. In metals, such as iron, which undergo allotrophic changes, there occur at the transformation points corresponding changes in the temperature coefficient of resistance. On fusion, there occurs in general a discontinuity in the resistance-temperature curve, the liquid metal having usually from two to four times the resistance of the solid metal at the melting temperature. The proportionality between the electrical conductivity of pure metals in the crystalline solid state and the absolute temperature must be considered as only a very rough approximation. For a "perfect" metal the temperature coefficient of resistance is equal

to $\frac{1}{273}$, or 0.00366, reckoned from the value of resistance at 0 deg. C. Actually, the temperature-coefficient of most metals is greater than this.

In marked contrast to the metals in the solid state, the temperature coefficient of molten metals, reckoned from the melting temperature, is in practically all cases very much less than 0.00366. This fact, together with the abrupt increase in specific resistance on fusion, is sufficient to cause the resistance-temperature curve, extrapolated down to room temperature, to lie at a very considerable distance above the observed resistance-temperature curve of the solid metal, as shown schematically in Fig. 2, in which the dotted line would represent the electrical property of the amorphous solid metal.

CRYSTALLIZATION PROCESS IN SOLID SOLUTIONS

It is known that when a pure metal crystallizes from its melt there occurs a rearrangement of the atoms which results in the establishment of some definite configuration. If by suitable means a molten metal could be cooled below its melting point without rearrangement of its atomic structure, we would have a phenomenon too well exemplified in the case of the glasses, silicates, etc., to call for any detailed explanation here. A definite crystalline configuration would not appear, and with the exception of the property of viscosity the cooled melt would be similar in its properties to a liquid, or, in other words, it would be an amorphous solid. In the case of the common metals in a state of purity the formation of the amorphous solid phase by rapid cooling alone is not possible, due to the very great crystallizing power of these substances. Assuming, however, that supercooling sufficient to give the solid amorphous phase were possible, the question naturally arises as to what would be its most probable electrical properties. Reasoning from what information we have regarding certain of the other physical properties of supercooled liquids such as vapor pressure, we will hypothesize no break to exist at the melting point between the temperature-resistance curve of the liquid metal and that of the supercooled liquid or amorphous solid metal, and that the latter will possess likewise the same temperature coefficient of resistance

as the molten metal. For example, nickel,² with a temperature coefficient at its melting point (1452 deg. C.) of 0.000167 and a specific resistance at this temperature of 108 microhms per cu.cm. would be expected to show in the amorphous solid form at 20 deg. C. a specific resistance of 108 $[1 - (1430 \times 0.000167)]$, or 92.9 microhms per cu.cm. The computation is equivalent to an extrapolation of the resistance-temperature curve of the liquid metal down to ordinary temperatures.

Now, while we are unable by cooling alone to produce such a metal in the amorphous solid form, it is a well-known fact that by the addition of a certain amount of some such metal as chromium, capable of forming a continuous series of solid solutions³ with the nickel, the crystallization process at the melting point is very

FIG. 2. ILLUSTRATIVE EXAMPLE OF SPECIFIC RESISTANCE-TEMPERATURE CURVES OF A PURE METAL

greatly modified. If we consider the chromium primarily as an agent for the preservation of the molecular structure of the molten metal in the solid metal we would expect to find that the resulting nickel-chromium alloy would show a very high resistance, approximately equal to 92.9 microhms per cu.cm., and that its temperature coefficient would be small, about equal to 0.000167. The confirmation which this theory receives from the known data⁴ regarding nickel-chromium alloys is rather remarkable. A Ni-Cr alloy containing 20 per cent Cr has a specific resistance of 96.9 ohms per cu.cm. and a temperature coefficient of 0.00012 reckoned from room temperature.

Let us examine another well-known pair of metals known⁵ to form a continuous series of solid solutions viz., silver and gold. According to Matthiessen⁶ the

resistance-composition curve of this system has a shape typical of solid solutions. (See Fig. 1, curve A.) The highest value for specific resistance is equal to 11.42 microhms per cu.cm. at about 20 deg. C. Fortunately, the specific resistance and temperature coefficient for both silver and gold have been determined in the liquid state at their melting points. Northrup⁸ finds that liquid silver at its melting point (960.5 deg. C.) has a resistance of 16.6 microhms per cu.cm. and a temperature coefficient reckoned at this temperature of 0.00069; while liquid gold has a resistance of 30.82 microhms

FIG. 3. TEMPERATURE-RESISTANCE CURVE FOR GOLD AND SILVER, SOLID AND LIQUID (ACCORDING TO NORTHROP)

Dotted line represents electrical properties of amorphous solid gold and silver, according to theory advanced by the author.

per cu.cm. at its melting point (1063 deg. C.) and a temperature coefficient of 0.000459. Making our computations as before, we find that the specific resistance of "amorphous solid silver" at 20 deg. C. is calculated to be 5.29 microhms, and that of amorphous solid gold 16.09 microhms. (Fig. 3.) The mean of these two values is equal to 10.69 microhms, which checks very well with the observed value of 11.42 microhms. It appears then that the agreement between the calculated and observed values in the case of the system Ni-Cr discussed above may rationally be explained as due to the fact that the calculated value for amorphous solid chromium at 20 deg. happens to be about equal to that for nickel, a hypothesis not unlikely when taken in connection with the close atomic resemblance between the two metals.

Similar calculations can be made in the case of the system gold-copper, which has been shown⁹ to form a continuous series of solid solutions. The resistance of molten copper at its melting point (1082.6 deg. C.)

is given by Northrup¹⁰ as 21.30 microhms per cu.cm. with a temperature coefficient of 0.000381. The calculated resistance of amorphous solid copper at 20 deg. C. is equal to 12.67 microhms per cu.cm. The mean between this value and that of gold as previously arrived at, viz., 16.09 microhms, is equal to 14.38 microhms. According to the measurements of Matthiessen the maximum resistance at about 20 deg. of solid Au-Cu alloys is equal to 14.49 microhms per cu.cm. The agreement is correct to within less than 1 per cent.

The only remaining system for which the data needed for our calculations are available is the system Cu-Ni.¹¹ The mean of the values already given for the resistance of these two metals in the amorphous solid form is equal to

$$\frac{12.67 + 92.9}{2} = 52.78 \text{ microhms per cu.cm.}$$

According to the measurements of Fuessner and Lindeck¹² the specific resistance of the Cu-Ni alloy of maximum resistance is equal to 52.05 microhms per cu.cm. Table I contains a summary of the data for the four systems under consideration. The computation for the system Ni-Cr is included, although, to make it strictly comparable with the rest, it must be assumed that the specific resistance of solid amorphous chromium is approximately equal to that of nickel.

TABLE I.

Comparison of the observed values of maximum resistance at 20 deg. C of the systems Ni-Cr, Ag-Au, Au-Cu and Cu-Ni with the mean of the resistances of the amorphous solid components, obtained by extrapolation of the observed resistance-temperature curves of the components in the liquid state down to 20 deg. C.

System	(Values of resistance in microhms per cu.cm.)		Mean Value Calculated	Maximum Observed for Solid Solution
	Calculated Resistance of First-Named Metal in Amorphous Form at 20 Deg.	Calculated Resistance of Second Metal in Amorphous Form at 20 Deg. C.		
Ni-Cr	92.9	92.9 (assumed)	92.9	96.9
Ag-Au	5.29	16.09	10.69	11.42
Au-Cu	16.09	12.67	14.38	14.49
Cu-Ni	12.67	92.9	52.78	52.05

It would be expected that in the case of those alloys which form a simple eutectiferous series of alloys there would be no close agreement between the observed values and those calculated as above. The system Cu-Ag is an example of this. The calculated resistance in this case for the alloy of maximum resistance is equal to 8.98 microhms per cu.cm., whereas Matthiessen has obtained a value of 10.40 microhms by actual measurement.

CRYSTALLIZATION AN ELECTRONIC PHENOMENON

If it be found generally true then that the relationships to which attention has been called are exhibited by all those systems of metals which form solid solutions with one another, while on the contrary these relationships do not exist in the case of simple eutectic systems, then it is certain that the atomic processes operating during the passage of the melt from the solid to the liquid state, whether the former state be that of a crystalline or an amorphous solid, are governed entirely by the electrical properties of the atoms, which properties are determined, as we know, by the number of free electrons present and the distribution of their potential energy. The crystallization

process in metals, therefore, is an electronic phenomenon, and is not then very greatly removed in its nature from ordinary chemical reactions in which the electron structure is known to be the decisive factor.

A solid solution may then be regarded as entirely analogous to a supercooled liquid, preserving in the solid state all of the electrical properties, such as specific resistance and temperature coefficient of resistance, of the molten mixture of components. We are then at liberty to dispense with the theory that the high resistance of solid solution alloys is due to internal strain or to the closeness of packing of the atoms. Those facts which will explain the high resistance of the molten constituents will also explain the high resistance of solid solution at ordinary temperatures. Internal strain in liquid metals is hardly conceivable.

METALS OF APPROXIMATELY EQUI-ATOMIC VOLUME CONSIDERED IN TABLE I.

The agreement between the calculated and the observed values of resistance, as given in Table I, is so remarkably good that it leads us to inquire why the mean of the resistances of the components in the amorphous solid state should agree with the observed maximum resistance of the alloy. If the property of specific electrical resistance of the alloy were simply an additive function of the respective specific electrical resistances of the pure components, computed as being entirely in the solid amorphous state, then in binary systems, such as have been considered, we would expect the resistance-composition curve to be a straight line. It is certain then that is not the case. On the other hand, if the percentage of amorphous solid silver, say, in the system silver-gold is a function of the amount of silver (or gold) present in the alloy, we would obtain a resistance-temperature curve similar to that observed. It is indeed reasonable to suppose that the addition, say, of only 2 per cent gold to liquid silver is unable completely to inhibit the crystallization processes, or the rearrangement of atomic configuration, but that the inhibition increases rapidly as the percentage of added gold increases. If those forces brought into play to prevent atomic rearrangement at the melting point are essentially of interatomic nature, we would expect a maximum inhibition of crystallization when the atoms of the two metals were present in equal atomic proportions. The observed maximum of resistance should then correspond to equi-atomic percentages of the components. Since specific electrical resistance is referred to unit volume, the agreement between the observed and calculated values as shown in Table I indicates that the atomic volumes of each of the components of a binary solid solution system must be very nearly the same. The smaller the difference between the specific resistances of the two pure components in the amorphous solid form the greater can be the permissible variation between the atomic volumes of the components for a given difference between the observed and the theoretical values. (The term atomic volume refers here to the metal in the amorphous solid form, and will differ somewhat from the ordinary values for crystalline solids.) It is, of course, a well-known fact that, in general, the maximum in the resistance-composition, and also of the hardness-composition curve, occurs at very nearly equi-atomic percentages; and furthermore it is also recognized that solid solution is most common in pairs of metals having approximately the same atomic volume in the crystalline state.

There is, as has been indicated, a close connection between the hardness and electrical resistance of solid solution alloys, the general shape of the hardness-composition and resistance-composition curves being similar, and the maximum on each curve occurring at practically the same composition. (See Fig. 1, curve B.) According to our theory hardness in such an alloy is due to the existence of the metal in the amorphous solid state, thus confirming essentially Beilby's theory of the formation of an amorphous phase during cold-working of a metal.

In accordance with this view, gamma-iron is simply amorphous solid iron which is in solid solution with carbon. It should be similar in its electrical properties to molten iron. There can hardly be any basic difference between gamma-iron and the iron held in solid solution in manganese, nickel or tungsten steels. The high electrical resistance in both cases is evidence sufficient to place them in the same broad class which includes the four solid solution systems above mentioned, in spite of the fact that, particularly in the systems containing carbon, we may have solid solutions capable of transformation into the mechanical mixture characterizing eutectiferous alloys by a suitable heat treatment, or by slow cooling alone. If the resistance of liquid iron at its melting point were known, it would be possible from this value, together with the observed maximum resistance of chilled carbon steel of austenitic structure, to calculate the resistance of solid amorphous carbon of zero porosity. This information might be of considerable interest when compared with the observed resistance of different types of carbon and graphite.

Returning to the question of the hardness of metals and the formation of an amorphous phase, it is possible to make an estimate of the amount of solid amorphous phase present in pure metals in the hardened state from the observed resistance of hardened as compared with that of annealed specimens. The calculations carried out for Ag, Cu and Ni, using Broniewski and Rauschenplat's¹² measurements of electrical resistance of the hardened and annealed metals, are, in percentages of the amorphous solid metal: Ag 1.18 per cent, Cu 0.21 per cent and Ni 1.38 per cent. A very small amount of the amorphous metal is therefore able to account for the observed increase in electrical resistance on hardening.

DISCUSSION OF ANOMALOUS INSTANCES

The case of bismuth is peculiar. The resistance of annealed and of hardened electrolytic bismuth is respectively 107.5 and 126.3 microhms per cu.cm. at 0 deg. C., while that of solid amorphous bismuth at this temperature is equal to 109.4 microhms, using the measurements of Northrup and Suydam¹³ on molten bismuth. Hence it is difficult to explain the observed increase in electrical resistance on hardening unless we assume that at its melting point bismuth undergoes an allotropic change. This is in accord with the present ideas regarding this metal, which, as is well known, undergoes a decrease in resistance on melting instead of an increase, the only other metal which acts similarly being antimony. It might be added that these two metals form with each other a continuous series of solid solutions.

¹²Loc. cit.

¹³E. F. Northrup and V. A. Suydam, *J. Frank. Inst.*, 175, pp. 153-61 (1913).

The evidence brought forward in the present paper that the high electrical resistance of solid solution alloys is due to the retention in the solid state of the atomic structure of the liquid state would seem to establish the fact that the hardening of pure metals as well as the increased hardness of solid solutions over that of the pure components is due to the presence of amorphous solid metal. Hardening occurs when the metal is sheared beyond the elastic limit, and presumably during the time when flow occurs a certain portion of the metal is actually in the liquid state. In the case of such metals as lead, thallium and tin the transformation of the amorphous solid metal resulting from the rapid freezing of the liquid metal to the original crystalline metal occurs very rapidly and is completed within a short time. In the case of copper and nickel, for instance, the transformation of the amorphous phase to the crystalline is not complete. A dynamic equilibrium is finally set up during continuous cold working whereby the same amount of amorphous metal is converted to crystalline as is formed by the shearing processes.

It is unnecessary to call attention to the need of more complete data on the electrical resistance in the

liquid state of those metals which are able to form solid solution alloys, and also on the electrical resistance of their different alloys. Particularly in the case of Pt, Pd, Fe, Cr, Mn, Bi and Sb this information would be of much value in obtaining additional confirmation for the theory herein advanced. In the case of the metals Fe, Mn, Cr, V, Ti and Si experimental determinations of the specific resistance in the liquid state over a range of temperature would probably yield information of very great importance to the science of metallurgy and metallography, especially in so far as iron and steel is concerned. The use of electrical methods for investigating the properties of metals is older than either the thermal or the microscopic method. Assuming that we are able to grasp completely the essential principles underlying the electrical properties of metals—and it is believed that the theory advanced in the present paper is a step in the right direction—it can be predicted that the electrical method of examination will eventually become a very powerful instrument of industrial research and control, possessing also enormous possibilities from the purely scientific standpoint.

Cleveland, Ohio.

Hygroscopicity of Trinitrotoluene*

BY WILBERT J. HUFF

THE application of trinitrotoluene to the arts of peace is a matter of much interest and importance just now because of the huge stores of that material rendered available by the signing of the armistice. As an argument against such use it has been stated that trinitrotoluene is very "hygroscopic" (hygroscopic?) and that if used in place of dynamite for land clearing or drainage, extreme care must be exercised to keep it dry.¹

CALCULATED HYGROSCOPICITY

The allegation that trinitrotoluene is hygroscopic is, upon analysis, a most surprising one. The hygroscopicity of a crystalline compound not forming hydrates is determined by the vapor pressure of the saturated aqueous solution of the compound and the partial pressure of water in the surrounding atmosphere. While no measurements of the vapor pressures of saturated solutions of trinitrotoluene appear to be available, their order of magnitude may be readily calculated. The solubility of trinitrotoluene in water at 15 deg. C. is 0.021 per cent and at 100 deg. C. is 0.164 per cent.² Assuming the temperature-solubility curve to be linear (without introducing any appreciable error) and applying Raoult's law, the vapor pressure of such a solution at 25 deg. C. is 99.997 per cent of that of pure water at the same temperature. Since these, then, are almost equal, it follows that trinitrotoluene is practically not hygroscopic. It may be of interest to note that its hygroscopicity must be multiplied 2300 times to become equal to the hygroscopicity of potassium nitrate and 6900 times before it is necessary to pack it in paraffine-protected containers.³

The conclusion that trinitrotoluene is practically not hygroscopic is supported by the following statement from Molinari and Quartieri: "Il se conserve parfaitement inaltéré a l'air sec ou humide (son hygroscopicité est seulement de 0.05%) . . ." "It remains completely unchanged in dry or moist air (its hygroscopicity is only about 0.05%)."

LABORATORY DETERMINATIONS

Since three grades of solid trinitrotoluene are used in America, and because small quantities of water soluble impurities would affect their hygroscopic properties, it was deemed advisable to seek experimental confirmation by laboratory measurements of samples of the lower grades, using the method developed in this laboratory by Taylor and Cope.⁴

The only modification was the introduction of an inverted porcelain crucible cover, 3.4 cm. in diameter, 0.3 cm. in depth. The sample was spread uniformly over this and the whole then placed inside a slightly larger porcelain crucible.

To check the conditions used, the rate of moisture absorption by pure potassium perchlorate was determined at 25 deg. C. The results obtained are compared below with those previously determined by Taylor. The agreement is quite satisfactory.

The trinitrotoluene used was of two different grades, as follows:

	Grade II.	Grade III.
Manufacturer.....	Canadian Explosives, Ltd.	Hercules Powder Co.
Brand.....	Grade 2 TNT	76 deg. C. TNT, Grade III
Received from.....	Picatinny Gen. Ord. Depot	Rianton Arsenal
Laboratory No.....	M-2321	M-2328
Solidification point.....	80.3 deg. C.	76.5 deg. C.
Moisture.....	0.02 per cent	0.03 per cent
Insoluble matter.....	0.156 per cent	0.04 per cent
Ash.....	0.008 per cent	0.014 per cent
Acidity (H ₂ SO ₄).....	0.002 per cent	0.014 per cent
Color imparted to water	Fale straw	Fale straw to rose

This was carefully dried in a vacuum desiccator, then 2.0000 g. weighed into the crucible, allowed to stand for 24 hr. over concentrated sulphuric acid, reweighed

* Taken from "The Hygroscopic Properties of Black Powder," by Dr. G. B. Taylor

While the gains in weight observed are extremely small, they are of the same order of magnitude as that found for potassium perchlorate.

Now the calculated vapor pressure of saturated solutions of potassium perchlorate at 20 deg. C. is 99.7 per cent of that of pure water.⁴ Theoretically, then, potassium perchlorate should deliquesce about 100 times more rapidly than does trinitrotoluene. At first glance, the experimental results seem to contradict this and suggest the presence of water-soluble impurities in the trinitrotoluene. To remove any such impurities a quantity of Grade III trinitrotoluene was twice washed by melting it and agitating it for 1 hr. under five times its volume of distilled water. The tests upon this still show gains of approximately the same magnitude.

Tests made with empty crucibles and with crucibles containing 3.0000 g. of carefully washed and dried ground glass (35 to 45 mesh) show conclusively that the gain in weight is due almost entirely to thin films of water deposited on the surfaces of the crucibles and material. This deposition is probably caused both by surface adsorption and by condensation attending the minute but inevitable temperature fluctuations in the thermostat.

The method of Taylor and Cope, therefore, appears to be unsuited for the determination of hygroscopicities less than that of potassium perchlorate.

The experimental results do show, however, that trinitrotoluene is practically non-hygroscopic and are herewith published to controvert the current misleading statements to the contrary.

Explosives Chemical Laboratory,
Bureau of Mines, Pittsburgh, Pa.

*Marshall, *loc. cit.*, p. 341. The experimental data of Taylor and of Cope and Taylor at 25 deg. are in accord with this calculated value.

Belgium for many years was the principal zinc producing country of the world. Gradually its production was surpassed by that of Germany, and Germany in turn lost first place by the production in the United States. For the ten years previous to 1914, 21.6 per cent of the world's zinc was produced in Belgium. Of this production approximately 40 per cent was exported. A large percentage of the balance was rolled and of the sheets thus produced a considerable quantity was also exported.

From an economic standpoint even before the war, the Belgian zinc industry was in a unique, if not precarious, position. Dependent upon foreign countries for ore and foreign markets for sale of products, the Belgian smelter was at a distinct disadvantage when compared with some of those of other localities. These disadvantages were partly offset by cheap coal and labor and by whatever there is of value in experience and what we may term for want of a better expression "smelting tradition." However intangible this latter may be, it did have and has today an influence on commercial operations.

One must not overlook the effect it will have on the revival of the industry. It may not be the determining factor, but the fact that for so many years this industry flourished in Belgium and played such an important rôle in the industrial life of the country will decide many operators to attempt to re-establish their operations.

In 1913 the Belgian zinc plants produced 204,220 long tons of zinc, or approximately 20 per cent of the world's production. During that year 500,000 tons of ore were treated. The actual value of all of the products derived from treating zinc ore amounted to 225 million francs. In 1918, the production had dropped to 8,000 tons with a corresponding drop in the value of the products.

The general custom in Belgium has been to roast zinc ores at chemical works and then transport the roasted ore to the smelting plants. Only 4 out of the 14 smelting plants have roasting plants attached. The total capacity of these 4 smelter roasting plants was 100,000 tons of ore per year. There were 10 chemical works having a zinc ore roasting capacity capable of treating somewhat over 300,000 tons a year. Because of obtaining such a large amount of Australian ore, it is quite natural that the development of the smelting practice should have been along the lines of recovering the lead and silver values from the furnace residues. Two plants were equipped to treat the residues producing lead and also refined silver.

Table I gives the record of operations for the years 1913 to 1918.

TABLE I. YEARLY PRODUCTION OF ZINC IN BELGIUM, 1913-18

Year	Number of Retorts	Number of Workers	Tons of Coal	Ore Treated, Tons	Zinc Produced, Tons
1913	43,434	8,539	998,655	468,730	204,220
1914	30,765	8,142	715,815	340,700	147,925
1915	10,448	4,397	262,020	124,890	51,668
1916	5,182	4,044	142,020	59,750	22,939
1917	1,898	1,586			10,296
1918	1,000				8,000

During the 53 months of the war there was produced 34,000 tons of sheet zinc.

The principal source of ore was Australia. In 1913,

*Bureau of Mines Minerals Investigations Series, No. 18.

out of a total of 495,760 tons of ore used, 840 tons came from Belgium, 488,035 from foreign countries, of the foreign ore, 175,000 came from Australia, and 6895 from oxide and refuse. Of the 480,000 tons

Official published figures of the Department of Mines of Belgium for 1913 show that in that year there were 14 plants, with 43,253 retorts; the number of workers was 8444; and the production was 205,940 tons. There were 10 rolling mills, with 34 rolls and 742 workers. The production was 49,120 tons.

Most of the companies obtained their ore through German brokers. Only one company had any direct supply of its own. The fact that the ore was furnished in this way, with the control of the metal lodged more or less completely in the hands of the interests furnishing the ore, has certainly not contributed to a rational development of the industry.

In addition to the Australian ore, one company imported a considerable tonnage each year from Sweden and from Sardinia. The Swedish ore will undoubtedly continue to go to Belgium. The freight rate at the present time from Sardinia is so excessive, being as high at times as £7 sterling, that it is problematical whether much of this ore can be used; although the freight rate from Australia is also high, ore from there carries lead and silver values, so that it can better stand the advanced rates.

The only ore supply in sight for Belgian smelters at present, outside of Sweden, is Australia, with a possibility in the future of getting some ore from Mexico, as with the return of conditions approaching those of the pre-war period the Belgians may be able to compete in the Mexican ore market.

NAPOLEON GAVE SUBSIDIES FOR EXPERIMENTAL WORK

The present method of zinc distillation originated in the city of Liège, where the ores from Moresnet, the former neutral territory between Germany and Belgium, were treated. The original experimental work was paid for by subsidies granted by Napoleon I. An interesting historical account of the first attempts to produce zinc from these ores is given in one of the recent reports of the Vieille Montagne Co. This company controls the mines at Moresnet, and until the outbreak of the war was the largest producer in Belgium and one of the largest in the world, having a yearly production from all plants of over 100,000 long tons. For the last hundred years, Liège has always been the principal smelting district in Belgium. The works in this district are for the most part on the Meuse River and obtain their coal from the Liège field, having both rail and water transportation from the mines to the plants.

The only lead furnaces in the Liège district were at the Dumont Frères plant. These furnaces were completely destroyed. Aside from quite an extensive installation at Overpelt, which included, in addition to the lead furnaces, silver-refining furnaces, the rest of the lead smelting is done in the eastern part of the country.

The roasting plants, except those of Prayon and Dumont, are near the seaboard, and the roasted ore is carried by canal boats to the smelting works. The country is so small that the internal transportation cost has never been much of an item, but in order to effect every saving possible, zinc smelters have taken advantage of the highly developed waterway facilities of the country.

There are 14 smelting plants with a total of 50,696 retorts, 10 rolling mills, with a combined capacity of

52,000 tons, and 10 chemical plants for roasting ores. Detailed data are given in Table II.

TABLE II. LOCATION AND CAPACITY OF BELGIAN SMELTERS AND ROLLING MILLS

LARGE FURNACES NOT FAVORED

About 60 per cent of the smelting capacity can be said to be of modern construction. A plant at Rothen, with 3360 retorts, was completed just before the war, and one at Corphalie, with 2200 retorts, was built during the war. The tendency in the newer plants has been to increase to a considerable extent the mechanical handling of ores and also the mechanical charging and discharging of the furnaces. The Belgian engineers have never looked with favor on the use of the large furnaces so common in this country. The furnace generally used is one that has not over 200 retorts to the side, and it is only in the recently built plants that one finds the separate producers used, and in only a limited number have mechanical producers been used. The working floors of the furnace rooms are well ventilated and the hoods over the furnaces are connected with stacks for carrying away the zinc fumes from the furnaces.

The furnace blocks, as stated, are small and in all but one plant are placed end to end with considerable distances between the ends of adjoining furnaces. One plant recently constructed has compartment furnaces of the regenerative type, with separate air control in the different compartments of the furnaces. This type of furnace is much commended and will most likely be adopted in future rebuilding of furnaces.

The general character of building with one or two minor exceptions compares favorably with the more modern smelters in the United States. The ground space used per unit of capacity is considerably less than in this country. While the actual construction is of a permanent and substantial character, a number of the plants are poorly arranged and equipped, so that with high priced labor the smelting costs of these particular plants are apt to be much beyond a figure that will be obtained in British and American works.

The practice in regard to roasting has been to use hand-raked furnaces, only two attempts having been made to depart from this rule. At one plant five Spirlet furnaces were put up and at another plant a modified Hegler is now under construction.

While the mechanical or semi-mechanical roasting

furnaces used in this country have not been entirely successful, still they do use less labor per ton of ore roasted than the hand-raked furnaces, and with increasing cost of labor the Belgian plants will be at a serious disadvantage, even after allowances are made for lower fuel consumption and smaller dust losses. The latest installation of roasting furnaces was that put in at the Coleman chemical plant just before the outbreak of the war. These furnaces are of the Delplace type and were operated for a short time only, as during the war the acid works at this plant used pyrite as a source of sulphur. In the last days of fighting, in November, 1918, this plant was completely wrecked. The furnaces themselves were not destroyed, but the lead chambers and other parts of the plant were greatly damaged, not only through shell fire but through removal of equipment and material.

FUTURE OF THE INDUSTRY NOT BRIGHT

The principal reason for the extensive smelting of zinc ores in Belgium was the fact that the country had an abundance of cheap and skilled labor, the proper quality of clay for retorts, cheap coal and cheap water transportation. Of these four factors, probably the most important was that of labor. The past four and a half years of enforced idleness, together with the removal of many of the workers from towns near the smelting plants, has resulted in a thorough disorganization and demoralized condition of labor, and its effect will be felt for some time in the industry, both in respect to the efficiency of the operations and also in the labor cost. The future of Belgium as a zinc-producing country is not particularly bright, but the relative position it will occupy from now on is not easily predicted.

It is rather certain that for some years to come production will be far below the pre-war figures and may never reach the 1913 level. The rehabilitation of the industry even to a limited extent will depend upon the obtaining of prompt and reasonable supplies of ore. If these are not promptly provided, the greatest asset that Belgium had, that is, the skilled workmen, will be lost, as these men undoubtedly will seek employment either in other countries or in other industries. The smelting capacity outside of Belgium has been so vastly increased that it can easily take care of the world's requirements and only the plants that are in a position to operate on low cost and high recovery can hope to compete successfully. The present cost of coal will no doubt come down, but the political and commercial control of the primary raw material, being outside of Belgium, will always work against the continuance of the industry. One factor that will be helpful, however, will be a profitable market for the by-products. This may compensate to a considerable extent for the disadvantages under which the industry will otherwise be. Unfortunately the lead-chamber acid plants throughout the country were completely dismantled by the Germans, and some time must elapse before they can be rebuilt.

Aside from commercial considerations the present physical condition of the plants will tend to retard the resumption of operations. With the exception of the Coleman plant, the plants in Belgium connected with the zinc industry were outside of the fighting area. This, however, did not prevent a large amount of physical destruction.

MUCH PROPERTY DESTROYED AND EQUIPMENT REMOVED

During the last two years of the occupation, the idle plants suffered largely from lack of maintenance and from equipment of all kinds removed. To obtain lead, the towers and chambers of the sulphuric acid plants were dismantled. This, of course, prevents an early resumption of roasting. Much property was destroyed to get cast iron, copper, and steel scrap. Rolling stock, machinery, belting and practically all of the copper transmission lines were removed from all of the plants. Naturally there was some distinction made in the character of material removed from the plants that were German owned and those owned by the Belgians. The former operated to a limited extent during the entire period of occupation and are in fair shape to resume work on an extensive scale.

The plant of the Dumont Frères on the Meuse River at Sielles, consisting of a roasting and acid plant, a spelter plant, a cinder concentrating plant, six lead furnaces and a refining plant for refining base bullion, was seriously damaged. Some of the buildings were left, but the metallurgical equipment was completely destroyed or removed. Other plants were damaged to a limited extent only, and most of the damage consisted of the removal of equipment and materials that could ordinarily—with the exception of lead chambers—be replaced within a comparatively short time. Of course the furnaces will have to be relined and many will have to be rebuilt on account of remaining idle for such a length of time.

The ore stocks were generally removed to the German plants in Belgium. Serious attempts were made to keep these running in part; nevertheless, even these suffered very considerably from careless operation.

To summarize briefly the situation, the smelting practice in Belgium has been developed along the lines of treating the ores so as to extract the greatest amount of metal values and to produce products that are most readily salable; thus large quantities of sheet zinc and zinc oxide have been produced.

Most attention has been given to transportation, quantities of raw materials used and maintenance of plants. While working conditions have not been neglected where they would affect the recoveries, the labor involved in the operations has not been considered to the extent common in this country, and the result is that the man-days per ton of ore treated are considerably in excess of those employed in this country. To this particular point attention will now have to be directed. Even before the war, it was becoming evident that further reductions in smelting cost must be made, and the Belgian engineers were turning their attention to this problem in regard to the labor required for roasting and also for furnace operations.

The Belgian engineers have contributed largely to the metallurgy of zinc, and while they are now handicapped in so many ways, it is entirely within the realm of possibility that they can meet the situation and restore the industry to a fair percentage of what it was before the war.

The longer this restoration is delayed the more difficult the problem becomes. The extent to which the smelting of zinc ore will be restored in Belgium is largely a matter of the time that it takes to get any of the operations under way.

strument transformers and the main service switch are led to a 4-pole, double-throw oil switch. This is so connected that when the switch is thrown in one direction (see Fig. 1) both transformers (and their regulators) are connected in multiple to one phase. When the switch is in the other position one transformer and its regulator are connected to one phase and the other transformer and regulator to the other.

The four coils of each transformer and its corresponding regulator coils are connected to knife switches on the switchboard. These are in two sets,

which the regulators are "boosting" their maximum, i.e., at 121, 242, 484 volts. Many types of commercial furnaces require less than this maximum amount of power, and semi-commercial sizes of all types come within the capacity of this installation.

The instruments include an ammeter for each phase, a low-tension and high-tension voltmeter with the receptacles and plugs for reading the voltages on either phase, a two-phase power factor meter, a graphic wattmeter, and an indicating wattmeter. The watt-hour meters supplied by the city lighting de-

FIG. 2. WIRING DIAGRAM FOR SWITCHBOARD.

the upper set of two single-pole and three double-pole switches being connected to transformer A and feeding the upper set of bus bars, the lower set feeding the lower bus bar. The switches are so arranged that coils of the transformer-regulator combinations may be connected either all in series or in multiple or in two multiple series of two each.

For example, referring to Fig. 2, if the single-throw switches on transformer leads P and I are closed, and if the three double-throw switches between them are closed to the top, the four transformer coils are in multiple and every bus of the ten served by the transformer is of opposite polarity to its neighboring buses. If the single-throw switches are closed and the double switches are thrown down, the transformer coils are in series with alternate polarity with buses as before. Finally if the single-throw switches are closed, and the double-throw switches on leads O, N, K and J are thrown down but that on leads M and L thrown up, the coils between M and N, and P and O are in series with each other, but in multiple with the similar series combination of coils between L and K, and J and I. The amount of current that may be delivered, either all on one phase or equally distributed between two phases, is thus 3600 amp. at any voltage between 35 and 121, all the coils being in multiple; 1800 amp. between 121 and 242 volts when the coils are in multiple series; or 900 volts between 242 and 484 volts, when the coils would be in series.

The actual power capacity of the installation varies with the voltage and ranges from 126 kilovolt-amperes when the regulators are "bucking" their maximum amounts to 436 kilovolt-amperes at voltages at

partment, which are not shown in Fig. 2, are also mounted on the switchboard.

The bus bars are carried on pipe frames and are surrounded with expanded metal grille-work to prevent accidental contact with them. The sections of

FIG. 3. SWITCHBOARD

this grille-work may be removed and suitable connections made to the bus bars in accordance with the requirements of the particular furnace being supplied with power. The buses are closely spaced; this and the alternation of polarity reduce the reactance to a minimum.

Among the accessory apparatus are a Leeds Northrup optical pyrometer, and a Beighlee three-station, recording pyrometer system. The recording instrument of the latter is mounted on a bench conveniently adjacent to the switchboard. Stocks of electrodes, refractories, electrode holders, cables and similar requisites are on hand to provide the materials for the erection or modification of furnaces.

FIG. 4. REAR OF SWITCHBOARD.

The requirements of a source of energy for experimental electric furnaces are that it must be flexible, easily controlled, and capable of delivering ample power. The range in voltage possible in this installation is such as to give extreme flexibility. Merely pressing push buttons on the switchboard provides for voltage variation within wide limits; simpler control can hardly be imagined. Finally, the capacity is such as to provide for furnaces ranging in size from the smallest to that of commercial or semi-commercial ones.

In this case, as in others, the customary policy of the Bureau will be followed, which permits, under suitable co-operative agreements, the use of its equipment by outside interests, when so doing does not result to the detriment of its own investigations. In this way there is made available, for those not having suitable facilities of their own, a group of apparatus which is believed to be remarkably adaptable

Allis-Chalmers Forge Shop

ABOUT twelve years ago the Allis-Chalmers Manufacturing Co. of Milwaukee, in the development of its large units for steam, electric and hydraulic plants, was face to face with the necessity of either going to the large forging plants in the East (or even to Krupps) for the large forgings required, which would necessitate delay and inconvenience as well as interfering very materially with deliveries; or spending a large sum of money and putting in a forge plant large enough to take care of this heavy forge work. The management decided on the latter course, immediately planning a new forge shop and designing it to take care of some future expansion by installing a 3000-ton hydraulic press of the steam intensifier type. Later a 1000-ton press and a series of various sized hammers were added. This gave the company more capacity than it required for its own needs, as it went into the market to sell heavy forgings, either rough forged, rough machined or finish machined.

On the 3000-ton press, forgings can be made up to 40 tons weight. This means that an ingot must be used weighing 55 to 60 tons, for the reason that the upper 20 to 30 per cent of the ingot must be discarded on account of being piped due to shrinkage in cooling. Within this weight shafts up to 60 ft. long or up to 48 in. diameter can be forged, heat treated and machined.

To satisfy the requirements of the engineering departments it was necessary to build a heat-treating plant. In this plant are 3 car type box furnaces 8 x 12 x 16 ft., 2 car type furnaces 6 x 8 x 30 ft., 2 car type furnaces 6 x 8 x 45 ft., 1 car type furnace 6 x 8 x 50 ft., 1 open top furnace 5 x 7 x 16 ft., and 1 open top furnace 6 x 8 x 50 ft., and many others of smaller dimensions. All of these horizontal furnaces are of the semi-muffle car type. For the heat treatment of the hollow shafts, two large semi-muffle vertical furnaces are provided, one being 14 ft. diameter by 70 ft.

INTERIOR OF HEAT-TREATING PLANT, SHOWING LARGE VERTICAL FURNACES AND QUENCHING TANKS

ROUGH FORGING FOR NO. 27 GYRATORY CRUISER SPINDLE

HOT INGOT BETWEEN ANVILS OF 3000-TON HYDRAULIC PRESS

high, for treating shafts up to 60 ft. long, the other being the same diameter and 50 ft. high.

There are also horizontal and vertical quenching tanks in which the largest forgings can be handled, the largest vertical tank being 14 ft. diameter by 75 ft. deep.

A large stock of billets and ingots are carried in stock, billets up to 24 in. x 24 in. x 12 ft. long and ingots from 14 in. diameter up to 62 in. diameter weighing 60 tons. These are of low, medium and high carbon, nickel steel, vanadium steel, chrome-vanadium, and chrome-nickel steel. The alloy steels are carried in different analyses, and may be oil tempered or heat treated to meet a wide variety of requirements.

Heating furnaces are all equipped with the latest type Leeds & Northrup recording pyrometers and arranged to get temperature readings every few feet on the length of the forging from either side or from the top every few minutes. The indicators are installed in a central pyrometer room, where the temperature is continually under observation by expert metallurgists.

This line of work has developed side by side with the forging development until the Allis-Chalmers Manufacturing Co. now has one of the most complete plants in the country and is in a position to meet the most stringent requirements of U. S. Navy, Army,

Ordnance Departments, American Bureau of Shipping, Lloyds Survey and American Society of Testing Materials.

When war broke out the company was in splendid shape to take on work for the U. S. Government and the Emergency Fleet, and therefore took on some very large orders which kept it busy twenty-four hours per day until the armistice was signed.

In the list of forgings made by the company during the war period appear guns, and tubes, torpedo cylinders, recoil cylinders and pistons for largest Navy guns; shafting for battleships, cruisers and destroyers; shafting, connecting rods, rudder stocks, etc., for the Emergency Fleet.

Government Disposes of TNT

Disposition has been made of the 29,000,000 lb. of TNT which was declared surplus shortly after the signing of the armistice. At that time the War Department expressed the opinion that the surplus was so great that a portion of it had best be dumped into the ocean. The Bureau of Mines, however, suggested at that time that it would be possible to utilize the explosive in road and reclamation work in which the Government is interested. This resulted in legislation turning over the TNT to that bureau. That all of it should be allotted within 11 months after the armistice, however, came as a surprise even to the Bureau of Mines officials.

Of the 14,000,000 lb. actually distributed, 9,000,000 has gone to the Bureau of Public Roads, for use on Federal aid projects; 2,000,000 has been turned over to the Forest Service, for road work on the reserves under its jurisdiction, and the remainder has been used by the Reclamation Service, the National Park Service and the Indian Office.

While under ordinary conditions it is regarded as improbable that TNT could compete commercially with dynamite, a great saving to the people has been made by the use of this surplus explosive. In road work contractors have allowed from 20 to 25c. per cu.yd. of the material to be removed by blasting. While that amount does not represent the full value of the explosive, it is considerably in excess of the 12½c. per lb. offer made for a portion of the surplus.

1000-TON HYDRAULIC PRESS

Synopsis of Recent Chemical and Metallurgical Literature

Acetic Acid and Acetone From Calcium Carbide.—The August, 1919, issue of the *Canadian Chemical Journal* is devoted to the chemical and electrochemical industries of Shawinigan Falls, Quebec. Possibly the most interesting chemical development at Shawinigan and one of the notable achievements in the chemical world during the period of the war has been the manufacture of acetic oxide and acetone from calcium carbide.¹

Experimental work was started in December, 1915, a plant (covering 15 acres) was completed in January, 1917, and the first car of acetone was shipped to the British War Ministry early in January.

The process may be divided into five stages:

1. Production of acetylene from calcium carbide.
2. Production of mercuric acid from metallic mercury.
3. Production of acetaldehyde from acetylene.
4. Oxidation of acetaldehyde to acetic acid.
5. Conversion of acetic acid into acetone.

The production of acetylene had previously been carried out only on a small scale, involving the generation of a few hundred cubic feet per day for town lighting. The process at hand called for 500,000 to 600,000 cu.ft. per day. After considerable experimentation, a generator was developed which was capable of handling half a ton of carbide at a single charge. By the end of 1916, a plant was constructed having a capacity of 600,000 cu.ft. per day. At present, the plant can deliver 1,200,000 cu.ft. of acetylene per day.

Mercuric oxide is the catalyst required in the conversion of acetylene into acetaldehyde. Since the cost of producing the oxide from the nitrate was prohibitive, an electrolytic oxidation method was developed. The cell consists of a cast-iron pot, 6 ft. in diameter, 15 in. high, with a stirrer sweeping the surface of the mercury (which forms the anode) to remove the oxide as formed. The electrolyte employed is caustic soda solution and the mercuric oxide is removed in suspension in the electrolyte. The oxide is allowed to settle in tanks and is used in a wet condition.

In the next step, which consists of passing acetylene gas into dilute sulphuric acid solution in which mercuric oxide is held in suspension by vigorous stirring, the most difficult problem was to find an engineering material which would withstand the action of the acid and at the same time resist the amalgamating action of the mercury. A special silicon iron of sufficient mechanical strength was developed for this purpose. By the use of a large excess of acetylene, the aldehyde is removed continuously. During the process, the mercuric oxide is reduced to a fine sludge containing mercuric organic compounds. The recovery of the mercury from this sludge was a difficult problem because of the nature and poisonous character of the material.

For the oxidation of acetaldehyde to acetic acid, a process was developed, using air (it was found im-

possible to secure Claude or Linde compressors to furnish oxygen) and a specially designed aluminum-lined conversion kettle. Copper, iron, etc., were found to act as surface catalysts, causing violent explosions. The acetic acid obtained is about 98 per cent pure and yields glacial acetic acid by a single distillation. About 30 tons of nitrogen is obtained every day as a by-product. No use is made of this at present.

The catalyst finally selected for the last operation—the conversion of acetic acid into acetone—was hydrated lime containing a small amount of magnesia. The conversion chamber was a steel tube, 13 ft. long and 12 in. diameter, electrically heated by means of resistance ribbons, and filled with rough cast-iron balls coated with a paste of the catalyst. Seventy-two of these tubes were installed for the production of ten tons of acetone per day. The temperature employed was 485 deg. C. and the average efficiency over a period of months was 85 per cent. The mixture of acetone, water vapor and unconverted acetic acid was passed through scrubbers containing soda-ash solution, maintained at 98 deg. C. by the heat from the gases. This removed the acetic acid vapors, while the acetone and water vapor passed to the condensers, where a 20 per cent aqueous solution of acetone was obtained, which was rectified in a regular continuous acetone still.

Graphical Representation of the Composition and Properties of Fuels.—In the *Technische Rundschau*, Berlin, for Aug. 6, 1919, Dr. K. SCHREBER treats graphically of the composition and properties of fuels. The latest investigations have shown that our fuels never contain pure carbon, even those richest in carbon, but always consist of hydrocarbons which are poor or rich in carbon. No one has yet succeeded in separating these hydrocarbons from each other, and we can only, at present, regard the fuels as homogeneous substances, and investigate their composition *en masse*.

It has been found advisable to consider the real fuel as consisting of carbon, hydrogen and oxygen, leaving out the ash and the moisture evaporated at about 100 deg. C., considering them as accidental or non-essential constituents. The percentage composition of the real or pure fuel is thus calculated, and since there are only three essential constituents it can be graphically placed on a triangular diagram such as is used in chemical and metallurgical investigations. Since the properties of the fuel are dependent on the proportions of these three fundamental elements, fuels of like properties should come in the same regions of the diagram.

When such a calculation and diagram is made for the common fuels, it is found that they do not group themselves satisfactorily according to properties. The tar oils and the petroleum oils, for instance, come close together on the diagram, although they have very different properties, and the same is true of other fuels; in other words, placing on the diagram according to percentage composition by weight does not lead to satisfactory differentiation of the various fuels.

However, modern chemistry is teaching us that the properties of compound substances are dependent primarily upon the relative number of the atoms of the different elements entering into their composition. These relative numbers of the constituent atoms can be easily obtained by dividing the percentage of each

¹"The Work of the Canadian Electro Products Company in the Synthetic Production of Acetic Acid and Acetone From Calcium Carbide," H. W. Matheson, *Canadian Chemical Journal*, August, 1919, p. 258.

element by the atomic weight of that element. For example, if a pure fuel contains 91.5 per cent carbon, 4.3 per cent hydrogen and 4.2 per cent oxygen, and the relative atomic weights of these three elements are 12, 1 and 16, respectively, then the quotients indicated will represent the relative numbers of the atoms of these elements present in the fuel. These relative numbers can be transformed into parts in 100, which are then called the *atomic percentage composition*. The arithmetical calculation is as follows:

Gravimetric Percentage	Atomic Weights	Atomic Composition
C 91.5 percent	12	$\frac{7.53}{12} = 0.626$ percent
H 4.3 percent	1	$\frac{4.30}{1} = 4.30$ percent
O 4.2 percent	16	$\frac{0.26}{16} = 0.016$ percent
		12.09 100.0

In the following table, the characteristic composition of 16 typical pure fuels is given, first in percentage by weight and next in atomic percentages; the last column gives the ratio of number of atoms of hydrogen to those of carbon.

No. on Chart	Fuel	Weight Percentage	Atomic Percentage	H/C Ratio
		C H O	C H O	
1	Anthracite	91.5 4.3 4.2	62.6 35.3 2.1	0.564
2	Short-flame bit.	89.5 5.0 5.5	58.3 39.0 2.7	0.670
3	Blacksmith coal	86.5 5.3 8.2	55.4 40.7 3.9	0.733
4	Long-flame bit.	82.5 5.4 12.1	52.8 41.4 5.8	0.784
5	Non-coking bit.	77.5 5.0 17.5	51.5 39.8 8.7	0.773
6	Coke	95.2 0.9 3.9	87.4 10.0 2.6	0.115
7	Brown coal	74.1 5.6 20.3	47.4 42.9 9.7	0.905
8	Turf, peat	59.9 6.1 34.0	37.6 46.2 16.2	1.230
9	Wood	50.0 6.0 44.0	32.3 46.4 21.3	1.437
10	Penna. crude petroleum	84.9 13.7 1.4	33.9 65.7 0.4	1.938
11	Russian crude petroleum	86.6 12.3 1.1	36.8 62.8 0.4	1.708
12	Kerosene	85.3 14.2 0.5	33.5 66.6 0.1	2.000
13	Inclined-coke-tar oven	89.4 5.0 5.6	58.2 39.1 2.7	0.672
14	Vertical-coke-tar oven	89.5 6.6 3.9	52.2 46.1 1.7	0.883
15	Retort-coke-tar oven	88.2 6.9 4.9	50.5 47.4 2.1	0.930
16	Retort-coke-tar oven	90.8 5.6 3.6	56.5 41.8 1.7	0.740

On the accompanying tri-axial diagram, the solid points represent the position of the weight percentages, while the small circles represent the atomic percentages. It is easily seen that the latter gains

a much better distribution into groups than the former, bringing together into the same locality on the diagram the fuels of similar properties. The atomic hydrogen percentage, in particular, seems to regulate the distribution into groups which correspond to similar behavior during combustion. The nearly flameless coals congregate around the carbon corner, while those with short or long flames pass toward the hydrogen corner the longer their name.

Recent Chemical and Metallurgical Patents

British Patents

Complete specifications of any British patents may be obtained by sending 25c. each to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Vegetable Charcoal.—Vegetable charcoal for filtering, deodorizing or decolorizing purposes is prepared by mixing pine and like needles with from 1 to 5 per cent of lime or soda-lime, carbonizing at a bright red heat, treating with dilute hydrochloric acid, and finally washing with water or with a dilute alkaline solution. The lime may be replaced by somewhat more than an equivalent amount of calcium carbonate. (British Patent 122,465—1918. G. PENROSE, 85 Brondesbury Villas, Maida Vale, London, and J. D. PENROSE, Oxley Grange, Watford. March 26, 1919.)

Dimethyl Sulphate.—Dimethyl sulphate is prepared by the reaction of sulphur trioxide on dimethyl ether in the presence of a solvent or diluent, preferably dimethyl sulphate itself. The sulphur trioxide used is preferably diluted with an indifferent gas; thus a current of air may be passed through hot fuming sulphuric acid and the resulting mixture of air and sulphur trioxide used, or the mixture of air, sulphur dioxide and sulphur trioxide resulting from the contact process of making sulphur trioxide may be used. The product of the reaction is treated either with ice or preferably with a reducing agent such as iron filings to destroy any sulphur trioxide present and is purified by distillation in vacuo. (British Patent 122,498—1918. W. N. HAWORTH and J. C. IRVINE, University St. Andrews, Fifeshire. March 26, 1919.)

Parchmentized Paper.—Paper is parchmentized and rendered waterproof, acid proof and of great strength by passing it through two baths of sulphuric acid or sulphuric acid mixed with sulphurous acid, the second being more dilute than the first, the acid being squeezed out after each operation, the paper being afterward neutralized by means of an alkali bath, washed, softened by means of a bath of glycerine, calcium chloride, salt or the like with or without admixed loading material and then dried. (British Patent 123,594—1918. W. DAGNALL, 26 Sandy Lane, Hampton Wick, Middlesex. April 26, 1919.)

Synthetic Preparation of Ammonia and Cyanogen Compounds.—The synthesis of ammonia, ammonium cyanide, and hydrocyanic acid by means of the action of electric arcs, sparks, or silent discharges on mixtures such as nitrogen and hydrogen; nitrogen and hydrocarbons; nitrogen, carbon monoxide, and hydrogen; nitrogen and water gas; producer gas and hydrogen; and illuminating gas and hydrogen, is effected under a pressure less than 200 mm. of mercury. An excess of nitrogen may be employed, and when carbon compounds are used hydrogen may be added to avoid the production of soot. The electrodes and armatures may be cooled, and the gases may be cooled immediately after the electrical treatment. (British Patent 123,760—1918. GROS & BOUCHARDY, 39 rue Camlon, Paris assignees of E. BRINER and A. BAERFUSS, Geneva, Switzerland. April 30, 1919.)

Recovering Brass.—Brass is recovered from foundry ash and the like remaining in the crucibles, etc., after the brass has been poured therefrom, by heating the ash to 1050-1250 deg. C. and stirring or kneading the mass so long as the molten brass continues to collect. A flux such as borax, glass, or soda ash may be used, and copper may be recovered from the resulting slag electrolytically. A reducing agent such as charcoal or carbon copper may be mixed with the ash. (British Patent 124,019—1918. C. H. WHITE, Park Road, Coventry. May 7, 1919.)

Dissolving Cellulose.—Solutions or viscous or gelatinous masses are obtained by treating cotton or other cellulose with solutions of thiocyanates, such as those of calcium, manganese, strontium or lithium. Thiocyanates which are insoluble or sparingly soluble, such as mercury thiocyanate, may be used in conjunction with those which are more soluble, such as sodium thiocyanate. Salts such as calcium chloride, or salts which dissolve cellulose, or acids such as acetic, may be added to the solution. (British Patent 123,784—1918. MANCHESTER OXIDE Co. and R. H. CLAYTON, Canal St., Miles Platting, Manchester; J. HUEBNER, Linden, Cheadle Hulme, Cheshire, and H. E. WILLIAMS, 19 Chattam Road, Withington, Manchester. April 30, 1919.)

American Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Electric Furnace.—IVAR RENNERFELT, of Djursholm, Sweden, improves the construction and design of an electric-arc-furnace for melting metals, glass, enamels and other materials in crucibles. The furnace is illustrated in Figs. 1 and 2. Fig. 1 is a vertical section taken at lines *y-y* in Fig. 2, which is a horizontal section taken at the lines *x-x* in Fig. 1. The vertical electrode (1) extends through the roof, making

Fig. 1.

Fig. 2.

an arc (7) with the granular carbon or graphite (6) contained in the carbon block (5). The crucibles (9) are heated by radiation from the arc and by reverberation from the roof as shown at (8). Openings (11) are provided for the insertion of implements. (1,313,834; Aug. 19, 1919.)

Electric Furnace.—JOHN FITZPATRICK and L. T. STEVENS of Niagara Falls, N. Y., produce an efficient muffle type of resistance furnace which is illustrated. The muffle (1) is composed of silicon carbide without bonding material, the walls being about $\frac{1}{2}$ in. in thickness. The resistance mass (2) of granular carbonaceous material surrounds the muffle on all sides but one, electrical contact being made through the graphite electrodes (3). The resistance mass is retained by slabs of silicon carbide (4), (5), (10) and (11). The outside casing is composed of asbestos board or similar

ELECTRIC FURNACE—ABOVE, HORIZONTAL CROSS-SECTION, AND BELOW, VERTICAL CROSS-SECTION

material and the space (14) is packed with heat insulating materials. In operating a small furnace of this type, measuring 6 x 6 x 18 in. with the layer of resistance material 1 in. in thickness around the muffle, a temperature of 1500 deg. C. was attained with a power consumption of 9 kw. at 20 volts. This design of resistance furnace permits of close regulation, the atmosphere being neutral or reducing. (1,313,985, Aug. 26, 1919; assigned to the Carborundum Co.)

Progress in Tanning Fish Leather

Excellent progress in the tanning of fish leather is to be recorded, and a number of the difficulties obstructive to the development of the industry have been overcome by tanners in this field.

One company which is tanning fish skins has established a station in North Carolina and another in Florida for the capture of sharks and porpoises, and is meeting with success in its fishery for sharks. It is understood that the number of stations will be increased as rapidly as possible. Another company has recently acquired a site for a tannery in Washington which plans to tan the hides of sharks, beluga, hair seals, etc.

Samples of leather recently submitted show marked improvement in appearance over earlier samples. The leather is soft and pliable and appears to have ample strength for many uses. Arrangements have been perfected for the Bureau of Standards to make tests of the leather products as to durability, porosity, tensile strength, pliability, water absorption, wearing qualities, etc.

The nets which the Bureau developed for the capture of sharks are proving successful and are being adopted for the fishery. At the fishery stations the liver oil is being extracted and the flesh converted into fertilizer, so that none of the material is wasted.

Refined Potassium Salts in 1918

The statistics of the domestic production of refined potassium salts in 1918 compiled by the United States Geological Survey, Department of the Interior, are now practically complete, and they represent the first attempt at such compilation. The figures are classified in greater detail than heretofore and, except those for a few items and some minor chemicals, are believed to be substantially correct. About 30 different refined potassium salts were produced by 47 firms in 1918. The total production amounted to 53,503,017 lb., valued at \$17,491,414, and the sales amounted to 43,674,844 lb., valued at \$15,634,125. In addition there were produced 62,972,000 lb. of potassium chloride, more or less refined, valued at \$5,749,216, and 13,652,000 lb. of potassium sulphate, valued at \$1,530,499. These two salts were derived from original sources and were used in fertilizers or as raw materials in the production of other refined potassium salts. Table I, compiled by W. B. Hicks, of the Survey, summarizes the production

of all potassium salts except the two last named with as much detail as is consistent with the confidential nature of the individual reports.

The figures show that the production in 1918 was only about half that in 1914, when more than 80,000,000 lb. were produced, but the total value of the output in 1918 was about double that in 1914, for the average price per lb. in 1918 was about four times that in 1914.

EXPORTS

The exports of potassium salts in 1918 were valued at \$1,372,170 and included 696 short tons of potassium chlorate, valued at \$534,491. All other salts were valued at \$837,679. The value of the exports was nearly ten times that in 1914, which amounted to \$132,729. In 1914 muriate constituted the bulk of the exports; in 1918 chlorate made up a large part of them.

Acid-Proof Apron

While aprons made from rubber fabric have been fairly satisfactory in storage battery service stations and other places where the work was light, they have been a failure in acid-pickling works, where they received rough mechanical treatment. With all its inconveniences and cost, however, it has never appeared a sufficiently important matter to any individual manufacturer to devote the necessary amount of research to the proper solution of the problem, practically every concern being satisfied to get along the best it could with whatever kind of so-called rubber aprons they could pick up, and getting what service they could out of them.

The Defiance Welding Co., of Defiance, Ohio, manufacturing automotive equipment of various kinds, including the ordinary automobile wash apron, has been giving a considerable amount of thought and laboratory time to this question, and after repeated failures and near-successes has finally succeeded in producing the Invincible acid apron which, it is claimed, lives up in every way to its name, and which in fact was not given its present name until it had thoroughly proved its merits, not only in the Defiance Welding Co.'s factory, but also in numerous manufacturing plants throughout the country having the most severe acid conditions.

The special fabric which has been developed for use in this apron has an extremely high resistive quality to all acids, giving an unusually long life under the worst conditions, but the fabric is produced in such a way that it can be put on the market at a very reasonable price, comparing favorably with the ordinary rubber apron in price and lasting very much longer.

Obituary

Dr. CYRIL G. HOPKINS, head of the department of agronomy at the University of Illinois, died at Gibraltar on Oct. 6, of malaria. He had finished one year's study of the exhausted soils of Greece and was returning home after completing his official report. He was 53 years of age. He was primarily a chemist and announced the doctrine that "the farmer should first know his soil by an inventory of its constituents, particularly those likely to run short, as a merchant takes frequent inventory of his stock and places timely orders where it is running short and leaving the full shelves alone until they, too, begin to run low." He, therefore, opposed the theory of mixed fertilizers just as he did that of a patent medicine, holding that a proper examination will indicate what is lacking. He also insisted that the farmer should put back into the soil what he took from it.

TABLE I

Production and sale of refined potassium salts in the United States in 1918^a

	Number of Firms	Production		Sale	
		Lb.	Value	Lb.	Value
Acetate	5	93,307	\$60,761	90,229	\$59,314
Aluminum sulphate (alum) ^b	3	10,922,955	275,041	9,699,645	251,181
Bromate, iodate, and perchlorate	3	513,100	245,611	510,699	243,198

Personal

Dr. HAROLD S. ADAMS has been promoted to production manager for Squibbs & Sons, New Brunswick, N. J.

Dr. WILLIAM D. BONNER has returned to Salt Lake City after a summer at Rangely, Colo., where he was operating the Raven Oil & Refining Co.

Mr. LINN BRADLEY, formerly chief engineer for the Research Corporation, administering the Cottrell patents in certain industries, has resigned to engage in consulting practice at 46 South Arlington Ave., East Orange, N. J. He will specialize on apparatus and personal service for the collection of dust and fumes.

Dr. HORACE G. BYERS has accepted the chair of chemistry at Cooper Union, New York City.

Mr. CHARLES A. CHASE, mining and metallurgical engineer, Denver, Colo., recently spent a few days in New York City.

Dr. E. O. ELLINGTON has accepted the chair of chemistry at St. Olaf's College, Northfield, Minn.

Mr. F. B. FOLEY has gone from the Pittsburgh laboratory of the Bureau of Mines to Dr. Howe's laboratory at Bedford Hills, N. Y., in connection with the co-operative investigation on carbon steels there in progress.

Dr. C. C. FOWLER has accepted the position of research chemist for the National Candy Co., Chicago, Ill.

Mr. WALTER H. GARASHA has accepted the managership of the Atlas Laboratory Equipment Bureau, 731 North Wells St., Chicago, Ill.

Mr. HERBERT W. GEPP, general manager of the Electrolytic Zinc Co., Hobart, Tasmania, has been visiting in New York City.

Sir RICHARD GLAZEBROOK has resigned the directorship of the National Physical Laboratory at Teddington, England, which he held since its organization in 1899.

Mr. CARL HELGESON has resigned his position as chemist with Swift & Co. to accept employment with the Liquid Carbonic Co., Chicago, Ill.

Dr. DAVID KLEIN, recently relieved from active duty as Major, U. S. Army, has returned from foreign service to assume the duties of a new position on the faculty of Johns Hopkins University. While serving in Europe he was instrumental in putting the French bakeries on a sanitary basis for the production of bread furnished to the A. E. F., and also held a diplomatic commission with the Herbert Hoover staff in Serbia.

Dr. S. C. LANGDON, department of chemistry, Northwestern University, has added the duties of chemist and bacteriologist of the city of Evanston to his university work. He succeeds Dr. W. LEE LEWIS, resigned.

Mr. E. R. LEIDERER, formerly connected with the Galena Signal Oil Co. and more recently with the Home Oil Refining Co. of Texas, is now connected with the Atlantic Gulf Oil Corporation, 11 Broadway, New York.

Mr. G. M. MCCOLLUGH has resigned as manager of the heavy acid sales department of the Monsanto Chemical Co. He is succeeded by A. B. BRADLEY, who has been with the company for some time.

Mr. A. G. MCGREGOR has returned to Warren, Ariz., after several days in New York City in connection with the work of rebuilding Cerro de Pasco.

Dr. E. P. MATHEWSOON resigned his position Nov. 1 as director of the American Smelting & Refining Co. and the American Smelters Securities Co. and has opened an office at 42 Broadway, New York City, as consulting engineer.

Mr. J. H. NEAD, who during the war served as Captain in the Ordnance Department of the Army in this country and France, has become associated with the American Rolling Mill Co. as metallurgist.

Mr. H. C. PARMELEE addressed the Society of Industrial Engineers at Cleveland on Oct. 31, on "The Effect of European Conditions on American Industry."

Mr. J. H. PERRY, who was associated with Captain Curtis at U. S. N. P. No. 1, Sheffield, Ala., during the war, has returned to Northwestern University, Evanston, Ill., to continue his work with Dr. Curtis.

Dr. R. R. RENSHAW has been placed in charge of chemical engineering courses at the University of Minnesota, Minneapolis, Minn.

Mr. C. H. REPETH visited metallurgical plants in the vicinity of New York the latter part of October.

Mr. GILBERT RIGG, formerly of the New Jersey Zinc Co. and now metallurgist for the Associated Smelters Proprietary, Ltd., Melbourne, Australia, was in New York City recently.

Dr. JAMES K. SENIOR, having been relieved from active duty in the Chemical Warfare Service, has joined the research staff of Procter & Gamble, Cincinnati, Ohio.

Mr. ARTHUR VAN KLEEK has returned from foreign service with the Sanitary Corps, U. S. Army, to accept his old position as chemist with the Western Electric Co., Chicago. He was engaged in water purification work for the A. E. F.

Mr. WILLIAM WRAITH is in the Rocky Mountain region, inspecting properties of the International Smelting Co. and affiliated corporations.

Current Market Reports

The Non-Ferrous Metal Market

Monday, Dec. 1.—A sharp advance in the Eastern price of tin caused a firmer tone in shipments from the Straits for January-February delivery. In November, deliveries into consumption from Atlantic ports amounted to 5600 tons, with stocks and landing on Nov. 30 aggregating 5000 tons. Prime Western zinc is strong at 8.45c. in New York. Copper remains steady, though the feeling has recently improved. Large interests quote 18½c. a pound.

	Cents per Lb.
Aluminum, New York, 98-99% ingots.....	33.00

The Iron and Steel Market

The iron and steel industry is now almost through with its strike and yet the excess of demand over supply, in the market, has increased. There are three reasons. First, stocks in the hands of buyers, both jobbers and manufacturing consumers, are quite largely exhausted. Early in the strike, which started ten weeks ago, they were drawn upon in such manner as to make up in great measure for the curtailment in production caused by the strike. Second, ending of the strike in a given plant or district

does not mean the immediate resumption of normal production, as production grows rather slowly, and the after effects of the strike may last for months, in decreasing intensity. Third, there is the psychological factor. The majority of buyers have become convinced that there is going to be a shortage of steel, hence they magnify their requirements. Last May they were underestimating their requirements by large percentages.

The steel price maintenance policy, which is distinctly a Steel Corporation affair in its inception, though participated in by all or nearly all the large independents, is succeeding by main force where it obtains, but does not prevent the smaller producers who desire to do so from securing premiums for early deliveries. There is nothing like a universal policy. Thus the independent tin plate manufacturers, with scarcely an exception, are rigidly pursuing the policy of selling for the first half of 1920 at the March 21 price of \$7 (per base box, 100-lb.), while on the other hand less than half the independent sheet mills are selling, at least in proportion to their respective capacities, at the March 21 prices for sheets, 4.35c for black, 5.70c for galvanized and 3.55c for blue annealed. Some are holding back, while others are openly quoting premium prices.

PIG IRON ADVANCES

The pig iron market at the moment presents all the appearances of a runaway, for striking an average of all grades and districts it is just now advancing at the rate of a dollar a ton or more a week. The runaway may not last long, however, when there is the restraining influence of steel prices being held, for in such a circumstance the steel making grades at any rate cannot advance indefinitely, and the indications are strongly that pig iron advances will not have the support or encouragement of an advance in Lake Superior iron ore for the 1920 season.

In some districts furnaces are selling for the first half of 1920, while in other districts they claim to be doing no more than disposing of the remainder of their prospective make for the first quarter of the year. For nearby deliveries the foundry iron market is approximately as follows: Delivered Philadelphia, \$37.10; at furnace: Buffalo, \$36; Cleveland, \$37; Chicago, \$33; Birmingham, \$33; valley, \$33 to \$35. Bessemer at valley furnace has sold at \$33 to \$35, while basic has been done at \$32.

CONNELLSVILLE COKE

The Connelssville coke trade has been under the threat for a week that production would be restricted for the release of coal for general consumption, and there has been the further stiffening influence of purchases of prompt furnace coke by consumers whose own production of coke has been curtailed by coal scarcity produced by the strike. Prompt furnace coke has ruled strong at \$6.25 in the past week, against an average of about \$3.70 last April, the low month of the year.

Furnace coke contracts for the first half or all of next year have been under negotiation. Operators have claimed a large prospective increase in the cost of production on the ground that the bituminous coal mining scale for the central competitive field was about to experience a large advance, and the Connelssville coke operators would have to advance their mining rates in proportion, also advancing their coke oven labor. The situation now, however, is that Dr. Garfield has prescribed that there must be an advance in the mining scale of 14 per cent, no more and no less, and in the circumstances no large advance in Connelssville coke prices can be predicted upon wages. How this will affect negotiations on furnace coke contracts remains to be seen. The strategic position of coke operators is further weakened by the pronouncement that coal must be held at \$2.35. This would mean a value of about \$3.50 for the coal required to make a ton of coke, and \$6 or \$6.50 for coke, as operators have demanded, would seem out of line. Negotiations have just been concluded on two or three contracts on a ratio basis, 5 to 1 against basic pig iron, valley. At the present \$32 market this would mean \$6.40 for the coke. The brand involved in this case, however, is a particularly desirable one.

The Chemical Market

New York, November 30, 1919.

The shortage of basic materials, which grows more pronounced as the year draws to a close, causes manufacturers to be reluctant about giving estimates, although inquiries are increasing. It is interesting to note that several coal-tar producers are undertaking contracts for 1920, on such standard items as aniline oil and salts. The business of disposing of resale lots has made a quiet market for vegetable oils.

NAVAL STORES

In the naval stores field, rosins on spot are very scarce, E, F, G and H grades being unobtainable. While supplies of rosins are arriving regularly they are needed to fill back deliveries. Inquiries on the medium grades have picked up recently for both domestic and export, the latter interest emanating from Scandinavia, Japan and South America. There are, however, few inquiries for spirits of turpentine, of which it is possible to obtain small lots on spot. The activity in paraffine waxes continues to compensate for the sluggishness of the other waxes. TN and orange, superfine, are practically the only grades of shellac on which dealers are quoting. Due to continued scarcity of supplies and large buying orders from England and the United States the primary market is appreciably higher. Domestic users are not deterred by this situation and there seems to be no limit to the price they will pay for the raw material.

Although during the month there has been considerable buying of crude rubber for January-June and nearby deliveries, the past week has called forth little interest. As is the custom, manufacturers will probably wait until the close of the automobile show and begin their purchasing in January.

The market in England and the Far East is likewise reported easier.

HEAVY CHEMICALS

Sodium bichromate continues to ascend, the minimum figure at this writing being 15½c per lb., and with it goes *formaldehyde*, dealers quoting from 32-35c per lb. Although speculation has played an important part in sending the price of formaldehyde up to the present record level, there is at the same time a stringency on the production end. This is evinced by the statement of an important manufacturer, that owing to the scarcity of basic materials and labor uncertainties he is offering no quotations for deliveries in the next year.

The *caustic soda* market is now controlled by manufacturers. The price of the 76 per cent grade was 4 per cent for export on Tuesday by leading sellers. This makes the export quotation \$3.50 per cwt., less 1 per cent, as against \$3.50, less 5 per cent, which has hitherto prevailed. All indications point to higher prices on this commodity during the coming year.

Sodium prussiate, yellow, which for some time has been in a weak position, appears to be coming into its own again, with present quotations holding firm at 23-24c per lb.

Four hundred tons of *sodium nitrite* arrived on one steamer during the week, and with this addition to present stocks the market is easier at the 14c per lb. quotation. Orders for future deliveries are being taken at 12½-13½c per lb.

As has been the case for the past two weeks, there is practically no spot *ammonium sulphate* to be obtained on the market. As high as \$5.90 per cwt. is being paid for deliveries during the last six months of 1920.

Although practically sold up on their output of *Glauber's salt* for the next three months, manufacturers are open for a few more contracts. On *lithopone* they are sold up for the same period. The price on lithopone during the last quarter of 1920 is expected to be around 8 or 9c per lb. The price for the first quarter is given at 7-7½c. One manufacturer is holding the contract price on *Glauber's salt* at \$1.15 per cwt. in bags, and \$1.25 in barrels, while another is shading these figures to \$1.10 in bags and \$1.15 in barrels.

Amyl acetate.....gal.	10 - 11	11 - 12
Arsenic, oxide, lump (white arsenic).....lb.	23 - 24	25 - 30
Arsenic, sulphide, powdered (red arsenic).....lb.	85.00	90.00 - 100.00
Barium chloride.....ton	10 - 10 1/2	11 - 12
Barium dioxide (peroxide).....lb.	03 - 03 1/2	04 - 04 1/2
Barium nitrate.....lb.	03 - 03 1/2	04 - 04 1/2
Barium sulphate (precip.) (blanc fixe).....lb.	03 - 03 1/2	04 - 04 1/2
Bleaching powder (see calcium hypochlorite).....lb.		
Brae Vitrol (see copper sulphate).....lb.		
Borax (see sodium borate).....lb.		
Bromine.....lb.	2.00 - 2.05	2.05 - 2.10
Bromine.....lb.	2.00 - 2.05	2.05 - 2.10
Calcium carbide.....lb.	04 - 05	05 - 06
Calcium chloride, fused, lump.....ton	19.00 - 25.00	30.00 - 40.00
Calcium chloride, granulated.....lb.	01 1/2 - 01 1/2	02 - 02 1/2
Calcium hypochlorite (bleaching powder).....cwt.	2.25 - 2.50	2.50 - 3.00
Calcium peroxide.....lb.	1.50 - 1.70	1.70 - 2.00
Calcium phosphate, monobasic.....lb.	75 - 80	80 - 90
Calcium sulphate, precipitated.....lb.	06 - 09	09 - 10
Carbon bisulphide.....lb.	10 - 11	12 - 14
Carbon tetrachloride, drums.....lb.	10 - 11	12 - 14
Carbonyl chloride (phosgene).....lb.	75 - 80	80 - 90
Caustic potash (see potassium hydroxide).....lb.		
Caustic soda (see sodium hydroxide).....lb.		
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	05 - 05 1/2	06 - 06 1/2
Cobalt oxide.....lb.	1.50 - 1.55	1.55 - 1.60
Copperas (see iron sulphate).....lb.		
Copper carbonate, green precipitate.....lb.	28 - 31	31 - 35
Copper cyanide.....lb.	65 - 70	70 - 80
Copper sulphate, crystals.....lb.	08 1/2 - 08 3/4	09 - 09 1/2
Cream of tartar (see potassium bitartrate).....lb.		
Crotonal salt (see sodium sulphate).....lb.	19 - 33	33 - 40
Formaldehyde, 40 per cent.....lb.	20 - 21	21 - 22
Glauber's salt (see sodium sulphate).....lb.	4.50	4.50
Glycerine.....lb.	4.50	4.50
Iodine, resublimed.....lb.	4.50	4.50
Iron oxide, red.....cwt.	1.25	1.35
Iron sulphate, (copperas).....cwt.	1.25	1.35
Lead acetate, normal.....lb.	1.35 - 1.50	1.50 - 1.60
Lead arsenate (paste).....lb.	12 - 14	14 - 15
Lead nitrate, crystals.....lb.	85 - 86 1/2	86 1/2 - 90
Litharge.....lb.	09 - 10	10 - 11
Lithium Carbonate.....lb.	13 - 14	14 - 15
Magnesium carbonate, technical.....lb.	2.00 - 2.63	2.63 - 3.00
Magnesium sulphate, U. S. P. 100 lb.	1.75	2.00 - 2.50
Magnesium sulphate, commercial.....lb.	1.75	2.00 - 2.50
Nickel salt, double.....lb.	12 - 15	15 - 16
Nickel salt, single.....lb.	12 - 15	15 - 16
Phosgene (see carbonyl chloride).....lb.		
Phosphorus, red.....lb.	60 - 70	70 - 80
Phosphorus, yellow.....lb.	35 - 37	37 - 40
Potassium bichromate.....lb.	26 1/2 - 27	28 - 28 1/2
Potassium bitartrate (cream of Tartar).....lb.	55 - 60	60 - 65
Potassium bromide, granular.....lb.	74 - 75	75 - 80
Potassium carbonate, U. S. P. 100 lb.	55 - 60	60 - 65
Potassium carbonate, crude.....lb.	23 - 27	27 - 30
Potassium chlorate, crystals.....lb.	18 - 20	21 - 22
Potassium cyanide, 98-99 per cent.....lb.	nominal	30 - 31
Potassium hydroxide (caustic potash).....lb.	25 - 28	35 - 36
Potassium iodide.....lb.	19 - 21	21 - 22
Potassium nitrate.....lb.	19 - 21	21 - 22
Potassium permanganate.....lb.	51 - 56	56 - 60
Potassium prussiate, red.....lb.	1.05 - 1.15	1.15 - 1.20

	Carlots	Less Carlots
Potassium prussiate, yellow.....lb.		40 - 44
Potassium sulphate.....ton	225.00	
Rochelle salts (see sodium potas. tartrate).....ton	17.00 - 21.00	
Sal ammoniac (see ammonium chloride).....lb.		1.19
Salt cake (sodium sulphate).....ton	17.00 - 21.00	
Silver cyanide.....oz.		80 - 81 1/2
Silver nitrate.....lb.	1.85 - 2.05	2.10 - 2.50
Soda ash, light.....100 lb.	2.15 - 2.30	2.30 - 2.50
Soda ash, heavy.....100 lb.	06 1/2 - 07	07 1/2 - 08
Sodium acetate.....100 lb.	2.35 - 2.50	2.75 - 3.00
Sodium bicarbonate.....lb.	1.15 - 1.20	1.20 - 1.25
Sodium bisulphate, (extra cake).....ton	3.00 - 8.00	10.00 - 11.00
Sodium bisulphate.....cwt.	1.80 - 1.90	2.00 - 2.10
Sodium borate (borax).....lb.	07 1/2 - 08	08 - 08 1/2
Sodium carbonate (all soda).....100 lb.	1.35 - 1.50	1.50 - 1.75
Sodium chloride.....lb.	12 - 13	13 - 14
Sodium cyanide, 98-99 per cent.....lb.	30 - 31	31 - 34
Sodium fluoride.....lb.	15 - 16	16 - 17
Sodium hydroxide (caustic soda).....100 lb.	3.35 - 3.40	3.45 - 3.50
Sodium hydroxide.....lb.	2.50 - 3.25	3.25 - 3.50
Sodium nitrate.....100 lb.	2.87 1/2 - 3.25	3.75 - 4.00
Sodium nitrite.....lb.	14 - 15	15 - 16
Sodium peroxide, powdered.....lb.	03 1/2 - 04	04 1/2 - 05
Sodium phosphates, dibasic.....lb.		41 - 44
Sodium potassium tartrate (Rochelle salts).....lb.		23 - 25
Sodium prussiate, yellow.....lb.		26 - 27
Sodium silicate, solution (40 deg.).....lb.	02 - 03	03 1/2 - 04 1/2
Sodium silicate, solution (60 deg.).....lb.	02 1/2 - 03	03 1/2 - 04 1/2
Sodium sulphate, crystals (Glauber's salt) cwt.	1.15 - 1.25	1.50 - 2.00
Sodium sulphide, crystal, 60-62 per cent. (cone).....lb.		05 - 06
Sodium sulphite.....lb.	03 1/2 - 04	04 - 06
Strontium nitrate, crystals.....lb.	25 - 28	28 - 30
Sulphur chloride.....lb.	05 1/2 - 06	06 - 07
Sulphur, crude.....lb.	22.00	22.00
Sulphur dioxide, liquid-cylinders.....lb.		10 - 12
Sulphur (sublimed), flour.....100 lb.	3.10 - 3.40	3.40 - 3.65
Sulphur, roll (brimstone).....100 lb.	2.95 - 3.15	3.15 - 3.40
Tin bichloride (stannous).....lb.	44 - 50	50 - 55
Tin oxide.....lb.	60 - 65	65 - 70
Zinc carbonate, precipitate.....lb.	20 - 22	22 - 24
Zinc chloride, gran.....lb.	13 1/2 - 14	14 - 15
Zinc cyanide.....lb.	18 - 19	19 - 20
Zinc dust.....lb.	09 - 11	11 - 12
Zinc oxide, dry American.....lb.	03 1/2 - 04	04 - 04 1/2
Zinc sulphate.....lb.	03 1/2 - 04	04 - 04 1/2

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....lb.	\$1.00 - \$1.10
Alpha naphthol, refined.....lb.	1.40 - 1.50
Alpha naphthylamine.....lb.	35 - 38
Aniline oil, drums extra.....lb.	36 - 42
Aniline salt.....lb.	90 - 1.00
Anthracene, 80% in drums (100 lb.).....lb.	1.00 - 1.15
Benzaldehyde (f.f.c.).....lb.	1.10 - 1.25
Benzidine, base.....lb.	1.24 - 1.35
Benzidine, sulphate.....lb.	95 - 110
Benzoic acid, U. S. P. lb.	90 - 1.00
Benzoate of soda, U. S. P. gal.	80 - 1.00
Benzol, pure, water-white, drums (100 lb.).....gal.	24 - 28
Benzol, 90% in drums (100 lb.).....gal.	24 - 28
Benzyl chloride, 95-97% refined.....lb.	35 - 40
Benzyl chloride, tech.....lb.	25 - 35
Beta naphthylamine.....lb.	4.50 - 5.00
Beta naphthol, sublimed.....lb.	75 - 80
Beta naphthol, tech.....lb.	47 - 55
Beta naphthylamine, sublimed.....lb.	2.25 - 2.35
Benzol, U. S. P. 80% in drums (100 lb.).....lb.	18 - 25
Ortho-cresol, drums (100 lb.).....lb.	23 - 25
Creosylic acid, 92-99% straw color, in drums.....gal.	80 - 85
Creosylic acid, 95-97% dark, in drums.....gal.	85 - 90
Creosylic acid, 50% first quality, drums.....lb.	06 - 07
Dichlorobenzol.....lb.	1.07 - 1.25
Diethylamine.....lb.	57 - 60
Dimethylamine.....lb.	27 - 32
Dinitrobenzol.....lb.	25 - 30
Dinitronaphthalene.....lb.	45 - 55
Dinitrophenol.....lb.	27 - 35
Dinitrotoluenol.....lb.	38 - 45
Dip oil, 25% tar acids, car lots, in drums.....gal.	38 - 65
Diphenylamine.....lb.	155 - 170
H-acid.....lb.	12 - 15
Metaphenylenediamine.....lb.	1.10 - 1.25
Monochlorobenzol.....lb.	1.12 - 1.15
Mononitrobenzylamine.....lb.	1.50 - 1.75
Naphthalene crushed, in bbls. (250 lb.).....lb.	06 - 07 1/2
Naphthalene, flakes, heavy, in drums.....lb.	08 1/2 - 10
Naphthalene, balls.....lb.	75 - 125
Naphthionic acid, crude.....lb.	19 - 25
Nitrobenzol.....lb.	35 - 45
Nitro-naphthalene.....lb.	12 - 15
Nitro-toluenol.....lb.	30 - 40
Ortho-amidophenol.....lb.	3.75 - 4.25
Ortho-dichlorobenzol.....lb.	20 - 25
Ortho-nitrophenol.....lb.	30 - 35
Ortho-nitro-toluenol.....lb.	25 - 40
Ortho-toluidine.....lb.	25 - 30
Para-amidophenol.....lb.	2.75 - 3.50
Para-nitrophenol, HCl.....lb.	2.75 - 3.25
Para-dichlorobenzol.....lb.	15 - 18
Paranitraniline.....lb.	1.10 - 1.20
Para-nitro-toluenol.....lb.	1.35 - 1.50
Paraphenylenediamine.....lb.	2.50 - 3.00
Paratoluidine.....lb.	2.00 - 2.25
Phthalic anhydride.....lb.	1.18 - 1.50
Phenol, U. S. P. drums (dest.), (240 lb.).....gal.	3.50 - 3.75
Pyridine.....lb.	6.50 - 6.75
Resorcin, technical.....lb.	55 - 60
Resorcin, pure.....lb.	90 - 95
Salicylic acid, tech., in bbls. (110 lb.).....lb.	20 - 27
Salicylic acid, U. S. P. lb.	18 - 22
Salol.....lb.	26 - 30
Solvent naphtha, water-white, in drums, 100 gal. gal.	
Solvent naphtha, water-white, in drums, 100 gal. gal.	
Sulphanilic acid, crude.....lb.	26 - 30

Tollidine	lb.	\$1 70	—	\$2 50
Tollidine, mixed	lb.	45	—	55
Toluol, in tank cars	gal.	27	—	30
Toluol, in drums	gal.	28	—	30
Nylinde, drums, 100 gal.	lb.	44	—	50
Nylinde, pure, in drums	gal.	37	—	40
Nylinde, pure, in tank cars	gal.	35	—	40
Nylinde, commercial, in drums, 100 gal.	gal.	21	—	27
Nylinde, commercial, in tank cars	gal.	22	—	27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	\$0.41	—	\$0.43
Beeswax, refined, yellow	lb.	48	—	51
Beeswax, white pure	lb.	65	—	68
Carabaua, No. 1	lb.	84	—	86
Carabaua, No. 2, regular	lb.	75	—	78
Carabaua, No. 3, North Country	lb.	46	—	47
Japan	lb.	191	—	20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	06	—	06
Paraffine waxes, crude, scale 124-126 m.p.	lb.	06	—	07
Paraffine waxes, refined, 118-120 m.p.	lb.	09	—	09
Paraffine waxes, refined, 128-130 m.p.	lb.	09	—	09
Paraffine waxes, refined, 133-135 m.p.	lb.	11	—	11
Paraffine waxes, refined, 135-137 m.p.	lb.	12	—	13
Stearic acid, single pressed	lb.	28	—	26
Stearic acid, double pressed	lb.	28	—	29
Stearic acid, triple pressed	lb.	32	—	33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940	gal.	\$1 10		
Pine oil, pure, dest. dist.	gal.	96		
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	45		
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	65		
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	09		
Pine tar, ref., thin, sp. gr. 1.080-1.090	gal.	88		
Turpentine, crude, sp. gr. 0.900-0.970	gal.	35		
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990	gal.	30		
Pine wood creosote, ref.	gal.	48		

Naval Stores

The following prices are f.o.b., New York, for carload lots

Rosin B-D, bbl.	280 lb.	\$17.25	—	\$17.65
Rosin E-F, do.	280 lb.	17.25	—	17.65
Rosin K-N, do.	280 lb.	19.75	—	22.25
Rosin W-G-W, do.	280 lb.	22.50	—	24.00
Wood rosin, bbl.	280 lb.	17.00	—	17.50
Spirit of turpentine	gal.	1.68	—	1.70
Wood turpentine, steam dist.	gal.	1.50	—	1.50
Wood turpentine, dest. dist.	gal.	1.48	—	1.50
Pine tar pitch, bbl.	200 lb.	8.25	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	14.75
Retort tar, bbl.	280 lb.	15.00	—	15.00
Rosin oil, first run	gal.	86	—	91
Rosin oil, second run	gal.	86	—	91
Rosin oil, third run	gal.	1.10	—	1.10
Rosin oil, fourth run	gal.	1.05	—	1.15

Solvents

72-76 deg., steel bbls. (85 lb.)	gal.	\$0.331		
70-72 deg., steel bbls. (85 lb.)	gal.	319		
68-70 deg., steel bbls. (85 lb.)	gal.	304		
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	231		

Crude Rubber

Para—Upriver fine	lb.	\$0.491	—	\$0.491
Upriver coarse	lb.	341	—	351
Upriver caucho ball	lb.	341	—	351
Plantation—First latex crepe	lb.	52	—	53
Ribbed smoked sheet	lb.	46	—	47
Brown crepe, thin, clean	lb.	46	—	47
Amber crepe No. 1	lb.	50	—	51

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls.	lb.	\$0.181	—	\$0.19
Castor oil, AA, in bbls.	lb.	211	—	22
China wood oil, in bbls.	lb.	221	—	23
Cocunut oil, Ceylon grade, in bbls.	lb.	181	—	18
Cocunut oil, Ceylon grade, in bbls.	lb.	191	—	19
Corn oil, crude, in bbls.	lb.	18	—	18
Cottonseed oil, crude (f.o.b. mill)	lb.	181	—	181
Cottonseed oil, sunflower	lb.	173	—	173
Cottonseed oil, winter yellow	lb.	241	—	25
Linseed oil, raw, car lots	gal.	1.77	—	1.77
Linseed oil, raw, tank cars	gal.	1.72	—	1.72
Linseed oil, boiled, car lots	gal.	1.79	—	1.79
Linseed oil, commercial	gal.	2.50	—	2.80
Palm, Lagos	lb.	17	—	17
Palm, bright red	lb.	161	—	171
Peanut, Niger	lb.	17	—	17
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	231	—	231
Peanut oil, refined, in bbls.	lb.	261	—	27
Rapeseed oil, refined in bbls.	gal.	1.45	—	1.50
Rapeseed oil, boiled, in bbls.	gal.	1.60	—	1.60
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	173	—	181
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	151	—	151

FISH

Winter pressed Menhaden	gal.	\$1.20	—	
Yellow bleached Menhaden	gal.	1.25	—	
White bleached Menhaden	gal.	1.25	—	
Blown Menhaden	gal.	1.30	—	

Miscellaneous Materials

All Prices f.o.b., N. Y.

Sarytes, domestic, white, flatted	ton	\$35 00	—	\$40 00
Sarytes, of color	ton	20 00	—	23 00
Blanc fixe, dry	lb.	071	—	043
Blanc fixe, pulp	ton	47 50	—	50 00
Chalk, English, extra light	lb.	05	—	07
Chalk, English, light	lb.	041	—	06

Chalk, English, dense	lb.	5 04	—	5 05
China clay (Kaolin), imported, lump	ton	25 00	—	35 00
China clay (Kaolin), imported, powdered	ton	10 00	—	60 00
China clay (Kaolin), domestic, lump	ton	10 00	—	20 00
China clay (Kaolin), domestic, powdered	ton	25 00	—	40 00
Feldspar	ton	13 50	—	17 00
Fluorspar, acid grade, lump, f.o.b. mines	net ton	30 00	—	35 00
Fluorspar, acid grade, ground, f.o.b. mines	net ton	35 00	—	45 00
Fuller's earth, domestic, powdered	ton	25 00	—	30 00
Fuller's earth, imported, powdered	ton	35 00	—	40 00
Pumice stone, imported	lb.	03	—	06
Pumice stone, domestic	lb.	021	—	
Shellac, T.N.	lb.	1 10	—	1 15
Shellac, D. C.	lb.		—	
Shellac, V. S. C.	lb.		—	
Shellac, Diamond 1	lb.		—	
Shellac, orange, fine	lb.	1 25	—	
Shellac, orange, superfine	lb.	1 20	—	1 30
Shellac, A. C. granet	lb.	1 10	—	
Shellac, bleached, bone dry	lb.	1 35	—	
Shellac, bleached, fresh ground	lb.	1 10	—	1 15
Sonpetone	ton	16 00	—	25 00
Talc, domestic	ton	60 00	—	60 00
Talc, imported	ton	60 00	—	70 00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	80-90 at Chester, Penn.		
Chrome cement	net ton	45-50 at Chester, Penn.		
Clay brick, lat quality fireclay	1,000	45-45 at Clearfield, Penn.		
Clay brick, 2nd quality	1,000	30-35 at Clearfield, Penn.		
Magnesite, best burned	net ton	55-55 at Chester, Penn.		
Magnesite brick, 9 x 4 1/2 x 2 1/2 in.	net ton	40-50 at Chester, Penn.		
Silica brick	1,000	41-45 at Mt. Union, Penn.		

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	\$200 00	—	\$250 00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	25	—	40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	70	—	
Ferro-manganese, 70-80% Mn.	gross ton	110 00	—	115 00
Spiegelstein, 16-20% Mn.	gross ton	33 00	—	36 00
Ferro-manganese, per lb. of Mn.	lb.	2 50	—	3 00
Ferro-silicon, 50-60% Si.	gross ton	80 00	—	95 00
Ferro-silicon, 75% Si.	gross ton	150 00	—	175 00
Ferro-silicon, 10-15% Si.	gross ton	45 00	—	60 00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	1 25	—	1 40
Ferro-uranium, 35-40%, of U.	lb.	7 00	—	
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	5 50	—	7 00

Ores and Semi-finished Products

Chrome ore, 35-40% Cr ₂ O ₃	unit	\$0 60	—	\$0 80
Chrome ore, 48% and over	unit	90	—	1 00
Coke, foundry, f.o.b. ovens	net ton	7 00	—	7 50
Coke, furnace, f.o.b. ovens	net ton	6 00	—	6 50
Petroleum coke, refinery, Atlantic seaboard	net ton	12 00	—	12 50
Fluorspar, gravel, f.o.b. mines	net ton		—	25 00
Manganese ore, 45% Mn and over	unit	50	—	75
Manganese ore, chemical (MnO ₂)	gross ton	60 00	—	70 00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂	lb.	75	—	85
Tungsten, Scheelite, 60% WO ₃ and over, per unit of WO ₃	unit	9 00	—	15 00
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃	unit	7 50	—	10 00
Uranium oxide, 96%	lb.	2 75	—	3 00
Vanadium pentoxide, 99%	lb.	6 00	—	
Pyrites, foreign, lump	unit	17	—	
Pyrites, foreign, fine	unit	17	—

BUILDING MATERIALS

Portland cement, at dock, without bags	bbl.	\$2 80		
Lump lime, common, including container	300 bbl.	2 65		
Common brick, at dock	lb.	60 00		
Yellow pine, 3x4 to 8x8, 20 ft. and under	lf.	50 00		
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago	lf.	50 00		
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis	lf.	40 00		
Roofings, tar felt (14 lb. per 100 sq ft.)	ton	70 00		
Roofings, tar pitch (in 400-lb. bbl.) carlots	ton	21 00		
Roofings, asphalt felt carlots	ton	63 00		
Roofings, asphalt felt carlots	ton	2 25		
Roofings, slate-surfaced, per roll of 108 sq ft. carlots	ton	6 00		
Linseed oil, raw in barrels	gal.	1 75		
Linseed oil, 5 gal. cans	gal.	1 90		
Red lead, dry, 100 lb. keg	lb.	11		
Red lead, in oil, 100 lb. keg	lb.	14		
Red lead, dry, 5 lb. cans	lb.	11		
Red lead, in oil, 5 lb. cans	lb.	16		
White lead, dry and in oil, 100 lb. keg	lb.	13		
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	11		
White lead, dry and in oil, 5 lb. cans	lb.	15		

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in	100 lb.	\$2 45		
Angles, 3 to 6-in, 4-in. thick	100 lb.	2 45		
Truss, 3-in and larger	100 lb.	2 45		
Plates	100 lb.	4 20		
Rivets, structural, 1-in and larger	100 lb.	4 20		
Rivets, conchard for boilers, 1-in and larger	100 lb.	4 30		
Sheet, No. 28 black	100 lb.	4 35		
Sheet, No. 10 blue annealed	100 lb.	5 70		
Sheet, No. 22 galvanized	100 lb.	5 70		

For painted corrugated sheets, add 30c per 100 lb. for 25 x 25 and 25c for 19 to 24 gage; for galvanized corrugated sheets, add 15c, all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

NOTE—These items were compiled as of Nov. 25, but appear in this issue due to the delay in publication due to the printers' strike.

Alabama

FAIRFAX—The Fairfax Mills plant to build a 75 x 163-ft. bleachery. J. E. Sirrine, Gillsville, S. C., engineer.

Arizona

AOJ—The New Cornelia Copper Co. plans to build a 10,000-ton flotation and smelter plant to treat its sulphide ore body. John G. Greenway, general manager.

PHOENIX—Hiram Phillips, engineer, 801 International Life Bldg., will receive bids in December for the construction of a complete "gravity infiltration system." Project includes the erection of a 21 x 400-ft. reservoir, etc. The company will be in the market for extensive pressure reducing apparatus. Estimated cost, \$2,000,000.

Arkansas

ARKANSAS CITY—G. A. Shryock, 306 East Douglas Ave., Wichita, Kans., has awarded the contract for the construction of a 1-story gasoline extraction plant, to Westinghouse, Church, Kerr, Inc., 37 Wall St., New York City. Estimated cost, \$60,000.

Colorado

FT. COLLINS—The Agricultural College here is planning a building for the construction of a 3-story, 52 x 100-ft. physics building, to Edward Reavill, 1435 Vine St., Denver. Estimated cost, \$93,533. Noted Oct. 15.

Connecticut

BRIDGEPORT—The Bridgeport Brass Co., Grand St., has awarded the contract for the construction of a 1-story, 150 x 220-ft. castings shop on Grand St. to Levering & Garrigues Co., 552 West 23rd St., New York City. Estimated cost, \$150,000. Noted Sept. 1.

MIDDLETOWN—The Trustees of Wesleyan University, 374 High St., will receive bids until Dec. 1 for the construction of a 2-story, 100 x 157-ft. laboratory on the campus. Estimated cost, \$300,000. Henry Bacon, 101 Park Ave., New York City, architect. Noted July 1.

OAKVILLE—The Oakville Co., manufacturer of brass goods, has awarded the contract for the construction of a 1-story, 44 x 56-ft. steaming building on Oakville St., to Fred T. Ley & Co., Inc., 499 Main St., Springfield, Mass. Estimated cost, \$30,000.

Idaho

BUHL—The city is having preliminary plans prepared for the construction of a waterworks system. Estimated cost, \$10,000. H. E. Lindon, 593 Market St., San Francisco, engineer.

Illinois

CHICAGO—The Fitzsimons Steel & Iron Co., West 37th St. and Racine Ave., has purchased a site at 33rd St. and Kedzie Ave., and plans to build a modern 1-story plant for the manufacture of cold-drawn steel shapes. Estimated cost, \$300,000.

CHICAGO—The Northwestern Terra Cotta Co., 2525 Claybourne Ave., has awarded the contract for the construction of a plant, consisting of 4 buildings, one 1-story, 240 x 325 ft., one 3-story, 84 x 325 ft., one 1-story, 145 x 155 ft., and one 1-story, 48 x 28 ft., on Claybourne Ave., near Western Ave., to Gerhardt F. Meyne, 127 North Dearborn St. Estimated cost, \$225,000.

Iowa

DES MOINES—Frank Jeffries, city clerk, will soon award the contract for the construction of the Waveland Park sanitary sewer, small septic tank, and filter bed. Estimated cost, \$25,000. K. C. Kastberg, city engineer.

POCAHONTAS—The city has awarded the contract for the construction of a disposal plant in connection with the proposed soda ash plant, consisting of 3 buildings. Estimated cost, \$21,900. Noted Sept. 1.

Kansas

HUTCHINSON—The Solvay Process, Milton Ave., Syracuse, N. Y., is having plans prepared for the construction of a soda ash plant, consisting of 3 buildings. Estimated cost, \$750,000.

NEADESHA—The Standard Oil Co. of Kansas will soon award the contract for the construction of a refinery to consist of 40 additional stills, additional tanks with a capacity of 300,000 bbl., etc.

Kentucky

ASHLAND—The Board of Water Commissioners has awarded the contract for the construction of a 2,000,000-gal. filtration plant, etc. to Joseph E. Nelson & Sons, 117 North La Salle St., Chicago, Ill. Noted July 15.

Maryland

BALTIMORE—The Kaufman Beef Co., 6th St. and Union Stock Yards, is having plans prepared for the construction of a 3-story, 150 x 150-ft. packing house. Estimated cost, \$150,000. C. H. A. Wannenwetsch, William St., Buffalo, N. Y., architect.

CURTIS BAY (Baltimore P. O.)—The Armour Fertilizer Co., 1501 Munsey Bldg., Baltimore, has purchased a 20-acre site here, and plans to construct a fertilizer plant on same. Estimated cost, \$2,000,000.

CURTIS BAY (Baltimore P. O.)—The Standard Guano Co., 1214 Continental Bldg., Baltimore, will soon award the contract for the construction of an acid plant, consisting of four or five 1-story buildings and a 40 x 200 ft. pier, on Aspen St. and Pennington Ave., here. Estimated cost, \$300,000. W. W. Pagon, Lexington Bldg., Baltimore, engineer.

FLKTON—The Town Commissioners plan to install a filtration plant and sewerage system, also enlarge the water mains. Bonds amounting to \$80,000 will be issued for this project. L. J. Houston, Jr., 608 Parkwyth Ave., Baltimore, Md., and Fredricksburg, Va., engineer.

Massachusetts

CHICOPEE FALLS—The Fisk Rubber Co. has awarded the contract for the construction of a 1-story, 23 x 115-ft. factory addition and a 2 x 40-ft. electrical substation addition at its plant, here, to F. T. Ley & Co., Inc., 499 Main St., Springfield. Estimated cost, \$30,000.

FITCHBURG—Crocker, Burbank & Co., Inc., 545 Westminster St., manufacturer of paper, has awarded the contract for the construction of a 2-story, 60 x 200-ft. factory on Westminster St., to Foss & Jenes, 75 Laurel St. Estimated cost, \$100,000. Noted July 1.

MILLBURY—The City of Worcester plans to construct a sewage disposal plant here. Estimated cost, \$250,000. Address Engineering Department, Worcester.

NEW BEDFORD—The New England Refining Co., Boston, has awarded the contract for the construction of a refinery on Harbor St., to F. T. Ley & Co., Inc., 499 Main St., Springfield. Estimated cost, \$250,000.

NORTHAMPTON—Smith College plans to construct a physics and geology building on the college grounds. Estimated cost, \$150,000. W. A. Neilson, president.

WOBBURN—The Buckman Tanning Co. is having preliminary plans prepared for a reinforced-concrete sewage disposal tank and reclamation of tannery sludge. Estimated cost, \$15,000. Vaughn & Meyer, Security Bldg., Milwaukee, engineer.

Michigan

BATTLE CREEK—The Battle Creek Paper Co. has awarded the contract for the construction of a 3-story, 110 x 216-ft. addition to its paper factory at 81 Garrison St., to Witherspoon & Englar, 53 West Jackson Blvd., Chicago, Ill. Estimated cost, \$175,000.

DETROIT—The Detroit Grey Iron Foundry Co. will soon award the contract for the construction of a 2-story, 135 x 150-ft. foundry addition on Wight St. Mildner & Eissen, 924 Hammond Bldg., architect.

DETROIT—The Detroit Lubricator Co., Marquette Ave., has awarded the contract for the construction of a 3-story, 90 x 124-ft. factory, on Marquette and Trumbull Aves., to Walbridge-Aldinger Co., 2356 Penobscot Bldg.

DETROIT—A. J. Detlaft, 121 Lafayette St., E., plans to construct 1 and 2-story foundries and a machine shop on Grand River Ave. and the Terminal Railway. Architect not selected.

DETROIT—The Western Gear Manufacturing Co., 1040 Scotten Ave., is having plans prepared for the construction of a 1-story, 40 x 80-ft. heating plant on Scotten Ave. Cyanide Tanks and equipment will be installed in same. Estimated cost, \$30,000. Louis Seisner, 225 Farwell Bldg., architect and engineer.

LANSING—The city has engaged Alvord & Burdick, engineering firm, 40 Washington Arcade, Detroit, to prepare report on tentative plans and submit estimates for the proposed filtration plant.

MARYSVILLE—The city engaged Smith, Hinchman & Grylls, Engineers, 40 Washington Arcade, Detroit, to prepare plans for the construction of a complete sewerage system on Huron Blvd., and other streets, for a townsite to be planned for 100,000 inhabitants, to include a sewerage treatment works, trunk sewers and laterals, and probably a battery of Imhoff tanks.

MARYSVILLE—The Pressed Metals of Canada, 112 Adelaide St., Toronto, Ont., has awarded the contract for the construction of a 2-story, 72 x 516-ft. brass foundry, along the St. Clair River, to the Witherspoon & Englar Co., 53 West Jackson Blvd., Chicago, Ill. Estimated cost, \$95,000. Noted Sept. 23.

MARYSVILLE—The Wills-Lee Co., Book Bldg., Detroit, has awarded the contract for the construction of a 1-story, 72 x 370-ft. cyanide treatment building on Huron Rd., to the Walbridge-Aldinger Co., 2356 Penobscot Bldg., Detroit.

PONTIAC—The city engaged C. W. Hunsell, engineer, 3048 Penobscot Bldg., Detroit, to prepare plans for water filtration plant at site on Walnut St., to treat lake water for additional supply. Sand filter having capacity of 10,000,000 gal. per day will be designed.

Minnesota

ADRIAN—The city has awarded the contract for the construction of a sewerage system, septic tank, sludge bed and accessories, to Kircher Brothers, Olivia, at \$45,750. Noted Sept. 25.

AUSTIN—The Board of Education has awarded the contract for the construction of a 3-story, 230 x 300-ft. high school, to the Madison Construction Co., Builders' Exchange, Minneapolis. A chemical laboratory will be installed in same. Estimated cost, \$150,000.

AUSTIN—The Board of Education will soon award the contract for the installation of a water softening system in the proposed school. Estimated cost, \$32,000. Frank Tustison, Auditorium, Minneapolis, engineer.

FOLEY—The city has awarded the contract for the construction of a sewerage system and disposal plant, to the Pastorek Construction Co., 308 Lyceum Bldg., Duluth. Noted Sept. 14.

ST. PAUL—The St. Paul Welding Co., 173 West 3rd St., has awarded the contract for the construction of a 2-story, 36 x 75-ft. welding shop, to E. E. Christman St. Estimated cost, \$115,000. Noted Sept. 1.

ST. PAUL—The Western Chemical Co., 443 South Dearborn St., Chicago, Ill., has purchased a 30th St. and University Ave., and plans to build a factory and office on same. Estimated cost, \$100,000.

Mississippi

CLARKSDALE—D. W. Riechberger, 126 South 2nd St., Memphis, Tenn., and others have formed a company for the purpose of

building a plant to supply gas to this town. Estimated cost, \$10,000. An election will be held to determine whether citizens will accept proposition. J. H. Weatherford, Porter Bldg., Memphis, Tenn., engineer.

Missouri

HANNIBAL—The Hannibal Rubber Co. has awarded the contract for the construction of a rubber plant to Burger Bros., Hannibal. Estimated cost, \$100,000.

ST. LOUIS—Poro Collee, 4316 St. Ferdinand St., has awarded the contract for the construction of a 3-story, 46 x 125-ft. college at 4300 St. Ferdinand St., to T. H. Ratz, 917 Pine St. Laboratory equipment will be needed. Estimated cost, \$40,000.

ST. LOUIS—The Monsanto Chemical Works, 1840 South 2nd St., are building a 1-story, 56 x 141-ft. chemical factory at 1823-27 Koselusk St. Estimated cost, \$16,000.

ST. LOUIS—The St. Louis Metalware Co., 2503 North Broadway, has awarded the contract for the construction of a 2-story, 220 x 360-ft. factory, at 5735-37 Natural Bridge Rd., to the Gamble Construction Co., 620 Chestnut St. Estimated cost, \$66,000.

Nebraska

OMAHA—Farrell & Co., 10th and Dodge Sts., has awarded the contract for the construction of a 6-story, 60 x 106-ft. syrup and can manufacturing plant on the northwest corner of 9th and Dodge Sts., to Peter Kuehn & Sons, 754 5th St. National Bank Bldg. Estimated cost, \$200,000.

New Jersey

BAVONNE—The White Oil Corporation, 501 Fifth Ave., New York City, has purchased a 15-acre site along the waterfront, here, and plans to construct a modern distributing station for domestic and export business. Plans include five 75,000-bbl. tanks, fourteen 10,000-bbl. tanks, a canning plant and other buildings. Estimated cost, \$114,000.

JERSEY CITY—The Baker Castor Oil Co., Morgan St., plans to build a 1-story tile building to be used as a laboratory. Estimated cost, \$10,000.

JERSEY CITY—The Colgate Co., 105 Hudson St., manufacturer of soaps, has awarded the contract for the construction of an addition to its factory on York St., to the Turner Construction Co., 242 Madison Ave., New York City. Estimated cost, \$200,000.

TRENTON—The Maddock Pottery Co., 3rd St., plans to build a pottery plant, to include a 60 x 160-ft. kiln building, 2-story, 50 x 120-ft. plant and a 3-story, 60 x 120-ft. plant. Estimated cost, \$150,000. J. O. Hunt, 114 North Montgomery St., architect.

New York

ALBANY—The Albany Chemical Co., 2-24 Broadway, has awarded the contract for the construction of a 3-story, 57 x 69-ft. building, on Tuay and Gansevoort Sts., to F. J. Stevens, 85 Morris St. Estimated cost, \$53,000.

BOHVAR—L. C. Burt, Bradford, Pa., plans to erect a refinery here.

BROOKLYN—The C. W. H. Carter Co. is having preliminary plans prepared for altering building on Columbia, Sigourney and Bay Sts., and construction drum building, 200 Madison St. Estimated cost, \$100,000. McCarthy & Kelly, 16 Court St., engineer.

BUFFALO—The Buffalo Porcelain Enamelling Co. has awarded the contract for the construction of a 1-story, 60 x 140-ft. enameling plant, to the Crescent Concrete Co., Erie County Bank Bldg. Estimated cost, \$35,000.

LONG ISLAND CITY—The Pathe Exchange, Inc., 25 West 45th St., New York City, plans to build a 200 x 400-ft. laboratory on Anby St. Estimated cost, \$500,000.

NEW YORK—The Vitreous Enameling & Stamping Co., Inc., 11 East 167th St. (Bronx Boro) is having plans prepared for the construction of a 1-story, 70 x 172-ft. factory and garage on Sedgwick Ave. and 171st St. Estimated cost, \$80,000. W. J.

Finn, president, F. W. Finn, 70 West 181st St., architect and engineer.

NEW YORK—FALLS—The Carborundum Co., Buffalo Ave. and 14th St., has awarded the contract for the construction of a 2-story, 64 x 96-ft. factory addition on Buffalo Ave. to the Keirns Construction Co., Boston, Mass. Estimated cost, \$40,000.

OGDENSBURG—The Morgan Chemical Co. has taken over the plant of the Arnold Brewing Co. and will alter and build addition to same for its own use. Estimated cost, \$60,000. N. E. Morgan, Hermon, president.

North Carolina

CHARLOTTE—J. F. Harrison, Greensboro, has awarded the contract for the construction of a 62 x 125-ft. carbonic acid gas factory, to J. A. Gardner, Charlotte. Estimated cost, \$15,000.

GASTONIA—The city plans to extend sewerage and water systems and build a disposal plant. Estimated cost, \$100,000. W. M. Pratt, Durham, engineer.

ROCKY MOUNT—The Falcon Brick Co., plans to build a brick plant, 2-story, 60 x 60-ft. Work will be done by day labor.

North Dakota

MINOT—The city is having plans prepared for the construction of a sewerage system and a disposal plant. Estimated cost, \$25,000. Frederick H. Lewis, 515 Southeast 6th St., Minneapolis, Minn., engineer. Noted Oct. 15.

Ohio

AKRON—The Star Rubber Co., 1068 Switzer Ave., is having plans prepared for the construction of a 4-story, 60 x 110-ft. rubber factory on Switzer Ave. Estimated cost, \$75,000. Abbott Engineering Co., 5435 Prospect Ave., Cleveland, engineer.

CINCINNATI—The Rapid Electroyte, Canal St. near Race St., plans to build a 2-story, 100 x 215-ft. factory on McNicklen and Elm Sts., Zettell & Rapp, Mercantile Bldg., architects.

CLEVELAND—The Hydraulic Press Steel Co. has awarded the contract for the construction of a 1-story, 75 x 200-ft. factory addition on Hydraulic Ave., to the Craig-Curtiss Co., 1031 Guardian Bldg. Estimated cost, \$100,000.

GRAFTON—The village is having preliminary surveys made for the construction of a sewage disposal plant and water works. Estimated cost, \$100,000. R. W. Pratt, Hippodrome Bldg., Cleveland, engineer.

TOLEDO—The Standard Oil Co. of Ohio, East Ohio Gas Bldg., Cleveland, is in the market for \$15,000 worth of equipment for maintenance of its refinery here, and will require shears, milling machines, radial drills and similar equipment.

CLEVELAND—The Citizens Savings & Trust Co., Citizens Bldg., is having plans prepared for the construction of a 20-story, 258 x 383-ft. bank and office building on Euclid Ave. and East 9th St. A complete water purification and refrigerator plant will be installed in same. Estimated cost, \$8,000,000. Graham, Probst, Anderson & White, Railway Exchange Bldg., Chicago, architects and engineers.

CLEVELAND—The city is having preliminary plans prepared for the construction of a 160,000-gal. filtration plant. Estimated cost, \$5,000,000. Robert Hoffman, 618 City Hall, city engineer.

CLEVELAND—The Manufacturers Oil & Gas Co., Citizens Bldg., has awarded the contract for the construction of a 2-story, 78 x 83-ft. factory, to the Watson Engineering Co., 1101 Hippodrome Bldg. Estimated cost, \$15,000.

CLEVELAND—The Mechanical Rubber Co. has awarded the contract for the construction of a 5-story, 80 x 200-ft. factory on Lishon Rd., to Stone & Webster Co., 12 Broadway, New York City. Estimated cost, \$250,000.

CLEVELAND—The Monarch Brass Co., 4113 Payne Ave., has awarded the contract for the construction of a 2-story, 60 x 200-ft. factory on 45th St. and Payne Ave., to the Emerson Co., 1900 Euclid Bldg. Estimated cost, \$150,000.

ELYRIA—The city will receive bids in December for the construction of a complete waterworks system, including a filter house. Estimated cost, \$125,000. Morris Knowles, Jones Law Bldg., Pittsburgh, Pa., engineer.

KENMORE—The city will receive bids

after Jan. 1 for the construction of a sewage disposal plant, sedimentation tanks and basins. Estimated cost, \$80,000. J. W. Baughman, service director. W. W. Pratt, Hippodrome Bldg., Cleveland, engineer.

WILLIUGHBY—The Zenith Tire & Rubber Co., 455 Leder-News Bldg., Cleveland, has having plans prepared for the construction of a 3-story, 100 x 585-ft. rubber factory and power house. Estimated cost, \$500,000. A. W. Corbin, 829 Schofield Bldg., Cleveland, architect and engineer.

Oklahoma

CLEVELAND—The city, c/o Davis B. Heller, voted \$40,000 bonds for the construction of a gas plant and pipe line system.

EL RENO—The city has awarded the contract for the construction of a disposal and treatment plant, and the extension of the sanitary sewerage system, to Tibbels & Pleasant, 204 Daniel Bldg., Tulsa. Estimated cost, \$121,000. Noted Aug. 15.

MIOMINY—The city plans to construct a filtration plant in connection with the proposed water system. C. E. Lee, city engineer, preparing plans.

TULSA—The city plans to build a sewage disposal plant with capacity sufficient to take care of entire city. Estimated cost, \$250,000. C. E. Griggs, City Hall, city engineer.

Oregon

BEND—The Portland Cement Pipe Co., 410 River St., Portland, is having preliminary plans prepared for the construction of plant for the manufacture of cement pipe to be used in highway construction. Estimated cost, \$10,000. C. H. Bullen, 410 River St., manager.

LEXTON—The Associated Oil Co., Pittsford Bldg., Portland, has awarded the contract for the construction of an oil plant, including a septic tank, sewerage system, etc., to the Dinwiddie Construction Co., Yeon Bldg., Portland. Estimated cost, \$120,000.

Pennsylvania

ELLWOOD—The city plans to construct a sewage plant. C. C. Hall, city clerk. R. W. Pratt, Hippodrome Bldg., Cleveland, engineer. Noted May 1.

MINERS MILLS (Wilkes-Barre P. O.)—The Miner-Hillard Milling Co., Wyoming National Bank Bldg., Wilkes-Barre, plans to build 2-story, 40 x 80-ft. laboratories on Main St. Estimated cost, \$50,000.

NEW BRIGHTON—The city will receive bids next spring for the construction of a sewage disposal plant. F. R. O'Rourke, city clerk. R. W. Pratt, Hippodrome Bldg., Cleveland, Ohio, engineer.

STEELTON—The Bethlehem Steel Co. will build a 3-story, 61 x 13-ft. laboratory, Russell & Simler, Otis Bldg., 16th and Sansom Sts., architects.

Rhode Island

PROVIDENCE—George F. Berkander, 43 Sabin St., has awarded the contract for the construction of a 2-story, 60 x 204-ft. factory, for the manufacture of celluloid novelties, on Broad St., to F. G. Rowley Co., 260 Central Ave., Pawtucket. Estimated cost, \$100,000.

Tennessee

MEMPHIS—The Seven States Oil Co. plans to construct a modern crude oil refinery, here, to have a capacity of 2000 bbl. per day. Estimated cost, \$175,000. Address W. T. Berlin, chairman.

Texas

DUBLIN—The Pullman Oil & Refining Co., Ft. Worth, plans to construct a 1-story, 3500-bbl. refinery here. Site is about 20 miles from the Deadman Field. Estimated cost, \$300,000.

FT. WORTH—The Invader Oil & Refining Co., Texas State Bank Bldg., will receive bids until Dec. 10 for the construction of a 1 and 2-story, 60 x 200-ft. factory, here. Estimated cost, \$790,000. Address: Owen A. Wood, c/o Invader Oil & Refining Co.

HOUSTON—The Mack Manufacturing Co., Ltd., 821 Kress Bldg., has awarded the contract for the construction of six 1 and 3-story buildings, to the W. C. Hedrick Contracting Co., Houston. Buildings in-

clude foundry forge shops, pattern shops, offices and warehouses. Charles R. Edwards, superintendent of plant.

JACKSBORO—The Texas United Oil & Refining Co., Ft. Worth, plans to construct a 1-story refinery, here. Estimated cost, \$350,000.

TEXAS—Several officials of the White Oil Corporation, 501 5th Ave., New York City, are inspecting sites along the Texas coasts with a view to constructing a 15,000-bbl. refinery. Definite location not yet decided upon. Estimated cost, \$300,000. J. J. White, president. Engineer not yet selected.

Virginia

ORANGE—The city is having plans prepared for the installation of a filtration plant and water system. Estimated cost, \$70,000. Address A. J. Harlow, mayor, Saville & Claiborne, 7th and Main Sts., Richmond, engineers.

Wisconsin

CUDAHY—The Federal Rubber Co. has awarded the contract for the construction of a 2-story, 50 x 100-ft. rubber cement house, to the T. Siderts Construction Co., 1574 2nd St., Milwaukee. Estimated cost, \$60,000.

KEWASHUM—Leigh Hunt, architect and engineer, 501 Security Bldg., Milwaukee, will soon award the contract for the construction of a 2-story, 50 x 180 ft. factory, for the Kewashum Aluminum Co. Estimated cost, \$56,000.

MADISON—The Burgess Battery Co. plans to construct a 3-story, 165 x 235-ft. building consisting of offices, laboratories and housing for the plant equipment.

MILWAUKEE—The Great Lakes Malleable Co., 110 Reed St., has awarded the contract for the construction of a 1-story, 50 x 77-ft. annealing plant on Reed St., to John T. Stange, 144 Oneida St. Estimated cost, \$110,000.

RACINE—The J. I. Case Threshing Machine Co. has awarded the contract for the construction of a 1-story, 130 x 130-ft. testing building, to Nelson & Co., Robinson Bldg. Estimated cost, \$100,000.

SOUTH MILWAUKEE—The Universal Aniline Dyes & Chemical Co., 1009 Wells Bldg., plans to construct a 1, 2 and 3-story dye manufacturing plant, including a 1-story, 30 x 40-ft. laboratory, power house, main building, 2 or 3 dye houses, warehouse, office, etc. Estimated cost, \$200,000. O. C. Vehling, 511 First National Bank Bldg., Milwaukee, architect and engineer.

WEST BEND—The West Bend Aluminum Co. plans to build a 4-story, 70 x 190-ft. factory addition. Estimated cost, \$100,000. Federal Engineering Co., Stephenson Bldg., Milwaukee, architect and engineer.

Wyoming

CHEYENNE—A. A. Boernsen, architect, Cheyenne, will receive bids this year for the construction of a 4-story, 200 x 200-ft. hospital on 23rd and House Sts., for Laramie County. An apparatus and laboratory equipment will be installed in same. Estimated cost, \$300,000.

MORCROFT—The U. S. Oil Refining & Gas Co. plans to construct a 1-story oil refinery, here. Estimated cost, \$250,000.

British Columbia

ROSSLAND—The Consolidated Mining & Smelting Co. of Canada plans to construct a steel mine concentrator, having a daily capacity of 15,000 tons. Estimated cost, \$1,000,000.

Ontario

BOSTON CREEK—The Miller Independent Mines, Ltd., plans to install a new electrical plant at its gold mine here. C. A. Miller, superintendent.

BRANTFORD—The Water Commission has had preliminary plans prepared for the construction of a filtration plant and capacity about 1,000,000 gallons. Estimated cost, \$500,000 to \$600,000. T. Harry Jones, City Hall, city engineer. R. S. and W. S. Lea, New Birks Bldg., Montreal, consulting engineers.

COBERGICK—The Lake Huron Steel Corporation plans to construct a complete new 1-story steel plant, including a blowing mill for manufacturing steel billets, rods and steel for the automobile trade, and high grade steel products. Six Heroulet electric furnaces will be installed in same.

Estimated cost between \$6,000,000 and \$10,000,000. Edward H. Beck, chief engineer.

NEW TORONTO—The Canadian Photo Plays, Ltd., Kent Bldg., Toronto, has awarded the contract for the construction of a 3-story, 80 x 150-ft. moving picture studio on Hamilton Highway, to the Dundas Engine-ring Co., Kent Bldg. A complete dark room and photographic equipment will be installed in same. Estimated cost, \$150,000.

PETERBOROUGH—The city had plans prepared for the construction of a sewage disposal plant, consisting of a 2-story sedimentation tank, sprinkling filters and humus tanks. From the humus tanks the effluent will be discharged into the Otonabee River. Estimated cost, \$125,000. R. H. Parsons, city engineer.

PETERBOROUGH—The Board of Education has awarded the contract for the construction of a 2-story building to be used as a collegiate institute, to include a chemical and physical laboratory, to Graham & Hayes, Peterborough, \$159,963. Estimated cost, \$250,000.

WINDSOR—A. H. McPhail, architect, will soon award the contract for the construction of a 3-story high school for the Board of Education. Chemical and physical laboratories and equipment will be installed in same. Estimated cost, \$450,000.

Quebec

MONTREAL—The Lignite Utilization Board of Canada, 80 St. Francois St., will receive bids until Dec. 14 for furnishing briquetting machinery.

New Publications

A REPORT OF THE ACTIVITIES OF THE WAR DEPARTMENT IN THE FIELD OF INDUSTRIAL RELATIONS DURING THE YEAR 1918, published by the War Department, Sept. 15, 1919.

A RESTUDY OF THE STAUNTON GAS POOL. By L. A. Lylis. Extract from Bull. No. 44, State Geological Survey, Idaho, 1918.

THE OIL SHALES OF NORTHWESTERN COLORADO. Bull. No. 8, Aug. 1, 1919, published by the State of Colorado, Bureau of Mines, Denver, Colo.

"ASBESTOS" is the title of a new monthly magazine published in the interests of the asbestos and magnesite industry. The first issues appeared in July and each month since it has gone to its subscribers on the 15th. It is published by the Secretariat, Service, 721 Bulletin Bldg., Philadelphia, Pa.

U. S. FUEL ADMINISTRATION, Oil Division bulletin—Prices of Petroleum and its Products During the War. By Joseph E. Pogue and Isaac Lubin.

COLORADO SCHOOL OF MINES QUARTERLY, dated October, 1919, issued by the Colorado School of Mines, Golden, Colo.

WAR INDUSTRIES BOARD PRICE BULLETINS: No. 1, History of Prices During the War, by Wesley C. Mitchell; No. 4, Prices of Foods, by Murray S. Wildman; No. 5, Prices of Clothing, by John M. Curran; No. 6, Prices of Building Materials, by Homer W. Carleton; No. 23, Prices of Cotton and Cotton Products, by James Harvey Rogers, assisted by Grace M. Fairchild and Florence A. Dickinson; No. 24, Prices of Wool and Wool Products, by Katherine Snodgrass; No. 25, Prices of Silk and Silk Products, by Oscar B. Ryder; No. 26, Prices of Hides and Skins and Their Products, by A. W. Carleton, assisted by H. Kagan; No. 30, Prices of Rubber and Rubber Products, by Isador Lubin; No. 32, Prices of Iron, Steel, and Their Products, by Walter W. Stewart; No. 33, Prices of Petro-Alloys, Non-Ferrous and Rare Metals, by H. R. Aldrich and Jacob Schmuckler; No. 44, Prices of Paints and Varnishes, by Arthur Minnick; No. 45, Prices of Fertilizers, by H. L. Trumbull; No. 49, Prices of Soaps and Glycerine, by H. L. Trumbull; No. 51, Prices of Wood Distillation Products and Vanal Stores, by P. W. Carleton; No. 52, Prices of Natural Dyestuffs and Tanning Chemicals, by P. W. Carleton; No. 56, Prices of Explosives, by C. L. Fry; No. 57, Prices of Organic Chemicals, by Arthur Minnick.

NEW BUREAU OF STANDARDS PUBLICATIONS: Circ. No. 80, Protective Metallic Coatings for the Rustproofing of Iron and Steel, issued Oct. 1, 1919; Ser. Paper No. 340, A Standardized Method for the Determination of Solidification Points, Especially of Naphthalene and Paraffine, by M. W. Allen and L. Finkelstein, issued Sept. 12, 1919; Ser. Paper No. 342, Reflecting Power of Stellite and Lacquered

Silver, by W. W. Coblenz and H. Kahler, issued Sept. 11, 1919; Ser. Paper No. 343, Location of Flaws in Rifle-Barrel Steel by Magnetic Analysis, by R. L. Strickland and Wm. E. Koehnephew, issued Oct. 3, 1919; Ser. Paper No. 348, Use of a Modified Rosenhain Furnace for Thermal Analysis, by H. Scott and J. R. Freeland, issued Oct. 6, 1919; Ser. Paper No. 349, Photoelectric Spectrophotometry by the Null Method, by K. S. Gibson, issued Oct. 11, 1919; Tech. Paper No. 132, Analysis in Concrete, by E. B. Rosa, Burton McCollum and O. S. Peyer, 2nd ed., issued Aug. 1, 1919; Tech. Paper No. 131, Application of the Interferometer, by J. R. Freeland and Julius David Edwards, issued Oct. 6, 1919; Tech. Paper No. 132, Mechanical Properties and Resistance to Corrosion of Rolled Light Alloys of Aluminum and Magnesium With Copper, With Nickel, and With Manganese, by P. D. Merica, R. G. Waltenberg and A. N. Finn, issued Oct. 25, 1919; Tech. Paper No. 133, Tests of Flexibility and Tensile Strength of Aluminum, by Wm. E. Berry, issued Oct. 27, 1919; Tech. Paper No. 134, Experimental-Retort Tests of Orient Coal, by R. S. McBride and L. V. Trumbull, issued Oct. 28, 1919; Ser. Paper No. 35, Behavior of Wrought Manganese Bronze Exposed to Corrosion While Under Tensile Stress, by P. D. Merica and J. R. Freeland, issued Oct. 28, 1919; Tech. Paper No. 139, Some Tests of Light Aluminum Casting Alloys—The Effect of Heat Treatment, by P. D. Merica and C. K. Adams, issued Oct. 28, 1919; Tech. Paper No. 140, Constant-Temperature Still Head for Light-Oil Fractionation, by Frederick M. Washburn, issued Oct. 28, 1919.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 173-B, Wm. Minerals, Nitrogen Fixation and Production of Sodium Cyanide, by Van H. Manning; Bull. 178-D, Explosives and Miscellaneous Investigations; Tech. Paper 219, A New Method for Detecting Blown-Out Shots in Coal-Mines, by G. F. Hutchison and Jacob Barab; Tech. Paper 220, Burning Steam and Gas with Soft Coal, by U. S. Fuel Administration; Tech. Paper 222, Method of Administering Leases of Iron-Ore Deposits Belonging to the State of Minnesota; Ser. Paper No. 132, The Vapor Pressure of Lead Chloride, by E. D. Eastman and L. H. Duschak; Tech. Paper 226, Men Who Die of the Mines, by Miners' Association of Mine-Rescue Training July 1, 1916 to June 30, 1918, compiled by Dorsey J. Parker; Tech. Paper 231, Production of Explosives in the United States During the Calendar Year 1918, with notes on coal-mine accidents due to explosives and list of permissible explosives tested prior to March 31, 1919, by Albert H. Fay; Tech. Paper 232, Coke-Oven Accidents in the United States During the Calendar Year 1918, compiled by Albert H. Fay; Tech. Paper 242, Why and How Coke is Made by the Blast-Furnace Heating, by Henry Kreisinger and A. C. Fieldner; Tale Mining in Vermont, by Raymond B. Ladoo, mineral technologist.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: 1-3 Thin in 1918, by Adolph Knopf (Mineral Resources of the U. S., 1918, Part I), published Sept. 9, 1919; 1-4 Antimony in 1918, by Henry G. Ferguson (Mineral Resources of the U. S., 1918, Part I), published Oct. 18, 1919; 1-5, Prices of Coal and Coke 1913-1918, by C. E. Lesher (Mineral Resources of the U. S., 1918, Part I), published Oct. 18, 1919; 1-6, Prices of Sodium, Potassium, Calcium, Magnesium, Barium, Strontium, Bromine, and Calcium Chloride in 1918, by Ralph W. Stone (Mineral Resources of the U. S., 1918, Part II), published Aug. 16, 1919; 1-7, Prices of Sodium, Potassium, Calcium, Magnesium, Barium, Strontium, Bromine, and Calcium Chloride in 1918, by Ralph W. Stone (Mineral Resources of the U. S., 1918, Part II), published Aug. 27, 1919; 1-8, Magnesite in 1918, by Charles W. Yale and Tech. Paper 18, by Jefferson Middleton (Mineral Resources of the U. S., 1918, Part II), published Aug. 27, 1919; 1-9, Magnesite in 1918, by Charles W. Yale and Tech. Paper 18, by Jefferson Middleton (Mineral Resources of the U. S., 1918, Part II), published Sept. 16, 1919; 1-10, Sodium and Sodium Compounds in 1918, by Roger W. Stone (Mineral Resources of the U. S., 1918, Part II), published Oct. 24, 1919; 1-11, Phosphate Rock in 1918, by Ralph W. Stone (Mineral Resources of the U. S., 1918, Part II), published Oct. 24, 1919; 1-12, Shale in 1918, by G. F. Loughlin and A. T. Coons (Mineral Resources of the U. S., 1918, Part II), published Oct. 23, 1919; 1-13, Coal in 1918, by C. E. Lesher (Mineral Resources of the U. S., 1918, Part II), published Oct. 23, 1919; 1-14, Coal in 1918, by C. E. Lesher (Mineral Resources of the U. S., 1918, Part II), published Sept. 19, 1919; Preliminary Report of the Mineral Resources of the U. S. in 1918, published Aug. 7, 1919.

Supplement

Readers have doubtless noted the line in bold type appearing across the top of front cover, contents and first text page: "Published December 8th, With Current News." "Current News" can mean but one thing, and involves printing in each issue market reports compiled near the actual date of issue, rather than the serial date appearing in the running heads, which must be consecutive, according to postal regulations. Therefore, for statistical record, are assembled here the five weekly market reports and price lists intervening between that published in the issue of Oct. 22, mailed from Cooperstown, and this combined issue (Oct. 29-Nov. 5) mailed from New York. Market news now and hereafter is of the latest date consistent with proper printing and accuracy.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, Oct. 25.—Export sales have not developed.

Aluminum.—Transactions are mainly by direct contract. The open market continues quiet; 98-99 per cent ingots are quoted at 33c. per lb; cast scrap, 25-25½c.; sheet scrap, 23½-24c.; clippings, 27-28c.

Antimony.—The market is firm with no change in prices.

Copper.—Comparatively speaking, there are no transactions in copper taking place at present.

	Cents per Lb.
Copper, lake, spot.....	22.75 — 23.50
Copper, electrolytic, spot.....	21.25 — 22.50
Copper, casting, spot.....	21.50 — 21.50
Copper sheets, hot-rolled.....	32.00 —
Copper sheets, cold rolled.....	34.00 —
Copper bottoms.....	40.50 —
Copper rods.....	24.50 —
Copper wire.....	26.00 —
High brass wire and sheets.....	27.75 —
High brass rods.....	25.75 —
Low brass wire and sheets.....	29.50 —
Low brass rods.....	30.25 —
Brazed brass tubing.....	38.00 —
Brazed bronze tubing.....	43.25 —
Seamless copper tubing.....	35.50 —
Seamless bronze tubing.....	40.00 —
Seamless brass tubing.....	34.00 —
Scrap, heavy machinery comp.....	18.00 — 18.50
Scrap, heavy and wire.....	17.50 — 17.75
Scrap, light and bottoms.....	15.00 — 16.00
Scrap, heavy, cut and crucible.....	19.00 — 19.75
Scrap brass, heavy.....	10.25 — 10.75
Scrap brass, casting.....	12.00 — 12.50
Scrap brass, light.....	9.00 — 9.75
Scrap, No. 1 clean brass turnings.....	9.75 — 10.25
Scrap, No. 1 comp. turnings.....	15.75 — 16.00

Lead.—The price of lead has been steadily advancing and is quoted at 6.75-6.80c. New York, and 6.50c. East St. Louis.

Tin.—Due to the longshoremen's strike, tin is being quoted at 54.5c. lb. on shipboard, 55c. on docks and 56½c. from stock.

Zinc.—Similarly to the lead market, zinc has steadily advanced and is quoted at 7.75c. at East St. Louis and 7.80c. lb. at New York.

OTHER METALS

Bismuth..... lb.	\$2.95 — 3.75
Cadmium..... lb.	1.50 — 1.75
Cobalt..... lb.	2.50 — 3.50
Magnesium..... lb.	1.75 — 2.10

Palladium..... oz.	115.00 — 120.00
Platinum..... oz.	130.00 — 135.00
Silver..... oz.	1.19 —

The Iron and Steel Market

In terms of tonnage output now when the strike is entering its sixth week, production is at about 60 per cent of normal.

President Wilson's industrial or labor conference at Washington convened when the strike was two weeks old. It was being kept going, as well as it could be, in hope of there being interference from Washington, the strike having no chance of gaining anything by its own effort. The Senate Committee on Education and Labor investigated the strike and developed no sympathy whatever for it, and there remained the Labor Conference, which disbanded on Oct. 24.

The sharpest gain made in the past fortnight has been by the Lackawanna Steel Co. in the Buffalo district, which was closed entirely at the outset, but is now operating moderately well. The Mahoning Valley was closed entirely until late in the third week, when one or two blast-furnaces in Youngstown resumed, but even at the end of the fifth week the Valley was doing but little, its tonnage output not being over 15 or 20 per cent of normal. Such operations as are conducted are largely by men living within the mills.

Western Pennsylvania is now producing at nearly if not quite 90 per cent of normal. Small portions of the Pittsburgh district lie outside the county, including Donora and Monessen, up the Monongahela River, which were closed entirely and are now doing rather poorly, and Woodlawn, down the Ohio, which has operated practically normal throughout the strike.

There is a little operation in Cleveland, while the Wheeling district remains tightly closed. Gary and Chicago are doing somewhat better each week, but still very poorly.

At this writing the impending coal strike, set for Nov. 1, is a more serious matter to the iron and steel industry than its own strike. The mills have little coal in stock and could not have stocked much even if they had had an ample supply of labor. While the Connellsville coke region has hitherto been strictly non-union, the balance of probability seems to be that it would be seriously crippled eventually if the union coal miners should all strike.

Many of the steel mills are selling in more or less reserved manner to their regular customers, but chance buyers of steel can obtain practically nothing. The majority of manufacturing consumers are probably out of stock by this time and are presumably curtailing their operations somewhat, but little is heard of these troubles, for all buyers of steel are in strong sympathy with the mills, therefore do not complain.

The curtailment in steel production, following a condition of normal production being fully and eagerly absorbed at regular prices, the March 21 schedule, would easily cause prices to advance if the market were left to itself, but large conservative interests, including in particular the Steel Corporation, are practically certain to oppose price advances, at least during and immediately after the strike, if not for a long time afterward. A delivery premium market is likely to obtain, with regular prices done on deliveries at mill convenience.

The Chemical Market

New York, October 25, 1919.

The dock strike continues to be the potent factor influencing market conditions in New York. Among heavy chemicals interest has been focused on spot goods due to the difficulty in getting shipments on contracts. The past week has brought no change of conditions in the coal-tar market. While some spot supplies are to be found, they are of the less commonly used materials. Vegetable oils and naval stores have displayed opposite tendencies, the former upward, the latter weak and declining in price.

HEAVY CHEMICALS

Caustic soda and **soda ash** were the leaders, the bulk of the demand for the former being for export. Although English manufacturers of caustic soda are quoting under the American market, they are unable to make prompt deliveries. Japan, South America and Mexico are therefore turning to the United States. Three dollars and thirty-two cents per cwt. was probably the best that could be done for spot material, while most quotations ranged from \$3.40 to \$3.50. Supplies of soda ash in second hands are so limited that quotations are practically uniform, business depending mostly on the brand offered. One lot of 300 tons was sold at \$1.85 per cwt., but the price is now held at \$2.15 f.o.b. New York.

Only one or two dealers are holders of spot **formaldehyde**, and their price runs 25-27½c. per lb. Manufacturers' price for delivery next month is 24c.

The fact that one important manufacturer has stopped making **carbon bisulphide** means that none is to be had for prompt delivery.

There are a few weak holders of **sodium prussiate, yellow**, which condition is the main factor in keeping the market down to 24½c. per lb.

Although the quotation on **denatured alcohol** remains unaltered, it is nominal because of paucity of stocks.

VEGETABLE OILS

Owing to quotations from the Orient being higher and the fact that oils cannot be replaced at the figures which have been prevailing, the market displays an upward tendency. Coconut and soya bean oils have been in the greatest demand, while interest in chinawood oil has greatly decreased due to paint and varnish manufacturers being well stocked. Coconut oil owes its strong position to recent lack of importation, and soya bean to recent buying by soap manufacturers.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, OCT. 25, 1919

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....	lb.	\$1.00—\$1.10
Alpha naphthol, refined.....	lb.	1.40—1.50
Alpha naphthylamine.....	lb.	.32—50
Aniline oil, drums extra.....	lb.	.37—35
Aniline salts.....	lb.	.37—35
Anthracene, 80% in drums (100 lb.).....	lb.	.90—1.00
Benzaldehyde (f.f.c.).....	lb.	1.00—1.15
Benzidine.....	lb.	1.00—1.15
Benzidine, sulphate.....	lb.	.90—1.15
Benzoin acid, U. S. P.....	lb.	.90—1.10
Benzoin acid, U. S. P.....	lb.	.85—1.10
Benzol, pure, water-white, drums (100 lb.).....	gal.	.35—36
Benzol, 90% in drums (100 lb.).....	gal.	.35—36
Benzyl chloride, 95-97% refined.....	lb.	.35—40
Benzyl chloride, tech.....	lb.	.35—40
Beta naphthol, crude.....	lb.	3.25—4.50
Beta naphthol, sublimed.....	lb.	.75—80
Beta naphthylamine, sublimed.....	lb.	.45—55
Benzol, U. S. P., in drums (100 lb.).....	lb.	2.25—2.35
Ortho-cresol, in drums (100 lb.).....	lb.	.23—25
Cresylic acid, 97-99%, straw color, in drums.....	gal.	.80—85
Cresylic acid, 97-99%, dark, in drums.....	gal.	.85—90
Cresylic acid, 50% first quality, drums.....	gal.	.60—60
Dichlorobenzol.....	lb.	.07—10
Diethylaniline.....	lb.	1.40—2.25
Dimethylaniline.....	lb.	.55—60
Dinitrobenzol.....	lb.	.26—32
Dinitrochlorobenzol.....	lb.	.25—30
Dinitronaphthalene.....	lb.	.45—55
Dinitrophenol.....	lb.	.32—36
Dinitrotoluenol.....	lb.	.38—45
Dip oil, 25% tar acids, ear lobe, in drums.....	gal.	.38—65
Diphenylamine.....	lb.	.58—75
H-acid.....	lb.	1.60—1.75
Metaphenylnaphthylamine.....	lb.	.18—18
Monochlorobenzol.....	lb.	.12—15
Mononitrobenzylamine.....	lb.	1.50—1.75
Naphthalene, crude, in bbls. (250 lb.).....	lb.	.06—06
Naphthalene, fakes, in drums (100 lb.).....	lb.	.06—07
Naphthalene, balls.....	lb.	.08—10
Naphthalenic acid, crude.....	lb.	.75—1.25
Nitrobenzol.....	lb.	.12—19
Nitro-naphthalene.....	lb.	.35—45
Nitro-toluenol.....	lb.	.27—20
Ortho-amidophenol.....	lb.	3.00—4.25
Ortho-dichlorobenzol.....	lb.	.30—35
Ortho-nitrophenol.....	lb.	.90—1.25
Ortho-nitro-toluenol.....	lb.	.25—40
Ortho-toluidine.....	lb.	.25—35
Para-amidophenol.....	lb.	.25—40
Para-amidobenzol, HCl.....	lb.	2.50—3.25
Para-dichlorobenzol.....	lb.	.15—18
Paranitraniline.....	lb.	.95—1.10
Para-nitro-toluenol.....	lb.	1.35—1.50
Paraphenylenediamine.....	lb.	2.50—4.00
Paratoluidine.....	lb.	1.75—2.50
Phthalic anhydride.....	ton	1.50—2.15
Phenol, U. S. P., drums (dest.), (240 lb.).....	gal.	2.50—1.16
Pyridin.....	lb.	3.50—3.75
Resorcin, technical.....	lb.	6.50—6.75
Resorcin, pure.....	lb.	.37—4.50
Silicylic acid, tech., in bbls. (110 lb.).....	lb.	.45—50
Salol.....	lb.	.90—95
Solvent naphtha, water-white, in drums, 100 gal. gal.....	gal.	.20—2.27
Solvent naphtha, fakes, heavy, in drums, 100 gal. gal.....	gal.	.25—1.14
Sulphuric acid, crude.....	lb.	.25—30

Tollidine.....	lb.	\$1.70	\$2.50
Toluidine, mixed.....	lb.	.45	.55
Toluol, in tank cars.....	gal.	.26	
Toluol, in drums.....	gal.	.27	.30
Xylidine, drums, 100 gal.....	gal.	.44	.50
Xylol, pure, in drums.....	gal.	.37	.45
Xylol, pure, in tank cars.....	gal.	.35	
Xylol, commercial, in drums, 100 gal.....	gal.	.23	.27
Xylol, commercial, in tank cars.....	gal.	.22	

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow.....	lb.	\$0.42	\$0.44
Beeswax, refined, yellow.....	lb.	.47	
Beeswax, white, pure.....	lb.	.64	.66
Carnauba, No. 1.....	lb.	.85	.87
Carnauba, No. 2, regular.....	lb.	.65	.78
Carnauba, No. 3, North Country.....	lb.	.48	.50
Japan.....	lb.	.18	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb.	.06	
Paraffine waxes, crude, scale 124-126 m.p.....	lb.	.06	
Paraffine waxes, refined, 118-120 m.p.....	lb.	.07	.08
Paraffine waxes, refined, 128-130 m.p.....	lb.	.09	
Paraffine waxes, refined, 133-135 m.p.....	lb.	.10	.11
Paraffine waxes, refined, 135-137 m.p.....	lb.	.12	.13
Stearic acid, single pressed.....	lb.	.26	.28
Stearic acid, double pressed.....	lb.	.27	.29
Stearic acid, triple pressed.....	lb.	.31	.33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal.	\$1.10	
Pine tar oil, ref., sp. gr. 1.025-1.03.....	gal.	.96	
Pine tar oil, crude, sp. gr. 1.025-1.03 tank cars f.o.b. Jacksonville, Fla.....	gal.	.34	
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal.	.65	
Pine tar, ref., thin, sp. gr. 1.080-1.960.....	gal.	.38	
Turpentine, refined, sp. gr. 0.900-0.970.....	gal.	.23	.24
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal.	.30	
Pinewood creosote, ref.....	gal.	.48	

Naval Stores

The following prices are f.o.b. New York, for carload lots.

Rosin B-D, bbl.....	280 lb.	\$17.30	
Rosin F-I.....	280 lb.	18.35	18.95
Rosin K-N.....	280 lb.	20.20	22.40
Rosin W-G, 100 lb. W.....	280 lb.	16.00	17.00
Wood rosin, bbl.....	gal.	1.63	1.65
Spirits of turpentine.....	gal.	1.50	
Wood turpentine, steam dist.....	gal.	1.48	
Wood turpentine, deat. diet.....	200 lb.	8.25	8.50
Pine tar pitch, bbl.....	280 lb.	13.50	14.25
Tar, kiln burned, bbl. (500 lb.).....	280 lb.	14.50	14.90
Retort tar, bbl.....	gal.	.86	.93
Rosin oil, first run.....	gal.	.88	.93
Rosin oil, second run.....	gal.	.95	1.10
Rosin oil, third run.....	gal.	1.05	1.15
Rosin oil, fourth run.....	gal.		

Solvents

73-76 deg., steel bbl. (85 lb.).....	gal.	\$0.33	
70-72 deg., steel bbl. (85 lb.).....	gal.	.31	
68-70 deg., steel bbl. (85 lb.).....	gal.	.30	
V. M. and P. naphtha, steel bbl. (85 lb.).....	gal.	.23	

Crude Rubber

Para—Upriver fine.....	lb.	\$0.51	\$0.52
Upriver coarse.....	lb.	.34	
Upriver carboil.....	lb.	.34	.37
Plantation—First latex crepe.....	lb.	.53	
Ribbed smoked sheets.....	lb.	.52	
Brown crepe, thin, clean.....	lb.	.42	.48
Amber crepe No. 1.....	lb.	.48	

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b. New York.

Castor oil, No. 3, in bbls.....	lb.	\$0.18	\$0.19
Castor oil, A.A. bbl.....	lb.	.21	
China wood oil, in bbl.....	lb.	.22	.22
Cocoon oil, Ceylon grade, in bbl.....	lb.	.17	.18
Cocoon oil, Cochio grade, in bbl.....	lb.	.18	
Corn oil, crude, in bbl.....	lb.	.17	.18
Cottonseed oil, crude (f.i.b. mill).....	lb.	.18	
Cottonseed oil, summer yellow.....	lb.	.23	.24
Cottonseed oil, winter yellow.....	lb.	.24	.25
Lined oil, raw, car lots.....	gal.	1.70	1.73
Lined oil, raw, tank cars.....	gal.	1.65	1.70
Lined oil, boiled, car lots.....	gal.	1.70	1.74
Lined oil, commercial.....	gal.	2.40	2.50
Olive oil, commercial.....	lb.	.17	.17
Palm, Lagos.....	lb.	.16	.17
Palm, bright red.....	lb.	.16	.17
Palm, Niger.....	lb.	.21	.22
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.26	.27
Peanut oil, refined, in bbl.....	lb.	.27	
Rapeseed oil, refined in bbl.....	gal.	1.50	1.60
Rapeseed oil, blow, in bbl.....	gal.	1.60	1.70
Soya bean oil (Manchurian), in bbl.....	lb.	.17	.18
Soya bean oil, tank cars, f.o.b. Pacific Coast.....	lb.	.16	.16

FISH

Winter pressed Menhaden.....	gal.	\$1.20	
Yellow bleached Menhaden.....	gal.	1.1	
White bleached Menhaden.....	gal.	1.25	
Blown Menhaden.....	gal.	1.30	

Miscellaneous Materials

All Prices f.o.b. N. Y.

Barytes, domestic, white, fluted.....	ton	\$25.00	\$36.00
Barytes, oil color.....	ton	20.00	25.00
Blanc fixe, dry.....	lb.	.03	.04
Blanc fixe, pulp.....	ton	35.00	47.50
Cashin.....	ton	.05	.07
Chalk, English, extra light.....	lb.	.18	
Chalk, English, light.....	lb.	.04	.06

Chalk, English, dense.....	lb.	\$.04	\$.05
China clay (Kaolin), imported, lump.....	ton	25.00	35.00
China clay (Kaolin), imported, powdered.....	ton	30.00	60.00
China clay (Kaolin), domestic, lump.....	ton	10.00	20.00
China clay (Kaolin), domestic, powdered.....	ton	25.00	40.00
Feldspar.....	ton	12.00	16.00
Fluorspar, acid grade, lump, f.o.b. mines.....	net ton	30.00	35.00
Fluorspar, acid grade, ground, f.o.b. mines.....	net ton	30.00	40.00
Fuller's earth, domestic, powdered.....	ton	30.00	40.00
Fuller's earth, imported, powdered.....	ton	30.00	40.00
Pumice stone, imported.....	lb.	.03	.06
Pumice stone, domestic.....	lb.	1.04	
Shellac, TN.....	lb.	1.00	
Shellac, D. C.....	lb.		
Shellac, V. S. O.....	lb.		
Shellac, Diamond.....	lb.		
Shellac, orange, fine.....	lb.	1.05	
Shellac, orange, superfine.....	lb.	1.10	1.30
Shellac, A. C. garnet.....	lb.	1.00	
Shellac, bleached, fine.....	lb.	1.25	
Shellac, bleached, fresh ground.....	lb.	1.20	
Soapstone.....	ton	15.00	25.00
Talc, domestic.....	ton	16.00	60.00
Talc, imported.....	ton	55.00	60.00

Refractories

Following prices are f.o.b. works:

Chrome brick.....	net ton	80-90 at Chester, Penn.
Chrome cement.....	net ton	45-50 at Chester, Penn.
Clay brick, 14 quality fireclay.....	net ton	35-45 at Clearfield, Penn.
Clay brick, 2nd quality.....	net ton	30-35 at Clearfield, Penn.
Magnesite, dead burned.....	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2 in.....	net ton	80-90 at Chester, Penn.
Silica brick.....	net ton	41-45 at Mt. Union, Penn.

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon.....	lb.	.25	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon.....	lb.	.70	
Ferro-manganese, 70-80% Mn.....	gross ton	105.00	115.00
Spiegel, 16-20% Mn.....	gross ton	35.00	36.00
Ferro-molybdenum, per lb. of Mo.....	lb.	2.50	3.00
Ferro-silicon, 50%.....	gross ton	85.00	95.00
Ferro-silicon, 75%.....	gross ton	150.00	170.00
Ferro-silicon, 90%.....	gross ton	200.00	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.....	lb.	1.25	1.40
Ferro-uranium, 35-50%, of U.....	lb.	7.00	
Ferro-vanadium, 30-40% per lb. of contained V.....	lb.	5.50	7.00

Ores and Semi-finished Products

Chrome ore, 35-40%, C. O.....	unit	\$0.60	\$0.80
Chrome ore, 48% and over.....	unit	.85	1.00
Coke, foundry, f.o.b. ovens.....	net ton	5.50	6.00
Coke, furnace, f.o.b. ovens.....	net ton	4.00	5.00
Petroleum coke, refinery, Atlantic seaboard.....	net ton	20.00	25.00
Fluorspar, gravel, f.o.b. mines.....	net ton	.50	.75
Manganese ore, 45% Mn and over.....	unit	.50	.75
Manganese ore, chemical (MnO ₂).....	gross ton	60.00	70.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂	lb.	.75	.85
Tungsten, Scheelite, 60% WO ₃ and over, per unit of WO ₃	unit	9.00	15.00
Tungsten, Wolframate, 60% WO ₃ and over, per unit of WO ₃	unit	7.50	10.00
Ironium oxide, 96%.....	lb.		
Vanadium pentoxide, 99%.....	lb.	6.00	
Pyrites, foreign, lump.....	unit	.13	.35
Pyrites, foreign, fine.....	unit	.13	.35
Pyrites, domestic, fine.....	unit	.14	.17
Ilmenite, 52% TiO ₂ , f.o.b. N. Y.....	net ton	40.00	
Rutile, 95% TiO ₂ , f.o.b. N. Y.....	net ton	220.00	
Carbide, minimum 25% U ₃ O ₈ , per lb. of U ₃ O ₈	unit		3.00
Zircon, washed, iron free, f.o.b. N. Y.....	net ton	200.00	
Monazite, per unit of ThO ₂ , f.o.b. N. Y.....	unit	42.00	

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags.....	bbl.	\$2.80	
Lump lime, common, including container.....	300 bbl.	2.65	
Common brick, at dock.....	M.	48.00	
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago.....	M.	50.00	
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis.....	M.	40.00	
Roofings, tar pitch (14 lb. per 100 sq. ft.).....	ton	70.00	
Roofings, tar pitch (16-18 lb. bbl.) carlots.....	ton	34.00	
Roofings, asphalt pitch carlots.....	ton	34.00	
Roofings, asphalt felt carlots.....	ton	68.00	
Roofings, slate-surfaced, per roll, 100 sq. ft. carlots.....	ton	6.25	
Roofings, slate-finished slating, 100 sq. ft. carlots.....	ton	6.00	
Lined oil, raw in barrels.....	gal.	1.75	
Lined oil, 5 gal. cans.....	gal.	1.88	
Red lead, dry, 100 lb. keg.....	lb.		
Red lead, in oil, 100 lb. keg.....	lb.	1.44	
Red lead, dry, 5 lb. cans.....	lb.	.15	
Red lead, in oil, 5 lb. cans.....	lb.	.16	
White lead, dry and in oil, 100 lb. keg.....	ton	3.35	
White lead, dry and in oil, 25 and 50 lb. kegs.....	ton	1.34	
White lead, dry and in oil, 5 lb. cans.....	lb.	.15	

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45	
Angles, 3 to 6-in., 1-in. thick.....	100 lb.	2.45	
Tees, 3-in. and larger.....	100 lb.	2.45	
Plates.....	100 lb.	2.66	
Rivets, structural 3-in. and larger.....	100 lb.	4.20	
Rivets, conehead for boilers, 1-in. and larger.....	100 lb.	4.30	
Sheets, No. 28 black.....	100 lb.	4.35	
Sheets, No. 28 galvanized.....	100 lb.	5.70	
Sheets, No. 28 galvanized.....	100 lb.	5.70	

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c. all gages.

Current Market Reports

The Non-Ferrous Metal Market

Friday, Oct. 31.—A tendency to advance prices is noted wherever sufficient demand exists to warrant it.

Aluminum:—Ingot aluminum continues at the old fixed price of 33c. lb.

Antimony:—The demand for antimony is good and prices are from 84 to 9c. lb.

Copper:—No important trading is taking place with 22c. lb. being asked.

Copper sheets, hot-rolled.	lb.	\$0 32
Copper bottoms.	lb.	.40
Copper rods.	lb.	.28
Copper wire.	lb.	.28
High brass wire and sheets.	lb.	.26
High brass rods.	lb.	.26
Low brass wire and sheets.	lb.	.25
Low brass rods.	lb.	.30
Brazed brass tubing.	lb.	.38
Brazed bronze tubing.	lb.	.43
Seamless copper tubing.	lb.	.35
Seamless brass tubing.	lb.	.43
Seamless brass tubing.	lb.	.34
Bronze (gold) powder.	lb.	1.00

Lead:—Large quantities of lead, such as white lead pigments, are being absorbed in peace-time pursuits. Prices range from 5.85 to 6c. lb.

Zinc:—This market continues to strengthen, with 7.7c. lb. being the present level.

OTHER METALS

Bismuth.	lb.	\$3.20 — \$3.65
Cadmium.	lb.	1.40 — .
Cobalt.	lb.	2.50 — 3.50
Magnesium.	lb.	1.75 — 2.10
Mercury.	75 lb.	95.00 — .
Nickel.	lb.	.45 — .
Iridium.	oz.	175.00 — .
Palladium.	oz.	115.00 — 120.00
Platinum.	oz.	130.00 — .
Silver.	oz.	1.23 — .

The Iron and Steel Market

Much less scarcity of steel is reflected than was expected would be developed by six weeks of even a very partial strike. There are few cases of manufacturing consumers having had to curtail their operations, though possibly a few weeks more of a 60 or 70 per cent steel production might force many to do so. Steel mills are indisposed to discuss the extent to which they have been modifying their distribution of steel for the purpose of helping customers most in need of steel, but it is probable that much of this has been done, and it is generally understood that shipments have been much heavier, proportionately, to manufacturing consumers than to jobbers. Stocks of the latter are now showing signs of being ragged.

It is practically certain that the United States Steel Corporation and some at least of the large independents will oppose there being any advances in finished steel prices. Small mills, that do not normally sell far ahead, will probably be able to secure delivery premiums, and indeed a little business of this description has already been done, particularly in sheets and merchant bars.

Pig iron, on the other hand, is advancing rather sharply as to foundry grade, this being a continuation and an accentuation of the advancing tendency that was first apparent at the close of last June. Buffalo and Birmingham showed the first stiffening, about July 1, being followed by Philadelphia. Lately Cleveland and Chicago have begun advancing, and in the past week foundry iron at valley furnaces has become quotable at \$2 advance, for forward deliveries, making \$28.75, furnaces, against the March 21 price of \$26.75. The strike has not curtailed the operation of iron foundries, while it has somewhat curtailed the production of merchant iron, perhaps by a slightly greater extent than the consumption by steel works that use merchant iron has been curtailed.

A weighted average of pig iron prices shows that, with the recent advances, pig iron is now 81 per cent above its ten-year pre-war average, or the same percentage that is shown by a similar comparison of the March 21 prices of finished steel, which still rule. The Dun and Bradstreet index numbers show a mean advance of 120 per cent above their ten-year pre-war averages.

The Chemical Market

New York, November 1, 1919.

Although the harbor strike here has caused a great amount of inconvenience, to date it has not created an acute situation. Available supplies are rapidly diminishing, but the general opinion is that the situation will clear before the shortage becomes general. Naval stores are probably in a worse plight than other commodities. There are practically no spot supplies of rosins or spirits of turpentine available. But in their case, as in that of many other products, there are supplies in the harbor either on lighters or aboard ship. Coal-tar products are in the same position they have held for some weeks past, the bulk of activity being centered on meeting previous contracts. While there is a scarcity of paratoluidine, paranitrophenol, dinitrophenol, dimethylaniline, aniline oil and salts, there are fair quantities of supplies of other coal-tar products available in which a good business is being done. Aniline oil is being offered on contract for delivery next year at 28c. per lb. Vegetable oils have maintained a firm tone, although the market at present is mostly speculative. The crude rubber market was dull throughout the week until Friday, when it gained some strength due to stronger foreign markets. There were a few inquiries from manufacturers, but the major activity was confined to trading among dealers. Stocks of rubber in store are limited; there are, however, large quantities on steamers in the harbor. As a natural result of the lifting of the steel strike, business in ores and ferro-alloys is beginning to revive. Indicative of this is the good domestic inquiry reported for tungsten ore, high grade wolframite and for ferromanganese. Several thousand tons of spiegeleisen have been sold to Holland and Belgium.

Chicago, October 31, 1919.

With the exception of a general increase of from 10 to 15 per cent in vegetable oils and a few isolated advances in certain items of the heavy chemical line, the market in this district presents no spectacular feature.

Heavy Chemicals:—Potassium prussiate, under steady demand, holds firmly to previously established high prices, \$1.10 per lb. being readily obtained for the red and 70c. for the yellow. Sodium bichromate shows slightly added strength with 14c. the current quotation. Acetone at 15c. is below quotations of a fortnight ago. With buyers sufficiently active to prevent any accumulation of surplus stocks, old prices of 34c. per lb. for solid caustic soda and 4c. for the granulated still hold good. Soda ash and bleaching powder both are quoted at 2c.

Vegetable Oils:—Following the slump in prices of all vegetable oils on Oct. 1, buyers have re-entered the market with the effect of stiffening all prices.

Miller grade coconut oil in tanks has recovered from the low quotation of 16½c. to 18½c., and spot corn oil is firmly held at 18-18½c. Offers of corn oil in tanks are not below 16c. Crude cottonseed is up 2c., 19c. being asked at present, 24c. still holding for prime summer yellow. Soya bean oil has shared in the general recovery, the current quotation being 16 to 16½c., Coast. Linseed oil continues to fluctuate, the quotation ruling today being \$1.73 per gal., which was the figure two weeks ago.

Flotation Oils, Naval Stores, in accordance with their habit of several months past, continue to hold much interest. Pine oil has been the most active, the .933 steam distilled having advanced from \$1.05 to \$1.25 per gal. in the past two weeks. A very definite shortage is the cause for this advance. This market supplies many manufacturers of disinfectants, paints, varnishes, and linoleum, and ore handlers, with great quantities of pine oil, and the recent prosperity of these various industrial lines has caused unusually heavy demand. Destructively distilled pine oil remains at 95c. per gal.

Turpentine, contrary to expectation, has continued to remain low, compared with prices earlier in the year. It has fluctuated from \$1.55 on Oct. 9 to \$1.50, and is today quoted at \$1.62.

Not much change has occurred in rosin, F being quoted at \$18 and W at \$24.

Sheets, No. 10 blue annealed.....	100 lb.	3.55	—	
Sheets, No. 28 galvanized.....	100 lb.	5.70	—	

For painted corrugated sheets, add 50c. per 100 lb. for 25 to 28 gage, 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c. all gages.

Current Market Reports

The Non-Ferrous Metal Market

Friday, Nov. 7.—The market continues quiet. Consumers are not taking on supplies at present prices.

Aluminum.—The price fixed during the war still continues. Consumers' supplies are still short. Ingots of 98-99 per cent are quoted at 33c. lb. Sheets, 18 gage and heavier, 42c. Powder, \$.70-\$1.40 lb.

Antimony.—Strong at 9-9½c. lb.

Copper.—A featureless market with price tending to descend.

	Cents per Lb.
Copper, lake.....	21.50
Copper, electrolytic.....	21.00
Copper, casting.....	20.00
Copper sheets, hot-rolled.....	32.50
Copper sheets, cold rolled.....	33.50
Copper bottoms.....	40.50
Copper rods.....	28.00
Copper wire.....	25.75
High brass wire and sheets.....	26.75
High brass rods.....	24.75
Low brass wire and sheets.....	29.50
Low brass rods.....	30.25
Brazed brass tubing.....	38.00
Brazed bronze tubing.....	43.25
Seamless copper tubing.....	35.50
Seamless bronze tubing.....	39.75
Seamless brass tubing.....	34.00
Bronze (gold) powder.....	100.00

Lead.—There is less activity. New York quotes from 6.75 to 6.90c. lb., and St. Louis 6.50c.

Tin.—Sales at 54½c. are reported, but important activity cannot be expected before shipping becomes normal.

Zinc.—There is a strong tone to the zinc market. New York quotes 8c. and East St. Louis 7.70c.

Silver..... oz.	1.23 — 1.25

The Iron and Steel Market

In the eighth week of the iron and steel strike the production of steel may be estimated at approximately 70 per cent of the rate obtaining just before the strike, this comparing with a rate of about 50 per cent when the strike was at its height. It should be noted, however, that production just before the strike, while at the highest rate of the year since February, was at only between 80 and 85 per cent of capacity. On the complete ending of the strike, as a strike, the total of working forces in the industry is likely to be less than before the strike, rather than more, since strike breakers have been employed to but a slight extent, while some men have gone back to the countries of their birth. Apart from the matter of numbers, working forces are more or less disorganized and will be for some time to come, so many men having shifted their employment. Restricted production is a prospect giving some of the manufacturers more concern than the loss in tonnage during the strike. During the strike customers are co-operative and sympathetic, while after the strike they are likely to be strenuous in their demands for deliveries.

The Wheeling district remains closed almost completely, but the Mahoning Valley is making substantial and moderately rapid recovery from its complete closing, production in the valley being now about 25 per cent of normal. The Chicago-Gary district has easily crossed the 50 per cent line, while Cleveland and Buffalo continue to gain. The South continues working in full, with the Ensley steel plant producing at above rated capacity, while the East is almost free from strike.

PIG IRON ADVANCES

Following sharp advances in eastern Pennsylvania and along the lake front, the western Pennsylvania and valley pig iron market shows a strong advancing tendency, but in that region the advances are not clear cut. There is

the phenomenon of sales of prompt iron being made at large advances, with the furnaces refusing to quote for 1920 deliveries, whereby the only market that exists, in actual transactions, shows a large advance and yet it is not certain that buyers would pay any considerably advanced prices for the extended deliveries.

Prices are now approximately as follows: F.o.b. valley furnaces: Bessemer, \$28 to \$29; basic, \$27 to \$28; foundry, \$29 to \$32; No. 2X foundry, delivered Philadelphia, \$34.10 to \$35.10; No. 2X foundry, Buffalo furnace, \$32 to \$33; foundry, delivered Cleveland, \$29.15 to \$31.15; foundry, f.o.b. Birmingham furnaces, \$29 to \$30.

The Chemical Market

New York, November 10, 1919.

While there is a fair volume of buying of heavy chemicals for immediate requirements, dealers are devoting most of their attention to the removal of their goods from ships that have been lying in the harbor for several weeks and to arranging for export shipments. The only added feature of the tight situation in coal-tar products is the recently developed foreign inquiry. There has been no particular interest in vegetable oils, due in great measure to the wide difference between sellers' and buyers' views. Prices on these oils as well as fish oils remain practically unchanged. An unprecedented demand for all grades of paraffine waxes has suddenly arisen both in domestic and export circles. All leading refiners have their output for the remainder of the year sold, some being sold up through the greater part of February. The wax market has been sluggish for some time, but this sudden activity on the part of paraffines has imparted life to the remainder of the list, although no price increases, excepting on paraffines, are announced. While cable advices are unsatisfactory, it is the general belief that Calcutta is short of supplies of shellac. In addition crop reports are very unsatisfactory. All indications, therefore, point to higher prices. There are still no spot supplies of the better grades of rosins available, such as WW, WG, H and I, or spirits of turpentine. Para and plantation grades of rubber have displayed opposite tendencies during the week. Manufacturers and dealers have shown an active interest in plantations for both spot goods and future deliveries. Quotations for spot and future have been on about the same level. Under the improved shipping conditions premiums are no longer being offered for spot goods. First latex crepe is quoted at 55c. per lb.

HEAVY CHEMICALS

Plenty of inquiries for heavy chemicals are running the gamut of the market at present, but the prices bid are below the dealers' figures. Manufacturers, whenever they can spare any of their output from contracts, are holding their products at high levels. A shortage of steel drums is beginning to be felt.

Sodium bichromate was the feature of the market during the week. The price jumped from 12½c. per lb. to 14½-15c. Heavy producers withdrew further offerings at 12½c., but there appears to be few odd lots in second hands. With the arrival of a heavy shipment of Norwegian *sodium nitrite*, a slight decrease in price on this article, now selling around 14c. per lb., is expected.

The extreme scarcity of *formaldehyde* has caused it to exceed all previous price levels. The few dealers who have any goods are asking 30c. per lb. A heavy tonnage of both *caustic soda* and *ammonium sulphate* has been sold to Japan at regular export prices. In domestic trading caustic soda has been slow. *Denatured alcohol* could not be obtained during the week and prices are nominal.

COAL-TAR PRODUCTS

Business in this field has been greatly accelerated by the large number of export inquiries, *alpha-naphthylamine* being slightly in the lead. While South America has placed some orders for this product, Japan has bought large quantities. *Ortho-toluidine* and *toluidine* are also in good request. While the orders for *toluidine* only average from 500-1000 lb. in quantity, the demand is steady.

Sulphuric, fuming, 20 per cent. (oleum) drums, ton	ton	25.00-32.00	32.00-40.00
Sulphuric, fuming, 20 per cent. (oleum) carboys, ton	ton	30.00-35.00	35.00-40.00
Tannic, U. S. P., lb.	lb.	1.35-1.45	1.35-1.45
Tannic (tech.), lb.	lb.	1.42-1.55	1.42-1.55
Tartaric, crystals, lb.	lb.	2.2-2.3	2.2-2.3
Tungstic, per lb. of WO ₃ , lb.	lb.	1.20-1.40	1.20-1.40
Alcohol, Ethyl, gal.	gal.	4.90-5.00	4.95-5.05
Alcohol, Methyl, gal.	gal.	1.30-1.35	1.35-1.38
Alum, denatured, 188 proof, gal.	gal.	5.5-6.0	5.5-6.0
Alum, denatured, 190 proof, gal.	gal.	5.4-5.6	5.6-6.0
Alum, ammonia lump, lb.	lb.	.031-.044	.044-.044
Alum, potash lump, lb.	lb.	.021-.081	.09-.091
Alum, chrome lump, lb.	lb.	.12-1.2	1.2-2.3
Aluminum sulphate, commercial, lb.	lb.	.011-.02	.021-.021
Aluminum sulphate, iron free, lb.	lb.	.021-.03	.031-.031
Aqua ammonia, 26 deg., drums (750 lb.), lb.	lb.	.08-1.08	.08-1.08
Ammonia, anhydrous, cylinders (100-15 lb.), lb.	lb.	13-13 1/2	14-14 1/2
Ammonium carbonate, powder, lb.	lb.	13-13 1/2	14-14 1/2
Ammonium chloride, granular (white salammoniac), lb.	lb.	12-13	13-14
Ammonium chloride, granular (gray salammoniac), lb.	lb.	12-12 1/2	13-13 1/2
Ammonium nitrate, lb.	lb.	10-11	11-12
Ammonium sulphate, lb.	lb.	10-11	11-12
Azyl acetate, lb.	lb.	3.65-3.75	3.65-3.75
Arsenic, oxide, lumps (white arsenic), lb.	lb.	1.04-1.1	1.04-1.1
Arsenic, sulphide, powdered (red arsenic), lb.	lb.	1.04-1.1	1.04-1.1
Barium chloride, ton	ton	85.00-90.00	100.00-100.00
Barium dioxide (peroxide), lb.	lb.	10-10 1/2	11-12
Barium nitrate, lb.	lb.	10-10 1/2	11-12
Barium sulphate (precip.) (blanc fixe), lb.	lb.	.03-.03 1/2	.03-.04
Bleaching powder (see calcium hypochlorite), lb.	lb.	10-10 1/2	11-12
Blue Vitriol (see copper sulphate), lb.	lb.	10-10 1/2	11-12
Borax (see sodium borate), lb.	lb.	10-10 1/2	11-12
Brimstone (see sulphur, roll), lb.	lb.	10-10 1/2	11-12
Bromine, lb.	lb.	65-75	65-75
Calcium acetate, cwt.	cwt.	2.00-2.05	2.00-2.05
Calcium carbide, lb.	lb.	.04-0.05	.04-0.05
Calcium chloride, fused, lump, ton	ton	19.00-25.00	30.00-40.00
Calcium chloride, granulated, lb.	lb.	.011-.012	.02-.021
Calcium hypochlorite (bleaching powder), cwt.	cwt.	2.25-2.50	2.25-2.50
Calcium peroxide, lb.	lb.	1.50-1.70	1.50-1.70
Calcium phosphate, monocasic, lb.	lb.	.09-.09 1/2	.09-.09 1/2
Calcium sulphate, precipitated, lb.	lb.	.06-.06 1/2	.06-.06 1/2
Carbonyl sulphide, lb.	lb.	10-11	12-14
Carbon tetrachloride, drums, lb.	lb.	10-11	12-14
Carbonyl chloride (phosgene), lb.	lb.	10-11	12-14
Caustic potash (see potassium hydroxide), lb.	lb.	10-11	12-14
Caustic soda (see sodium hydroxide), lb.	lb.	10-11	12-14
Chlorine, gas, liquid-cylinders (100 lb.), lb.	lb.	.05-.05 1/2	.08
Cobalt oxide, lb.	lb.	1.50-1.55	1.50-1.55
Copperas (see iron sulphate), lb.	lb.	1.50-1.55	1.50-1.55
Copper carbonate, green precipitate, lb.	lb.	1.50-1.55	1.50-1.55
Copper cyanide, lb.	lb.	1.50-1.55	1.50-1.55
Copper sulphate, crystals, lb.	lb.	.081-.081	.09-.09 1/2
Cream of tartar (see potassium bitartrate), lb.	lb.	1.50-1.55	1.50-1.55
Creosol salt (see sodium sulphate), lb.	lb.	1.50-1.55	1.50-1.55
Formaldehyde, 40 per cent., lb.	lb.	27-30	27-30
Glauber's salt (see sodium sulphate), lb.	lb.	27-30	27-30
Glycerine, lb.	lb.	20-21	20-21
Potash, resublimed, lb.	lb.	4.00-4.25	4.00-4.25
Iron oxide, red, lb.	lb.	.03-0.20	.03-0.20
Iron sulphate, (copperas), cwt.	cwt.	1.00-1.20	1.20-1.50
Lead acetate, normal, lb.	lb.	12-14	12-14
Lead arsenate, (paste), lb.	lb.	12-14	12-14
Lead nitrate, crystals, lb.	lb.	15-16	15-16
Litharge, lb.	lb.	.091-.10	.091-.10
Lithium Carbonate, lb.	lb.	1.50-1.55	1.50-1.55
Magnesium carbonate, technical, lb.	lb.	1.50-1.55	1.50-1.55
Magnesium sulphate, U. S. P., 100 lb.	100 lb.	2.00-2.65	2.25-3.00
Magnesium sulphate, commercial, 100 lb.	100 lb.	1.75-2.00	2.00-2.50
Nickel salt, double, lb.	lb.	14-15	15-16
Nickel salt, single, lb.	lb.	12-13	13-14
Phosgene (see carbonyl chloride), lb.	lb.	10-11	12-14
Phosphorus, red, lb.	lb.	60-70	60-70
Phosphorus, yellow, lb.	lb.	35-37	35-37
Potassium bicarbonate, lb.	lb.	25-26	25-26
Potassium bitartrate (cream of Tartar), lb.	lb.	25-26	25-26
Potassium bromide, granular, lb.	lb.	75-80	75-80
Potassium carbonate, U. S. P., lb.	lb.	55-60	55-60
Potassium carbonate, technical, lb.	lb.	55-60	55-60
Potassium chlorate, crystals, lb.	lb.	18-20	21-22
Potassium cyanide, 98-99 per cent., lb.	lb.	nominal	nominal
Potassium hydroxide (caustic potash), lb.	lb.	25-28	30-31
Potassium iodide, lb.	lb.	3.55-3.60	3.55-3.60
Potassium nitrate, lb.	lb.	19-21	21-22
Potassium permanganate, lb.	lb.	52-60	52-60
Potassium prussiate, red, lb.	lb.	1.05-1.15	1.05-1.15

		Carlots	Less Carlots
Potassium prussiate, yellow, lb.	lb.	1.05-1.15	1.05-1.15
Potassium sulphate, lb.	lb.	25-26	25-26
Rochelle salts (see sodium potas. tartrate), lb.	lb.	25-26	25-26
Salammoniac (see ammonium chloride), lb.	lb.	12-13	13-14
Salt cake (see sodium carbonate), lb.	lb.	12-13	13-14
Salt cake (sodium sulphate), lb.	lb.	12-13	13-14
Silver cyanide, lb.	lb.	1.90-2.00	1.90-2.00
Silver nitrate, lb.	lb.	1.90-2.00	1.90-2.00
Soda ash, light, 100 lb.	100 lb.	1.90-2.00	1.90-2.00
Soda ash, dense, 100 lb.	100 lb.	2.25-2.35	2.25-2.35
Sodium acetate, lb.	lb.	.07-07 1/2	.07-07 1/2
Sodium bicarbonate, 100 lb.	100 lb.	2.35-2.45	2.35-2.45
Sodium bicarbonate, (sal soda), lb.	lb.	1.35-1.50	1.35-1.50
Sodium bisulphate (nitric cake), lb.	lb.	3.00-3.00	3.00-3.00
Sodium bisulphate, cwt.	cwt.	1.80-1.90	2.00-2.10
Sodium borate (borax), lb.	lb.	.021-.021	.08-08 1/2
Sodium carbonate (sal soda), 100 lb.	100 lb.	1.35-1.50	1.50-1.75
Sodium chloride, lb.	lb.	1.35-1.50	1.35-1.50
Sodium cyanide, lb.	lb.	30-31	31-34
Sodium fluoride, lb.	lb.	14-15	15-16
Sodium hydroxide (caustic soda), 100 lb.	100 lb.	3.30-3.40	3.45-3.50
Sodium molybdate, lb.	lb.	2.50-2.60	2.50-2.60
Sodium nitrate, 100 lb.	100 lb.	2.87-3.25	3.25-4.00
Sodium nitrite, lb.	lb.	14-17	18-20
Sodium peroxide, powdered, lb.	lb.	10-11	12-13
Sodium phosphate, dibasic, lb.	lb.	.031-.04	.041-.05
Sodium potassium tartrate (Rochelle salts), lb.	lb.	25-26	25-26
Sodium prussiate, yellow, lb.	lb.	25-26	25-26
Sodium silicate, solution (40 deg.), lb.	lb.	.021-.021	.021-.021
Sodium silicate, solution (60 deg.), lb.	lb.	.021-.021	.021-.021
Sodium sulphate, crystals (Glauber's salts), cwt.	cwt.	1.15-1.25	1.50-2.00
Sodium sulphide, crystal, 60-62 per cent. (conch), lb.	lb.	.05-.06	.06-.06
Sodium sulphate, crystals, lb.	lb.	.031-.04	.041-.05
Strontium nitrate, crystals, lb.	lb.	25-26	28-30
Sulphur, lb.	lb.	.051-.06	.06-06 1/2
Sulphur, crude, lb.	lb.	22.00-22.00	22.00-22.00
Sulphur dioxide, liquid, cylinders, 100 lb.	100 lb.	10-11	10-11
Sulphur (sublimed), flour, 100 lb.	100 lb.	3.10-3.10	3.40-3.65
Sulphur, roll (brimstone), 100 lb.	100 lb.	2.95-3.00	3.15-3.40
Tin chloride (stannous), lb.	lb.	44-46	46-50
Tin oxide, lb.	lb.	20-21	20-21
Zinc carbonate, precipitate, lb.	lb.	12-13	13-14
Zinc chloride, gran., lb.	lb.	12-13	13-14
Zinc cyanide, lb.	lb.	.09-11	.09-11
Zinc dust, lb.	lb.	.09-11	.09-11
Zinc oxide, dry ammonia, lb.	lb.	.031-.031	.04-.04 1/2
Zinc sulphate, lb.	lb.	.031-.031	.04-.04 1/2

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude, lb.	lb.	\$1.00	\$1.00
Alpha naphthol, refined, lb.	lb.	1.35	1.50
Alpha naphthylamine, lb.	lb.	3.40	3.40
Aniline oil, drums extra, lb.	lb.	34-38	34-38
Aniline salts, lb.	lb.	90-100	90-100
Anthracene, 80% in drums (100 lb.), lb.	lb.	1.00-1.15	1.00-1.15
Benzaldehyde (f.i.c.), lb.	lb.	1.00-1.25	1.00-1.25
Benzidine, base, lb.	lb.	1.00-1.25	1.00-1.25
Benzidine, sulphate, lb.	lb.	90-110	90-110
Benzoin, U. S. P., lb.	lb.	85-110	85-110
Benzoin of soda, U. S. P., lb.	lb.	85-110	85-110
Benzol, pure, water-white, in drums (100 lb.), gal.	gal.	36-38	36-38
Benzol, 97% in drums (100 lb.), lb.	lb.	35-40	35-40
Benzyl chloride, 95-97%, refined, lb.	lb.	25-35	25-35
Benzyl chloride, tech., lb.	lb.	3.75-4.50	3.75-4.50
Beta naphthol, benzene, lb.	lb.	47-55	47-55
Beta naphthol, tech., lb.	lb.	2.25-2.35	2.25-2.35
Beta naphthylamine, sublimed, lb.	lb.	1.80-2.25	1.80-2.25
Creosol, (U. S. P.), in drums (100 lb.), lb.	lb.	1.80-2.25	1.80-2.25
Ortho-cresol, in drums (100 lb.), lb.	lb.	1.80-2.25	1.80-2.25
Creosylic acid, 95-97%, straw color, in drums, gal.	gal.	80-85	80-85
Creosylic acid, 95-97%, dark, in drums, gal.	gal.	85-90	85-90
Creosylic acid, 50% best quality, drums, gal.	gal.	60-100	60-100
Dichlorobenzol, lb.	lb.	1.40-2.25	1.40-2.25
Diethylaniline, lb.	lb.	38-63	38-63
Dimethylaniline, lb.	lb.	27-37	27-37
Dinitrobenzol, lb.	lb.	45-55	45-55
Dinitrochlorobenzol, lb.	lb.	33-36	33-36
Dinitronaphthalene, lb.	lb.	38-45	38-45
Dinitrophenol, lb.	lb.	33-36	33-36
Dinitrotoluenol, lb.	lb.	38-45	38-45
Diphenylamine, lb.	lb.	58-75	58-75
Hi-acid, lb.	lb.	1.55-1.70	1.55-1.70
Metaphenylenediamine, lb.	lb.	1.10-1.25	1.10-1.25
Monochlorobenzol, lb.	lb.	1.50-1.75	1.50-1.75
Mononethylaniline, lb.	lb.	1.06-1.08	1.06-1.08
Naphthalene crushed, in bbls (250 lb.), lb.	lb.	.06-.08	.06-.08
Naphthalene, flake, lb.	lb.	.06-.08	.06-.08
Naphthalene, benzene, lb.	lb.	.07-1.25	.07-1.25
Naphthalene, acid, crude, lb.	lb.	14-19	14-19
Nitrobenzol, lb.	lb.	35-45	35-45
Nitro-naphthalene, lb.	lb.	1.10-1.25	1.10-1.25
Nitro-toluenol, lb.	lb.	3.25-4.25	3.25-4.25
Ortho-amidophenol, lb.	lb.	1.95-2.20	1.95-2.20
Ortho-dichlorobenzol, lb.	lb.	1.95-2.20	1.95-2.20
Ortho-nitrophenol, lb.	lb.	1.95-2.20	1.95-2.20
Ortho-nitro-toluenol, lb.	lb.	1.95-2.20	1.95-2.20
Ortho-toluidine, lb.	lb.	2.25-3.50	2.25-3.50
Para-amidophenol, base, lb.	lb.	2.25-3.50	2.25-3.50
Para-amidophenol, HCl, lb.	lb.	2.25-3.50	2.25-3.50
Para-dichlorobenzol, lb.	lb.	1.10-1.20	1.10-1.20
Paranitraniline, lb.	lb.	1.35-1.50	1.35-1.50
Para-nitro-toluenol, lb.	lb.	2.30-3.40	2.30-3.40
Paraphenylenediamine, lb.	lb.	2.75-2.95	2.75-2.95
Paratoluidine, lb.	lb.	1.00-1.50	1.00-1.50
Phthalic anhydride, lb.	lb.	16-17	16-17
Phenol, U. S. P., drums (dest.), (240 lb.), lb.	lb.	2.90-3.25	2.90-3.25
Pyridin, lb.	lb.	3.50-3.75	3.50-3.75
Resorcin, technical, lb.	lb.	6.50-6.75	6.50-6.75
Resorcin, pure, lb.	lb.	90-95	90-95
Salicylic acid, tech., in bbls (110 lb.), lb.	lb.	45-50	45-50
Salicylic acid, U. S. P., lb.	lb.	40-45	40-45
Solvent naphtha, water-white, in drums, 100 gal. gal.	gal.	20-27	20-27
Solvent naphtha, crude, heavy, in drums, 100 gal. gal.	gal.	18-24	18-24
Sulphonic acid, crude, lb.	lb.	25-30	25-30

Tollidine.....	lb.	\$1.70	—	\$2.50
Tollidine, mixed.....	lb.	.45	—	.55
Toluol, in tank cars.....	gal.	.26	—	.30
Toluol, in drums.....	gal.	.27	—	.30
Xylidine, drugging, 100 gal.....	gal.	.44	—	.50
Xylol, pure, in drums.....	gal.	.37	—	.45
Xylol, pure, in tank cars.....	gal.	.35	—	.42
Xylol, commercial, in drums, 100 gal.....	gal.	.23	—	.27
Xylol, commercial, in tank cars.....	gal.	.22	—	.25

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow.....	lb.	\$0.41	—	\$0.43
Beeswax, refined, yellow.....	lb.	.47	—	.48
Beeswax, white, pure.....	lb.	.64	—	.66
Carnauba, No. 1.....	lb.	.85	—	.88
Carnauba, No. 2, regular.....	lb.	.78	—	.80
Carnauba, No. 3, North Country.....	lb.	.48	—	.50
Japan.....	lb.	.194	—	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb.	.06	—	.07
Paraffine waxes, crude, scale 124-126 m.p.....	lb.	.06	—	.07
Paraffine waxes, refined, 118-120 m.p.....	lb.	.08	—	.08
Paraffine waxes, refined, 128-130 m.p.....	lb.	.09	—	.09
Paraffine waxes, refined, 133-135 m.p.....	lb.	.11	—	.11
Paraffine waxes, refined, 135-137 m.p.....	lb.	.12	—	.13
Stearic acid, single pressed.....	lb.	.26	—	.28
Stearic acid, double pressed.....	lb.	.28	—	.30
Stearic acid, triple pressed.....	lb.	.32	—	.33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal.	\$1.10	—	
Pine oil, pure, dist. dist.....	gal.	.45	—	
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal.	.34	—	
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal.	.36	—	
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal.	.65	—	
Pine tar, ref., thick, sp. gr. 0.86-0.960.....	gal.	.104	—	
Turpentine, crude, sp. gr. 0.900-0.970.....	gal.	.85	—	
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal.	.30	—	
Finewood creosote, ref.....	gal.	.48	—	

Naval Stores

The following prices are f.o.b. New York, for earload lots.

Roisin B-D, bbl.....	280 lb.	\$17.50	—	
Roisin E-I.....	280 lb.	17.75	—	20.00
Roisin K-N.....	280 lb.	20.25	—	22.50
Roisin W, G-W, W.....	280 lb.	23.25	—	24.50
Wood rosin, bbl.....	280 lb.	16.50	—	17.00
Spirits of turpentine.....	gal.	1.70	—	
Wood turpentine, steam dist.....	gal.	1.50	—	
Wood turpentine, dist. dist.....	gal.	1.48	—	
Pine tar pitch, bbl.....	200 lb.	8.25	—	8.50
Tar, kiln burned, bbl. (500 lb.).....	bbl.	13.50	—	14.25
Retort tar, bbl.....	280 lb.	14.50	—	14.90
Rosin oil, first run.....	gal.	.86	—	.91
Rosin oil, second run.....	gal.	.86	—	.93
Rosin oil, third run.....	gal.	.95	—	1.10
Rosin oil, fourth run.....	gal.	1.05	—	1.15

Solvents

75-76 deg., steel bbl. (85 lb.).....	gal.	\$0.334	—	
70-72 deg., steel bbl. (85 lb.).....	gal.	.32	—	
65-70 deg., steel bbl. (85 lb.).....	gal.	.301	—	
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	.234	—	

Crude Rubber

Para-Upriver floor.....	lb.	\$0.514	—	\$0.524
Upriver floor.....	lb.	.331	—	.354
Upriver cauché ball.....	lb.	.341	—	.354
Plantation—First latex crepe.....	lb.	.55	—	
Ribbed smoked sheets.....	lb.	.471	—	.49
Brown crepe, thin, clean.....	lb.	.471	—	.49
Amber crepe No. 1.....	lb.	.52	—	

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b. New York.

Castor oil, No. 3, in bbls.....	lb.	\$0.181	—	\$0.19
Castor oil, AA, in bbls.....	lb.	.21	—	.22
China wood oil, in bbls.....	lb.	.22	—	.23
Cocanut oil, Ceylon grade, in bbls.....	lb.	.192	—	.20
Cocanut oil, Coochin grade, in bbls.....	lb.	.18	—	.184
Corn oil, crude, in bbls.....	lb.	.18	—	.184
Cottonseed oil, crude (f.o.b. mill).....	lb.	.194	—	.20
Cottonseed oil, summer yellow.....	lb.	.24	—	.24
Cottonseed oil, winter yellow.....	lb.	.24	—	.25
Lined oil, raw, car lots.....	gal.	1.70	—	1.75
Lined oil, raw, tank cars.....	gal.	1.65	—	1.70
Lined oil, winter yellow.....	gal.	1.70	—	1.72
Lined oil, boiled, car lots.....	gal.	2.40	—	2.50

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45	—	
Angles, 3 to 6-in, 4-in. thick.....	100 lb.	2.45	—	
Tees, 3-in. and larger.....	100 lb.	2.66	—	
Rivets, structural, 4-in. and larger.....	100 lb.	4.20	—	
Sheets, one-half for boilers, 4-in. and larger.....	100 lb.	4.30	—	
Sheets, No. 28 black.....	100 lb.	4.35	—	
Sheets, No. 10 blue annealed.....	100 lb.	3.55	—	
Sheets, No. 28 galvanized.....	100 lb.	5.70	—	

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 15c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

Current Market Reports

The Non-Ferrous Metal Market

Friday, Nov. 14.—Conditions are tending to improve, though the market is generally quiet.

Aluminum.—Virgin metal continues to be quoted at 33c. lb. in ingots, 98-99 per cent.

Antimony.—The price is advancing. New York spot quotes 94-95c. lb.

Copper.—Export trade is still featureless.

	Cents per Lb.
Copper, lake.....	21.25
Copper, electrolytic.....	20.00
Copper, casting.....	20.00
Copper sheets, hot-rolled.....	32.50
Copper sheets, cold-rolled.....	33.50
Copper bottoms.....	39.50
Copper rods.....	27.00
Copper wire.....	24.75
High brass wire and sheets.....	26.25
High brass rods.....	24.75
Low brass wire and sheets.....	28.75
Low brass rods.....	29.50
Brazed brass tubing.....	38.00
Brazed brass tubing.....	43.25
Seamless copper tubing.....	34.50
Seamless bronze tubing.....	37.00
Seamless brass tubing.....	33.50
Bronze (gold) powder.....	100.00

Lead.—The market is strong and another advance is expected. New York spot quoted at 6.75-7c. lb., St. Louis, 6.5-6.8c.

Tin.—Imports are quoted at 53½c. and spot 54½c.

Zinc.—Export orders for zinc have strengthened the market. Spot New York quoted at 8½c. and East St. Louis, 7.45-8c. lb.

The Iron and Steel Market

The iron and steel strike has ended its eighth week, with a production in that week equal to about 70 per cent of the rate just before the strike. The average operation in the eight weeks may be taken at 58 per cent of the pre-strike rate. Ingot production may be taken, for first three weeks of September, just before the strike, as at the rate of 41,000,000 tons a year. Except for the dislocation caused by the manufacture of shell steel during the war, with its heavy croppings, finished rolled steel has run quite uniformly at 76 per cent of the ingot tonnage. Using this factor, the production of finished rolled steel just before the strike was at the rate of 600,000 gross tons a week. In the eight weeks of strike this would have meant an output of 4,800,000 tons, while at 58 per cent the output was about 2,800,000 tons, showing what might be called a deficit of 2,000,000 tons. There can hardly be much additional deficit, no more than a very few hundred thousand tons. Production will then depend upon the number and efficiency of the men employed. There were deficiencies in both respects before the strike, and the same condition will apply in greater or less degree after the strike.

STEEL MARKET STRONG

While there is no large shortage of steel in point of tonnage, there are some consumers who are very short and are willing to pay substantial premiums for early deliveries. Offerings are so light that a very moderate demand, in point of tonnage, produces the appearance of there being an acute shortage, while in occasional instances very large premiums are offered, the record premium offered being \$30 a ton for automobile body sheets for prompt shipment.

There is no regular market quotable for early deliveries, as each bid or transaction is a case by itself. As to forward deliveries, the United States Steel Corporation's position is unaltered, that it does not approve of there being

any price advances. The deliveries, of course, were all in 1920, as the corporation was already sold up into that year. In sheets and tin plates the corporation has not yet opened its books for the new period, but some reservations are being accepted from regular customers.

PIG IRON ADVANCES

The advance in pig iron continues, the average in the past week being about a dollar a ton. Foundry iron is now quotable as follows for early delivery, there being practically no established market for extended delivery: Delivered Philadelphia, \$35.10; f.o.b. furnace: \$33, Buffalo; \$32, Cleveland; \$32, Chicago; \$30, Birmingham, and \$34, valley. Bessemer and basic pig iron have not participated in the advance to any extent. There have been sales of both grades to gray and malleable iron foundries, as substitutes for malleable or foundry iron, at prices higher than would be paid for steel making or ingot mold purposes. For regular use basic iron has brought \$27.25, valley and bessemer \$28.50.

The foundry iron furnaces are helping the advance by refraining from quoting for extended delivery, and later they may be able to enter the market with the same prices for extended delivery as they are now securing for prompt shipment.

The Chemical Market

New York, November 15, 1919.

There were no unusual features attaching to heavy chemicals during the week. Little can be added to previous statements concerning conditions among coal-tar products. Dimethylaniline is unobtainable in the local market except that here and there an odd lot can be located. The output of alphanaphthylamine from one important source at least is sold a month ahead. Although the vegetable oil market during the week assumed a little strength, there were on the whole few buyers, excepting those who wished to cover on speculations. Crude peanut oil was offered at 23½c. per lb., f.o.b. Pacific Coast; oleomargarine producers are beginning to enter the market for this oil. One hundred tons of chinawood oil in barrels was offered at 21c. per lb., f.o.b. Pacific Coast for Dec.-Jan. delivery, with tanks offered at the same price. Linseed oil is perceptibly stronger, which is attributable in the main to speculative influences in the flaxseed market. With the distribution of supplies of naval stores made available by the recent termination of the harbor strike to cover previous orders, there is still a scarcity of both spirits of turpentine and rosins. The crude rubber market closed with a steady tone, although it was dull during the greater part of the week. The slight manufacturing interest was on the basis of next year's requirements. There is little activity at present in either ores or ferro-alloys, particularly for export, owing to the adverse exchange situation. Tungsten is in an unsettled state pending the fate of the tariff measure on that ore. Foreign pyrites is still hard pressed because of the high freight rates and the difficulty in chartering steamers for its shipment.

HEAVY CHEMICALS

At the unchanged quotation of 14½-15c sodium bichromate is still the feature of the market. Offerings appearing were quickly absorbed, while producers are attending only to contract deliveries. The export demand is also strong.

Caustic soda and soda ash have reversed positions, the former now receiving the most attention. The bulk of this demand is for export, but the price offered by purchasers is inclined to fall below the Alkali Export Association price. This market, however, is well in the hands of manufacturers and buyers must meet the Association price of \$3.32½ per cwt.

Formaldehyde is still hovering around the record high figure of 30c. per lb. for spot goods, some quarters holding out for 32c. One leading manufacturer, however, endeavoring to eradicate the speculative influences and to give the regular consumer an opportunity to obtain supplies at a reasonable price, adheres to the old level of 19c.

Arsenic, ammonium sulphate and potassium carbonate are very scarce.

WHOLESALE PRICES IN NEW YORK MARKET, NOV. 15 1919

	lb.	oz.	gr.
Potassium prussiate, yellow.	ton	225	00

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2 45
Angles, 3 to 6-in, 1-in. thick.....	100 lb.	2 45
Tees, 3-in and larger.....	100 lb.	2 45
Plates.....	100 lb.	2 66
Beams, structural, 1-in. and larger.....	100 lb.	4 20
Beams, structural, for bolting, 1-in. and larger.....	100 lb.	4 20
Sheets, No. 28 black.....	100 lb.	4 35
Sheets, No. 16 blue annealed.....	100 lb.	3 55
Sheets, No. 28 galvanized.....	100 lb.	5 70
For painted corrugated sheets, add 30c. per 100 lb. for 23 to 25 gage, 25c. 10 to 24 gage. For galvanized corrugated sheets, add 15c. w/gage.		

Current Market Reports

The Non-Ferrous Metal Market

New York, Nov. 21.—There is little business in copper, even at the comparatively low price of 20c. (electrolytic). The tin market is sagging, with prices from 2 to 3c. lower than the high quotations for spot tin that prevailed during the dock strike, straits spot being freely offered at 53 to 53½c.

	Cents per lb.
Aluminum, virgin ingots	33.00
Antimony, spot wholesale	9.25
Lead, New York	6.80
St. Louis	6.55
Nickel, Ingot	42.00
Shot	43.00
Electrolytic	45.00
Zinc, New York	8.12
East St. Louis	7.75
Copper, soft untrimmed anodes	27.50
Copper, soft-rolled	28.25
Copper sheets, hot-rolled	30.00
Copper sheets, cold-rolled	32.00
Copper bottoms	38.00
Copper rods	27.00
Copper wire	25.75
High brass wire and sheets	25.25
Low brass rods	28.50
Brass tubing	37.00
Brass bronze tubing	42.25
Seamless copper tubing	34.50
Seamless bronze tubing	40.00
Seamless brass tubing	33.50
Copper nickel, hot-rolled rods (Constantan)	52.00
Monel metal, ingots	38.00
Monel metal, hot rolled sheets	55.00
Manganese nickel, cold drawn rods	70.00

The Iron and Steel Market

The iron and steel strike has been crumbling so rapidly that it is regarded as virtually over, but even with the return of the last of the strikers the mills would not be fully manned, in point of numbers, while really efficient operation cannot be expected for some time, possibly a few weeks, perhaps six months. There was a labor shortage before the strike and there will be at least as great a labor shortage afterwards. Temporarily at least the situation in this respect is made more acute by various mills adopting the 8-hr. shift in place of the 12-hr. shift.

VARYING PRICES

In steel products there are two classes of producers, from the price standpoint, and eventually there will be two sharply distinguished markets, one for delivery at mill convenience, the other for relatively prompt shipment. The Steel Corporation and some of the leading independents constitute one class of sellers, committed to the maintenance of March 21 prices, while the other class is composed of all the other producers. The last lines in which the Steel Corporation has entered the market for 1920 are sheets and tin plates, the American Sheet & Tin Plate Co. having opened its order books Nov. 15 for first quarter contracts in the case of jobbers and for first half contracts in the case of manufacturing consumers. Prices are strictly those of the March 21 schedule: Tin plate, \$7 per base box for 100-lb. plates; black sheets, 28 gage, 4.35c.; galvanized sheets, 28 gage, 5.70c.; blue annealed sheets, 10 gage, 3.55c., per lb., f.o.b. Pittsburgh.

Some independent sheet mills have been contracting with regular customers of long standing at these prices, but in all cases the tonnages sold are likely to prove less than the consumers require. Already some consumers have approached independent mills, stating that they could not place their entire tonnages at March 21 prices and expressing a willingness to pay advances for the balance they require.

PIG IRON

Pig iron is advancing at the rate of not far from a dollar a ton a week and is now about \$5 a ton, on an average, above the recent minimum, which fell about the beginning of July. The market for early deliveries now stands about as follows for foundry iron: Delivered Philadelphia, \$36.10; f.o.b. Buffalo, \$35; delivered Cleveland, \$32.40; f.o.b. Chicago, \$32; f.o.b. Birmingham, \$31. At valley furnaces the market stands: Bessemer, \$31.50; basic, \$30; malleable, \$32 to \$33; foundry, \$33 to \$34; freight to Pittsburgh being \$1.40.

The Chemical Market

New York, November 22, 1919.

The only development of note in the heavy chemical market since the last review is the receipt of a number of inquiries from Europe. The vegetable oil market fluctuated slightly during the early part of the week, and now shows indications of a decline. China-wood and peanut oils have been exceptions, however, they alone holding fairly steady. Despite the fact that quantities of linseed oil have arrived from England, this oil continues to maintain its ground in the local market. Fish oils have been receiving a fair export inquiry. As has been the case for a time, the para grades of rubber are quiet while trading in plantation grades by dealers is active. Ribbed smoked sheets, after dropping to 51½c. per lb. for January-June delivery, recovered to 53c.

That business in the ceramic trade and among glass, enamel-ware and varnish manufacturers is thriving is revealed by the fact that producers of feldspar are pushed to the limit to meet requirements. The consumption of barytes and blanc fixe is greater than the output, with the result that there is little of either in the open market. A large quantity of barytes has been shipped to Europe (England in particular) and to South America. Heavy demand and inability to furnish supplies led to the increases in price in barytes; domestic, white, rose from \$25-36 to \$35-40 per ton, while blanc fixe, pulp, was raised from \$35-47.50 to \$47.50-50.

HEAVY CHEMICALS

Sodium bichromate, that periodically fluctuating chemical, maintains the peak of interest in the local market. The price is 15-16c per lb. Both potassium-sulphate and potassium-muriate are difficult to locate at \$225 and \$200 per ton, respectively. Both caustic soda and soda ash are well controlled by manufacturers, with pleasing demand. Manufacturers are asking \$3.48 per cwt., f.o.b. works, for caustic and \$2.10-\$2.15 for the ash.

For sodium cyanide, 96-98 per cent, on contract over 1920, 25c per lb. is being quoted, 30c being the price for spot.

Chicago, November 20, 1919.

Under impetus of heavy export sales, soda ash and bleach have shown a slight advance, \$2.10 per cwt., f.o.b. works, now being asked, as against a price of \$2.05 previously. Caustic soda is very firm at \$3.35 per cwt. for the solid, an advance of 10c over previous quotation. The price of \$4 still holds good for caustic in granulated form. Sodium bichromate is repeating its performance of last July, having advanced 2c since early in October, 15c now being the current quotation. Acid prices, in the main, are steady. Current acid quotations are as follows: Sulphuric, 66 deg., \$20; 60 deg., \$13 per ton. Muriatic, 20 deg., \$12.25 in carloads.

Except for anilines, there have been no fluctuations in coal-tar products. The continued acute shortage in aniline oil has forced the price up to 33c., in drums, for less than carload lots, 32c. in carlots. Salicylic acid has again advanced after a slight fluctuation, and is now held firm at 45c.

All oils are holding the gain made three weeks ago, after the sharp slump the early part of October, the only change in price in the local market being in cottonseed oil, current quotation on crude now being 17c. Prime summer yellow holds at 24c. Corn oil holds at 18-18½c., depending on quantity, and linseed seems to have settled at \$1.73 per gal.

FLOTATION OILS, NAVAL STORES

Pine oil, with demand from metal workers steadily increasing and supply undeniably short, continues to advance; .933 pure steamed distilled is now quoted at \$1.35 per gal. in car lots, \$1.40 for less quantity, and destructively distilled brings \$1.25. There is none of the .920 grade of distilled being offered in this market. Turpentine is again up to \$1.72, and with a continuation of export sales, a higher figure can be anticipated. Rosin has shared in the general advance, with current quotation of F grade, \$19 and on WW grade \$24.50.

Carbon tetrachloride, drums.....	lb.	10	11
Carbonyl chloride (phosgene).....	lb.	75	80
Caulic potash (see potassium hydroxide).....	lb.	75	80
Caulic soda (see sodium hydroxide).....	lb.	75	80
Chlorine, gas, liquid-cylinders (100 lb.).....	lb.	05	05 1/2
Coal oil.....	lb.	1.50	1.55
Copperas (see iron sulphate).....	lb.	20 1/2	21
Copper carbonate, green precipitate.....	lb.	28	31
Copper cyanide.....	lb.	65	70
Copper sulphate, crystals.....	lb.	08 1/2	09 1/2
Copper of tartar (see potassium bitartrate).....	lb.	08 1/2	09 1/2
Epsom salt (see magnesium sulphate).....	lb.	19	20
Formaldehyde, 40 per cent.....	lb.	19	20
Glauber's salt (see sodium sulphate).....	lb.	20 1/2	21
Glycerine.....	lb.	4.50	4.55
Iodine, resublimed.....	lb.	03	04
Iron oxide, red.....	lb.	1.20	1.50
Iron sulphate, (copperas).....	cwt.	1.00	1.10
Lead acetate, normal (lead diacetate).....	lb.	12 1/2	14
Lead arsenate (paste).....	lb.	13	14
Lead nitrate, crystals.....	lb.	85	86 1/2
Litharge.....	lb.	09 1/2	10 1/2
Lithium Carbonate.....	lb.	13	14
Magnesium carbonate, technical.....	lb.	13	14
Magnesium sulphate, U. S. P.....	100 lb.	2.00	2.63
Magnesium sulphate, commercial.....	100 lb.	1.75	2.00
Melting salt, double.....	lb.	12	13
Nickel salt, single.....	lb.	12	15
Phosgene (see carbonyl chloride).....	lb.	60	70
Phosphorus, red.....	lb.	35	37
Potassium bicarbonate.....	lb.	25 1/2	26
Potassium bitartrate (cream of tartar).....	lb.	55	60
Potassium bromide, granular.....	lb.	2	2 1/2
Potassium carbonate, U. S. P.....	lb.	55	60
Potassium carbonate, crude.....	lb.	23	27
Potassium chlorate, crystals.....	lb.	18	20
Potassium cyanide, 98-99 per cent.....	nominal	30	31
Potassium hydroxide (caustic potash).....	lb.	25	28
Potassium iodide.....	lb.	3.55	3.60
Potassium nitrate.....	lb.	21	25
Potassium permanganate.....	lb.	1	58
Potassium prussiate, red.....	lb.	1.05	1.15

Potassium prussiate, yellow.....	lb.	1.05	1.15
Potassium sulphate.....	ton	225.00	240.00
Rochelle salts (see sodium potash, tartarate).....	lb.	1.05	1.15
Salammonias (see ammonium chloride).....	lb.	1.05	1.15
Salt soda (see sodium carbonate).....	lb.	1.05	1.15
Salt cake (sodium sulphate).....	ton	17.00	21.00
Silver cyanide.....	oz.	1	1.19
Silver nitrate.....	lb.	1.90	2.05
Soda ash, light.....	100 lb.	1.90	2.05
Soda ash, dense.....	100 lb.	2.15	2.25
Sodium acetate.....	lb.	06 1/2	07
Sodium bicarbonate.....	100 lb.	2.35	2.50
Sodium bisulphate.....	lb.	1.35	1.45
Sodium bisulphate (nitre cake).....	ton	3.00	3.50
Sodium bisulphate.....	cwt.	1.80	1.90
Sodium borate (borax).....	lb.	07 1/2	08
Sodium carbonate (anal soda).....	100 lb.	1.35	1.50
Sodium chloride.....	lb.	12	13
Sodium cyanide, 98-98 per cent.....	lb.	30	34
Sodium fluoride.....	lb.	15	16
Sodium hydroxide (caustic soda).....	100 lb.	3.35	3.40
Sodium molybdate.....	lb.	2.50	3.25
Sodium nitrate.....	100 lb.	2.87 1/2	3.25
Sodium nitrite.....	lb.	14	15
Sodium peroxide, powdered.....	lb.	3.35	3.45
Sodium phosphate, dibasic.....	lb.	03 1/2	04
Sodium potassium tartrate (Rochelle salts).....	lb.	1.05	1.15
Sodium prussiate, yellow.....	lb.	25	26
Sodium silicate, solution (40 deg).....	lb.	01 1/2	02
Sodium silicate, solution (60 deg).....	lb.	02 1/2	03 1/2
Sodium sulphate, crystals (Glauber's salt).....	cwt.	1.15	1.25
Sodium sulphate, crystals, 60-62 per cent (cone).....	lb.	05	06
Sodium sulphite, crystals.....	lb.	03 1/2	04
Sodium nitrate, crystals.....	lb.	25	28
Sulphur, crude.....	lb.	05 1/2	06
Sulphur dioxide, liquid, cylinders.....	lb.	22.00	24.00
Sulphur (sublimed), flour.....	100 lb.	3.10	3.40
Sulphur, roll (brimstone).....	100 lb.	2.95	3.15
Tin bichloride (stannous).....	lb.	3.10	3.40
Tin oxide.....	lb.	60	65
Zinc carbonate, precipitate.....	lb.	121	131
Zinc chloride, gran.....	lb.	121	131
Zinc cyanide.....	lb.	09	11
Zinc dust.....	lb.	09	11
Zinc oxide, dry American.....	lb.	09 1/2	09 1/2
Zinc sulphate.....	lb.	03 1/2	04

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....	lb.	\$1.00	\$1.10
Alpha naphthol, refined.....	lb.	1.40	1.50
Alpha naphthylamine.....	lb.	35	50
Aniline oil, drums extra.....	lb.	34	38
Aniline salts.....	lb.	36	40
Anthracene, 80% in drums (100 lb.).....	lb.	90	100
Benzaldehyde (l.f.c.).....	lb.	1.00	1.15
Benzidine.....	lb.	1.10	1.25
Benzoic acid, U. S. P.....	lb.	90	110
Benzoic acid, U. S. P.....	lb.	85	110
Benzoate of soda, U. S. P.....	gal.	24	28
Benzol, pure, water-white, drums (100 lb.).....	gal.	24	28
Benzol, 90% in drums (100 lb.).....	gal.	24	28
Benzyl chloride, 95-97% refined.....	lb.	35	40
Benzyl chloride, tech.....	lb.	35	35
Beta naphthol, bulk.....	lb.	3	40
Beta naphthol, sublimed.....	lb.	75	80
Beta naphthol, tech.....	lb.	47	55
Beta naphthylamine, sublimed.....	lb.	2.25	2.35
Benzol, U. S. P., drums (100 lb.).....	lb.	24	28
Ortho-cresol, in drums (100 lb.).....	lb.	23	25
Creosylic acid, 97-99% at raw color, in drums.....	gal.	80	85
Creosylic acid, 95-97% dark, in drums.....	gal.	85	90
Creosylic acid, 50% first quality, drums.....	gal.	80	85
Dichlorobenzol.....	lb.	07	10
Diethylamine.....	lb.	1.40	2.25
Dimethylamine.....	lb.	0.63	0.65
Dinitrobenzol.....	lb.	27	32
Dinitrochlorobenzol.....	lb.	25	30
Dinitrophenol.....	lb.	45	55
Dinitrophenol.....	lb.	27	36
Dinitrophenol.....	lb.	27	36
Dip oil, 25% tar acids, car lots, in drums.....	gal.	38	45
Diphenylamine.....	lb.	58	75
H-acid.....	lb.	1.55	1.70
Metaphenylenediamine.....	lb.	1.15	1.25
Monochlorobenzol.....	lb.	12	15
Monomethylaniline.....	lb.	1.00	1.25
Naphthalene crushed, in bbls (250 lb.).....	lb.	06	08
Naphthalene, balls.....	lb.	06	07
Naphthalene, balls.....	lb.	08 1/2	10
Naphthalenic acid, crude.....	lb.	75	1.25
Nitrobenzol.....	lb.	14	19
Nitro-naphthalene.....	lb.	35	45
Nitro-tolul.....	lb.	35	45
Ortho-amidophenol.....	lb.	3.75	4.25
Ortho-dichlorobenzol.....	lb.	15	20
Ortho-nitrophenol.....	lb.	90	1.25
Ortho-nitro-tolul.....	lb.	25	40
Ortho-toluidine.....	lb.	25	32
Para-amidophenol, base.....	lb.	2.75	3.50
Para-amidophenol, HCl.....	lb.	2.50	3.25
Para-dichlorobenzol.....	lb.	15	18
Paranitraniline.....	lb.	1.10	1.20
Para-nitro-tolul.....	lb.	1.35	1.50
Paraphenylenediamine.....	lb.	2.50	3.00
Paratoluidine.....	lb.	1.75	2.05
Phthalic anhydride.....	lb.	1.00	1.50
Phenol, U. S. P., drums (deat), (240 lb.).....	lb.	16	17
Pyridin.....	2.60	2.60	2.60
Resorcin, technical.....	lb.	3.50	6.75
Resorcin, pure.....	lb.	6.50	6.75
Salicylic acid, tech., in bbls (110 lb.).....	lb.	55	55
Salicylic acid, U. S. P.....	lb.	90	95
Solvent naphtha, water-white, in drums, 100 gal.....	gal.	18	24
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal.	26	33

Tolidine.....	lb.	\$1.70	\$2.50
Toluoline, mixed.....	lb.	.45	.55
Toluol, in tank cars.....	gal.	.26	.30
Toluol, in drums.....	gal.	.27	.30
Xylylene, drums, 100 gal.....	lb.	.44	.50
Xylol, pure, in drums.....	gal.	.37	.45
Xylol, pure, in tank cars.....	gal.	.35	.45
Xylol, commercial, in drums, 100 gal.....	gal.	.23	.27
Xylol, commercial, in tank cars.....	gal.	.22	

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow.....	lb.	\$0.41	\$0.43
Beeswax, refined, yellow.....	lb.	.48	.51
Beeswax, white pure.....	lb.	.65	.66
Carabaua, No. 1.....	lb.	.85	.86
Carabaua, No. 2, regular.....	lb.	.75	.78
Carabaua, No. 3, North Country.....	lb.	.46	.47
Japan.....	lb.	.195	.20
Paraffin wax, crude match wax (white) 105-110 m.p.....	lb.	.06	
Paraffin wax, crude, scale 124-126 m.p.....	lb.	.064	.07
Paraffin wax, refined, 118-120 m.p.....	lb.	.083	.09
Paraffin wax, refined, 128-130 m.p.....	lb.	.093	.093
Paraffin wax, refined, 133-135 m.p.....	lb.	.11	.113
Paraffin wax, refined, 135-137 m.p.....	lb.	.12	.131
Stearic acid, single pressed.....	lb.	.23	.26
Stearic acid, double pressed.....	lb.	.28	.29
Stearic acid, triple pressed.....	lb.	.32	.33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal.	\$1.10	
Pine oil, pure, dist. dist.....	gal.	.96	
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal.	.45	
Pine tar oil, double ref., sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal.	.34	
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal.	.65	
Pine tar, ref., thin, sp. gr. 1.080-1.090.....	gal.	.38	
Turpentine, crude, sp. gr. 0.900-0.970.....	gal.	.83	
Hardwood oil, f. b. Mich., sp. gr. 0.960-0.990.....	gal.	.30	
Finewood creosote, ref.....	gal.	.48	

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....	280 lb.	\$17.50	\$17.80
Rosin E-F.....	280 lb.	17.75	20.00
Rosin K-N.....	280 lb.	21.50	22.75
Rosin W. G. W. W.....	280 lb.	23.25	24.50
Wood rosin, bbl.....	280 lb.	17.00	17.50
Spirits of turpentine.....	gal.	1.70	
Wood turpentine, steam dist.....	gal.	1.50	
Wood turpentine, dist. dist.....	gal.	1.48	
Pine tar pitch, bbl.....	100 lb.	8.50	
Tar, kilm burned, bbl (500 lb.).....	bbl	14.00	14.75
Retort tar, bbl.....	280 lb.	15.00	
Rosin oil, first run.....	gal.	.86	.91
Rosin oil, second run.....	gal.	.98	
Rosin oil, third run.....	gal.	.95	1.10
Rosin oil, fourth run.....	gal.	1.05	1.15

Solvents

73-76 deg., steel bbls (85 lb.).....	gal.	\$0.333	
70-72 deg., steel bbls (85 lb.).....	gal.	.311	
68-70 deg., steel bbls (85 lb.).....	gal.	.304	
V. M. and P. naphtha, steel bbls (85 lb.).....	gal.	.303	

Crude Rubber

Para—Upriver fine.....	lb.	\$0.504	\$0.51
Upriver coarse.....	lb.	.341	.35
Upriver cauchou ball.....	lb.	.321	.334
Plantation—First latex crude.....	lb.	.52	.57
Ribbed smoked sheets.....	lb.	.52	.57
Brown crepe, thin, clean.....	lb.	.471	.48
Amber crepe No. 1.....	lb.	.501	.51

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls.....	lb.	\$0.181	\$0.19
Castor oil, AA, in bbls.....	lb.	.211	.22
China wood oil, in bbls.....	lb.	.221	.23
Cocanut oil, Ceylon grade, in bbls.....	lb.	.171	.18
Cocanut oil, Cochiti grade, in bbls.....	lb.	.191	.20
Corn oil, crude, in bbls.....	lb.	.181	.184
Cottonseed oil, crude (f.o.b. Ill.).....	lb.	.181	.184
Cottonseed oil, summer yellow.....	lb.	.231	.24
Cottonseed oil, winter yellow.....	lb.	.241	.25
Linseed oil, raw, car lots.....	gal.	.701	.71
Linseed oil, raw, tank cars.....	gal.	.711	.72
Linseed oil, boiled, car lots.....	gal.	.751	.77
Olive oil, commercial.....	gal.	2.50	2.80
Palm, Lagos.....	lb.	.171	.171
Palm, bright red.....	lb.	.161	.171
Palm, Niger.....	lb.	.161	.18
Peanut oil, crude, tank cars (f.o.b. Ind.).....	lb.	.221	.231
Peanut oil, refined, in bbls.....	lb.	.241	.25
Rapeseed oil, refined, in bbls.....	lb.	.501	.51
Rapeseed oil, blown, in bbls.....	gal.	1.67	1.70
Soya bean oil (Manichuan), in bbls., N. Y.....	lb.	.171	.181
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.151	.151

FISH

Winter pressed Menhaden.....	gal.	\$1.70	
Yellow bleached Menhaden.....	gal.	1.23	
White bleached Menhaden.....	gal.	1.25	
Blown Menhaden.....	gal.	1.30	

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barrytes, domestic, white, floated.....	ton	\$35.00	\$40.00
Barrytes, off color.....	ton	20.00	25.00
Blanc fixe, dry.....	ton	.021	.04
Blanc fixe, pulp.....	ton	.47	.50
Cascan.....	lb.	.16	.18
Chalk, English, extra light.....	lb.	.05	.07
Chalk, English, light.....	lb.	.041	.06

Chalk, English, dense.....	lb.		\$.05
China clay (Kaolin), imported, lump.....	ton	25.00	35.00
China clay (Kaolin), imported, powdered.....	ton	30.00	60.00
China clay (Kaolin), domestic, lump.....	ton	10.00	20.00
China clay (Kaolin), domestic, powdered.....	ton	25.00	40.00
Fel spar.....	ton	12.50	17.00
Fluorspar, acid grade, lump, f.o.b. mines.....	net ton	30.00	35.00
Fluorspar, acid grade, ground, f.o.b. mines.....	net ton	35.00	45.00
Fuller's earth, domestic, powdered.....	ton	25.00	30.00
Fuller's earth, imported, powdered.....	ton	35.00	40.00
Pumice stone, imported.....	lb.	.03	.06
Pumice stone, domestic.....	lb.	.021	
Shells, TN.....	lb.	1.10	1.15
Shells, D. C.....	lb.		
Shells, V. S. O.....	lb.		
Shells, Diamond I.....	lb.		
Shells, orange, fine.....	lb.	1.25	
Shells, orange, superfine.....	lb.	1.20	1.30
Shells, A. C. garret.....	lb.	1.00	
Shells, bleached, bone dry.....	lb.	1.35	
Shells, bleached, fresh ground.....	lb.	1.10	
Sonstone.....	ton	15.00	25.00
Talc, domestic.....	ton	16.00	60.00
Talc, imported.....	ton	60.00	70.00

Refractories

Following prices are f.o.b. works:

Chrome brick.....	net ton	80-90 at Chester, Penn.
Chrome cement.....	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay.....	1,000	35-45 at Clearfield, Penn.
Clay brick, 2nd quality.....	1,000	30-35 at Clearfield, Penn.
Magnesite, dead, 100 lb. bag.....	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2 in.....	1,000	80-90 at Chester, Penn.
Silica brick.....	1,000	41-45 at Mt Union, Penn.

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon.....	lb.	.25	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon.....	lb.	.70	
Ferro-manganese, 70-80% Mn.....	gross ton	110.00	115.00
Spiegeleisen, 16-20% Mn.....	gross ton	33.00	36.00
Ferro-nickel, 50% Ni.....	gross ton	85.00	95.00
Ferro-silicon, 50% Si.....	gross ton	150.00	175.00
Ferro-silicon, 10-15% Si.....	gross ton	45.00	60.00
Ferro-tungsten, 70-80% per lb. of contained W.....	lb.	1.75	1.40
Ferro-uranium, 35-50% of U.....	lb.	7.00	
Ferro-vanadium, 30-40% per lb. of contained V.....	lb.	5.50	7.00

Ores and Semi-finished Products

Chrome ore, 35-40% Cr ₂ O ₃	unit	\$0.60	\$0.80
Chrome ore, 48% and over.....	unit	.90	1.00
Coke, foundry, f.o.b. ovens.....	unit	7.00	7.45
Coke, furnace, f.o.b. ovens.....	net ton	6.00	6.50
Petroleum coke, refinery, Atlantic seaboard.....	net ton	12.00	12.50
Fluorspar, gravel, f.o.b. mines.....	net ton		25.00
Manganese ore, 45% Mn and over.....	unit	.50	.75
Manganese ore, chemical (MnO ₂).....	gross ton	60.00	70.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂	lb.	.75	.85
Tungsten, Scheelite, 60% WO ₃ and over, per unit of WO ₃	unit	9.00	15.00
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃	unit	7.50	10.00
Uranium oxide, 96%.....	lb.	2.75	3.00
Vanadium pentoxide, 99%.....	lb.	6.00	
Pyrites, foreign, lump.....	unit	.17	
Pyrites, foreign, fine.....	unit	.17	
Pyrites, domestic, fine.....	unit	.16	1.71
Limonite, 32% TiO ₂	unit	.20	
Rutile, 95% TiO ₂	lb.	.11	
Carnotite, minimum 25% U ₃ O ₈ , per lb. of U ₃ O ₈	lb.	2.75	3.00
Zircon, washed, iron free.....	lb.	.10	
Monazite, per unit of ThO ₂	unit	42.00	

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags.....	bbl.	\$2.80	
Pump line, common, including container.....	300 bbl.	2.09	
Common brick, at dock.....	M.	16.00	
Yellow pine, 3x4 to 8x8, 20 ft. and under.....	M.	48.00	
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago.....	M.	50.00	
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis.....	M.	40.00	
Roofing, tar felt (14 lb. per 100 sq ft.).....	ton	70.00	
Roofing, tar pitch (in 400-lb. bbl.) carlots.....	ton	21.00	
Roofing, asphalt felt carlots.....	ton	34.00	
Roofing, asphalt felt carlots.....	ton	63.00	
Roofing, slate-surfaced, per roll of 108 sq ft. carlots.....	lb.	2.25	
Roofing, slate-finished shingles, 100 sq ft. carlots.....	gal.	6.00	
Linseed oil, raw in barrels.....	gal.	1.90	
Linseed oil, 2 gal. cans.....	lb.	.13	
Red lead, dry, 100 lb. keg.....	lb.	.144	
Red lead, in oil, 100 lb. keg.....	lb.	.161	
Red lead, dry, 5 lb. cans.....	lb.	.75	
Red lead, in oil, 5 lb. cans.....	lb.	.161	
White lead, dry and in oil, 100 lb. keg.....	lb.	.131	
White lead, dry and in oil, 25 and 50 lb. kegs.....	lb.	.131	
White lead, dry and in oil, 5 lb. cans.....	lb.	.15	

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45
Angles, 3 to 6-in., 1-in. thick.....	100 lb.	2.45
I-beams, 3-in. and larger.....	100 lb.	2.45
Plates.....	100 lb.	2.66
Rivets, structural, 1-in. and larger.....	100 lb.	4.20
Rivets, common, for boilers, 1-in. and larger.....	100 lb.	4.30
Sheets, No. 28 black.....	100 lb.	4.35
Sheets, No. 10 blue annealed.....	100 lb.	3.55
Sheets, No. 28 galvanized.....	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

Number 12

A Second Double Issue

EDITORIAL announcement was made in the last number of CHEMICAL & METALLURGICAL ENGINEERING of the general plan we intended to follow in printing issues delayed by the late unfortunate pressmen's strike. In pursuance of this policy, this second double issue is in your hands, Volume 21, Number 12, dated November 12 and November 19, but published December 13 *with current news*. Note particularly the last clause; editorial and market pages were closed two days before actual date of publication, and therefore contain material as fresh and readable as though we had never locked horns with the radicals.

Market letters perforce must cover the week ending December 6, while price lists cover the opening on December 8. With an interval between printings of less than a week, the time elapsing between gathering market news and placing it in your hands will quickly be reduced to the interval required by our regular routine.

The President's New Labor Conference

MANY apparently sage observations are made because they will "take" rather than because they are accurate. It has been a habit to assert that improvements can be made in an industry only by those engaged in the industry, despite the fact that many brilliant exceptions could be cited. There has been a disposition to assume that the capital and labor problem could be solved only by the parties getting together. Now the first industrial or labor conference called by President WILSON was marked at the outset to fail in meeting even that requirement, for it did not bring employers and employees together. It brought together representatives of employers, of the public and of labor organizations.

The second conference called by President WILSON avoids representation of either employers or employees as such. It would be the style of some people to say that the second conference is composed largely of "doctrinaires" or "dilettantes," but one can cast a slur upon almost any man or class of men if his hearers are receptive. One might better say that the new conference has in its personnel lawyers, politicians, school masters, even a food administrator.

Actually, the problem is largely psychological. Time after time it has been reiterated, and undoubtedly with truth, that it is not simply wages and hours of labor that are the issue with workmen who are dissatisfied. What, then, will satisfy the workman? At the first conference a strong address was made by one represent-

ative, who pointed out among other things that a workman could not be contented if he knew that he were merely a number on a payroll. That is true, but can he have the contentment that produces the best economic results if he knows merely that he is a certain number on the list of members of a labor union? If he is a union man all he can hope for is the things that unions are fitted to furnish, these being two, higher wages and shorter hours, good things in moderation, but, like many others, vicious in excess. Unions are not fitted to produce individual efficiency among their men, they have no system whereby they can secure a greater reward for the member who does better work than other members.

Granted that it is a psychological problem, it can perhaps be attacked better by men who are on the outside but have means of looking at the inside. Many of the members of the second labor conference are readily recognized as men who have a keen insight into human nature, and are presumably able to understand the operations both of the mind of the employer and of the mind of the employed. Given now the assistance of expert investigators and ample time for careful consideration, the chances are good that this conference can lay down a set of eminently fair principles, basic in their relation to the problem and harmonizing with the principles of political economy underlying our republic.

There is one item, in addition, that is very plain. The people of the United States do not want this matter settled by any method except one that will benefit the entire public. The public insists that a question of economics is involved. There are many ways by which differences between employers and employed can be settled to the satisfaction of those two parties, but to great injury to bystanders. The second labor conference at least will be much more disposed by its very constitution to consider the economics of the matter than was the first conference.

Lest We Forget Our Soldier Chemists

A YEAR has passed since the signing of the Armistice and the majority of those who have followed with interest the progress of demobilization undoubtedly feel that the re-assimilation of the discharged soldiers by the industries is now practically complete. While this may be true of industry as a whole, a recent interview with Major F. M. CROSSETT of the Relations Section of the Chemical Warfare Service brought forth the fact that a large number of technical men (the majority of them discharged) are still looking to the Relations Section for aid in securing positions commensurate with their training and experience.

Major CROSSETT's appeal to employers in need of men

with chemical or technical knowledge and experience will be found on another page of this issue.

Recalling the sacrifices made by these men in the service of their country, what is more fitting than that they should receive preference when positions in the chemical field are to be filled?

Union of

Thinkers and Workers

IN NOTING the rapid recovery of German business since the Armistice we are reminded of the remark of GLADSTONE to the effect that if hard work is not genius it's a mighty good substitute for it. While experience has taught us to discount largely all varieties of German propaganda, we must not underestimate the achievements of this nation gained through continual effort of its individual citizens.

We are told that the Leipsic Fair of 1919 had the products of 10,000 firms on exhibit and a record attendance of 118,000 persons. Among this number were 7000 foreign buyers. The manufacturers had ready for the market machine tools, agricultural machinery, porcelain and crockery, substitute products such as paper carpets, rugs and table cloths, and jewelry. Prices were from 200 to 400 per cent higher than before the war. A rather hopeless tone existed on the raw materials situation, markedly as regards coal, many plants being idle on account of this shortage of supplies. The chemical works are said to be operating on three shifts daily.

The German people realize that only work can save them. Work is essential to the progress of any nation or individual. But how much better is the combination of work and genius! What heights may not be attained!

The American is by nature ingenious. He is also a worker. But for the happiness of each of us and the progress of all, *the worker must work*, and use his head betimes. The incentive is still there, and when he stops to think about it, he will realize the tremendous things in store for this union of thinkers and workers.

Labor-Saving Machinery

In Iron and Steel Industry

THE shortage of common labor in the United States produced by the almost complete absence of immigration for more than five years has naturally directed attention afresh to the matter of the much-mentioned "labor-saving machinery." The iron and steel industry has been seen to employ large numbers of "common laborers," and so one easily jumps to the conclusion that the industry ought now to adopt more labor-saving machinery if indeed it has not been remiss in past years in that respect.

There is nothing in such a conclusion, however, unless it will stand reasonable scrutiny in the light of quantitative facts. It is true the industry employs a large quantity of common labor (not regarding labor as "a mere commodity," of course—it is only the labor unions that want to make it simply a commodity), but the industry is a very large industry. The common labor employed is small relative to the tonnage. Last year was an off year for results, and the 1917 figures of the United States Steel Corporation, the best index that can be used, showed 268,058 persons employed, on an average, with an output of about 14,500,000 gross tons of all steel products. That

was just 50 gross tons per person per year. The employment began with the mining of coking coal, as well as a little steam and gas coal, the mining of iron ore and the quarrying of limestone. In included much transportation service and wound up with the shipment of much finely finished material such as wire nails, tin plate and formed sheet products, including all office work. If 35 pounds per day of the average steel products is not much of an undertaking, try it yourself, starting with the coal, limestone and ore in the ground, remembering that you must also sell the material and collect the money for it. The weight of material handled or processed is much greater, and if the weights involved in each operation were added the total would be stupendous. In a great many cases one man is responsible for several tons of material a day going through an operation, and in some instances one man is responsible for hundreds of tons.

From this quantitative viewpoint one discovers a paradox, but at once sees through it, that the employment of labor-saving machinery actually produces the need for a great deal of common labor. The machinery does so much work that the odds and ends left for common labor to do are great relative to the total number of men employed. By no means, moreover, is it always a case of machinery plus the skilled men to operate it replacing a large number of common laborers. For instance, if merchant steel bars were not rolled in practically automatic machinery very large numbers of skilled men would be required to roll the bars. One does not need to depend upon imagination or history to indicate this, for he can see the object lesson in the iron-rolling mill, iron being less susceptible than steel to automatic manipulation. Then, too, there are many instances of the machinery being so automatic that it is a common laborer who operates it. The so-called "common labor" is quite far from being confined to wielding the pick and shovel and pushing the wheelbarrow.

Another means of illustrating the fact that the common labor employed in the iron and steel industry is very small proportionately to the total results accomplished is to point out that if there were no labor-saving machinery millions and millions of men, a number incalculable, would be required, instead of a few hundred thousand. Considering the development of the industry in the past few decades, one is tempted to wander off into a speculation as to how many men the United States or any other country could afford to employ in producing steel. Possibly if it took twice as many men to produce a ton of steel we should have to get along with half as many tons. In other words, there might be more or less of a tendency, in any country, to employ a certain percentage of the population in making steel, whether the output per man were large or small.

In this matter of replacing labor by machinery there is too much disposition to look backward and assume that the remarkable achievements of the past in introducing machinery need simply to be continued. A very great deal of the work has been done. There is more to be gained by looking in other directions, and considering the economic and financial factors. These have a great bearing upon the matter. The workman has been employed when there is work and has been dismissed when there is

none. With machinery capital has been invested and with idleness there is amortization and loss of interest.

If industry were established so that machinery could be kept in steady employment, there would be more machinery used. The man who attended the machinery and worked with it would likewise have steady employment. The change cannot be made suddenly, but there can be progress in that direction, and on the whole there probably is progress. When steel prices are kept from dropping below cost, including liberal overhead, and from advancing to discouraging heights, much progress is made. When money is made more uniformly available, as by the Federal Reserve banking system, the disposition of men to buy much steel in one year and little steel in another is reduced. Improvements like this tend greatly to encourage the installation of labor-saving machinery.

The Cost-Plus Contract In Future Construction Work

THE necessity of finishing the plant and getting it into operation for the production of war material and supplies, regardless of the cost, has brought into prominence the cost-plus-fixed-fee type of contract. Competitive bids were not to be considered on erection of Government plants because the work had to be started before specifications were completed. It was also impossible for private concerns to gamble with the Government for the high stakes involved and during a period of wildly fluctuating markets.

This system of fees has worked out so well for the contractor that it is being generally advocated by individuals and corporations engaged on construction work, and the prospective owners of new works are being confronted with requests for its adoption in all lines where contract is required.

The contractor claims that the cost-plus-a-fixed-fee contract or the cost-plus-a-sliding-fee contract has, among other advantages over the competitive bid, the following: First, it eliminates the element of chance or gamble between owner and contractor; either may lose under competitive bid system; second, work may be started before the plans are completed, hastening completion date and putting the owner's capital to work the more quickly; third, it prevents the many failures of contracting firms; these operate to owner's loss when occurring during the construction period; fourth, the arrangement is fairer to both parties: when saving is effected, both may profit, the owner to the greater extent.

The contractor is perhaps justified in these arguments, the theories seem sound and the employment of this contract is advisable with certain limitations.

The application is practical where the parties at interest are straightforward, conscientious concerns. Universal peace, socialism, pure democracy, free trade, golden rule and all other beautiful theories would also be perfectly practical were all men alive to moral obligations toward others and prepared for the long-expected millennium. But just as the banker must be wary of the occasional dishonest customer, so must the "shrewd business man" be watched. Otherwise contracts would need to exist only as records of requirements and not as binding legal agreements. The most ardent supporters of the cost-plus contract admit the opportunity for dishonesty and admonish owners to seek honest contractors.

It is generally known that a substantial majority of cost-plus contracts executed by the Government did not operate to its advantage, nor yet with fairness to this party of the first part. The incentive to the contractor to perform the work in the most efficient manner was not present; in fact, the contrary was true. Many men of the service now in private life have seen the contractors, and large concerns at that, carelessly waste millions of dollars from the public fund, provided for war purposes, on cost-plus contracts. They have seen workmen employed by these contractors either criminally idle at their jobs, or drawing pay without assignment to work. The driving force was lacking because there was no incentive to create it.

Pleasure automobiles, unnecessary to the work, and living quarters, luxurious beyond all reason, have been furnished their overpaid officials at Government expense. At the time when there was the noble thought of patriotic endeavor to hold them "square" it was considered quite the thing to be careless of public money. Carelessness permeated their entire organizations.

It has been said that losses on war contracts were due to inefficiency of the workman. The truth in most instances was not that he could not do the work, but that he would not do the work. There was no driving force to compel him to work, either in the form of exhortation, fear of losing his job or hope of reward. The contractor did not provide this force as he certainly would had his own dollars been in jeopardy.

This hyphenated contract throws all responsibility on the owner. A contractor is ordinarily retained to do the work because he supposedly has expert knowledge of conditions surrounding the labor and material markets. That's his business, and if he's a real contractor he should be willing to stand on his knowledge of the business. War markets are the exception, of course, but he certainly has no cause to complain on that score. The owner pays him for taking the responsibility and therefore does not expect to do the work for him.

In any type of contract the owner must see that the terms are carried out as intended. On fixed bid agreements this takes the form of an inspection of material and quality of workmanship. On cost-plus contracts the feature of labor efficiency and methods is an added burden and the owner must supervise as well as inspect. This supervision if properly carried out in many cases calls for an organization parallel to and nearly as large as the contractor's overhead construction force. The owner might as well do his own work.

With numerous examples of losses on cost-plus contracts at hand the owner must, then, consider carefully. If he does not have a force of his own available for adequate inspection and the added feature of supervision, he must retain the services of a strictly professional consulting engineering firm, not engaged in the sales or contracting business, which he can rely upon to handle to his best interests. This applies to the smallest contracts.

The cost-plus contract may be the forerunner of a type that makes for a distinct advance in business methods. It would be well, instead of discussing hyphenated terminology, for the contractors' associations to submit some standard detailed forms of this new type. Certainly the war-time cost-plus variety will never be satisfactory to the private owner.

Senate Bill 2715, 66th Congress

To the Editor of Chemical & Metallurgical Engineering

SIR: The above bill for the reorganization of the Army stipulates that the Chemical Warfare Service be made a subsidiary branch of the Corps of Engineers of the U. S. Army. It is my sincere belief that this provision will make the United States defenseless against any enemy in war that adopts the use of chemical warfare, whether in breach of convention or otherwise. For the distant future the bill makes provision for a great institute of research, which is to be under the jurisdiction of the same corps, and is to encourage men of the greatest scientific attainment in the country to co-operate with the Army. For the immediate future, however, I am under the impression that if the little that remains of the Chemical Warfare Service be joined to the Engineers Corps it will cease to function to good effect. Chemical research cannot be prosecuted in company formation, or under military rule, and even its progress is likely to be invisible, except to the chemically trained mind. The science requires the individual time and attention of him who follows it, and it is in no sense a side issue to be mastered as an incidental study, either at West Point or anywhere else. We have suffered amazing wastes during the war owing to the lack of understanding of chemical reactions by men in authority, and I hold that this branch of the Service, whether gas warfare be forbidden by convention or not, should be constantly maintained, under competent direction, as a measure of national safety. In times of peace the Corps of Engineers is usually engaged in connection with public waterways, or other Federal engineering undertakings, and it stands to reason that the Chief of the Division of Engineers is likely to assign his least useful engineer officers to the supervision of this branch of the Service which, by its very nature, cannot show any good results.

Defensive chemical warfare cannot be studied without equal diligence addressed to the discovery of means of offense. I therefore make bold to urge that the Chemical Warfare Service of the Army be made a separate and distinct branch of the Service, instead of being a department of the Corps of Engineers as provided for in the above-mentioned bill. C. W. S.

New York City.

An Alloy Which Resists Molten Brass and Bronze

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the Aug. 1 issue of CHEMICAL & METALLURGICAL ENGINEERING there appeared a very live editorial on the subject of "Pyrometers for Brass and Bronze Makers." In that editorial you make one statement, however, which I think is apt to be misleading. The sentence I refer to reads: "An alloy of 25 per cent chromium and 75 per cent iron can be cast into moderately thin tubes, but corrodes in rather an erratic manner."

The alloy to which you refer is manufactured by us and is known as Chromon. It is being used as a protective sheath for thermocouples in measuring the temperatures of molten brass and bronze mixtures. Your statement that the alloy's behavior is erratic is true

only when the equipment with which the alloy is used is misapplied. The alloy is rapidly attacked by high-phosphorus bronzes, nor does it give uniformly good service at temperatures above 2200 deg. F. A pyrometer outfit which we sell for this purpose is intended for intermittent use; that is, the protective tip should not be immersed permanently in the molten brass. Used intermittently, most of our users are getting approximately 150 readings before a renewal of the protective tip is required. The brass manufacturers seem to consider this very good service and certainly it allows the measurement of temperatures of molten brass to be made more economically than by any other known method. Of course, it would be ideal if it were possible to use a thermocouple which did not require protection and which could be inserted directly into the molten metal. The well known Chromel thermocouples which we manufacture are probably as resistant to this action as any other alloys, yet it is very unsatisfactory to try to use them without any sort of protection.

Readings can be taken in about ninety seconds or quicker if the protective tip is not cooled off entirely. It is often found not necessary to check every ladle and some users prefer to check only when changing to a different alloy or to a different casting. For instance, the proper pouring temperature can be determined for a certain job, and after the first few ladles are checked, and the job is going well, it is necessary to measure only the temperature of every third ladle. It is entirely possible to hold a ladle of brass long enough to take the temperature, and it just as often happens that the metal will be found too hot rather than too cold. One ladle cast at the wrong temperature, at least on certain jobs, will pay for the cost of making a very large number of temperature readings on castings poured at the right temperature.

These comments are presented, not to criticize the editor for holding high ideals, because we appreciate that he is in a position to state the needs of the art and that he has done so very clearly and well. However, we believe that the temperature of molten brass can be satisfactorily determined day in and day out with the help of this Chromon alloy, and, barring the usual opposition to innovations in the foundry business, it is being done to the decided advantage, both of the piece worker and the manager.

Tests at Watertown Arsenal

Testing of materials for industrial purposes at the Watertown Arsenal showed very large increase during the fiscal year ended June 30, 1919. Development has been carried out not only along metallurgical lines, but in all phases of work, including the development of cutting oils and the examination of quenching media. During the fiscal year the total number of specimens tested was 43,964. This is an increase of 259 per cent over the work done during the preceding fiscal year. The total number of chemical analyses for the fiscal year ended June 30 was 48,339. This was an increase of 522 per cent over the figures of the preceding fiscal year.

Western Chemical and Metallurgical Field

Details of Anaconda's Chimney

ANACONDA'S newest "big stack," with its smoke purification system, went into service during the summer, giving the expected clearance almost from the start. A brief description of this largest project in dust collection was given in our issue of April 15, 1918 (Vol. 18, p. 392), and the accompanying drawings of the chimney more recently appeared in *Engineering News-Record*, for Oct. 23, 1919 (Vol. 83, p. 764), by courtesy of the Alphons Custodis Chimney Construction Co., the designer and builder.

Little can be added to the details given on the drawings. As shown in the drawing and in the accompanying view of the base of the Anaconda chimney, the concrete base is octagonal in shape, 89 ft. outside top diameter and from 10 to 30 ft. above the ground. On it an octagonal brick section 86 ft. in diameter and 68 ft. high carries the circular tapering brick chimney, rising as shown to a total height of 555 ft. The main shaft has five different tapers, and the thickness varies from 58 in. at the top of the octagonal section to 22½ in. at the top, under the terra cotta cap. The concrete base reaches down to a good rock foundation, with a load of about 7.5 tons per square foot.

Fine clay-like flotation tailings mixed with coarser table-tailings sand was used for making the brick. In order to handle this job, the brick department was moved from the west end of the town to the flat alongside the slime pounds, there to be near the source of brick-making materials and point of consumption. Mod-

DETAILS OF FOUNDATION FOR WASHOE CHIMNEY

GENERAL DETAILS OF HIGH BRICK CHIMNEY FOR WASHOE SMELTER AT ANACONDA

ern machinery was installed and the brick burned at about 1800 deg. F. (1000 deg. C.) in a continuous kiln. About 17,000 tons of radial perforated blocks were used in the chimney proper. Acid-proof mortar made of lime-free materials required 10,350 bbl. of portland cement, 1850 tons of fire clay and 2700 cu.yd. of siliceous sand; 1:3:5 concrete was used in the foundation.

The annexed table gives some general details of the two "big stacks" at Anaconda, together with other notable chimneys built in the West in recent years, whereby some idea of the comparative size of modern stacks may be had. In 1903 the 300-ft. brick stack at Anaconda, standing on a hill behind the new Washoe plant, was one of the seven wonders of the smelting world! Tacoma has the palm for extreme height, but none of the others approach the bulk of the 506-ft.

TABLE I—DATA ON RECENT NOTABLE CHIMNEYS

Plant	Year	Clear Inside Diameter		Wall Thickness		Height Above Foundation	Material
		Top	Bottom	Top	Bottom		
		Inches	Inches	Inches	Inches	Ft.	
Anacosta	1903	30 ft.	31 ft., 4 in.	12½	62½	300	Common brick
Anacosta	1918	60 ft.	76 ft.	22½	64	555	Radial blocks
Great Falls	1908	50 ft.	66 ft., 6 in.	18½	66½	506	Radial blocks
El Paso	1917	30 ft.	34 ft., 6 in.	13	38½	400	Common brick base 80 ft. high and radial brick columns
Helena	1917	16 ft.	25 ft.	11½	40	400	Anacosta radial brick
Tacoma	1917	23 ft., 11 in.	39 ft.	13½	61½	571	Paving block brick
Murray	1917	19 ft., 9 in.	38 ft., 9 in.	7	291	570	Radial brick
Sachsewski	1917	26 ft., 3 in.	37 ft., 9 in.	7	291	570	Concrete

*Plus self-supporting lining 145 ft. high, 12½ in. thick at base, 8 in. thick at top.

†Plus 4-in. lining to top.

†Lined with 4-in. radial block for 125 ft.

chimney built at Great Falls in 1908, or the newer and larger one built ten years later at the other smelter of the Anaconda Copper Mining Co.

By-Product Tar as Open-Hearth Furnace Fuel

Two innovations in their regular open-hearth practice were made at the Minnequa plant of the Colorado Fuel & Iron Co. in 1918 and have been successfully maintained since that time, namely, the use of by-product tar as fuel, and of molten spiegel as a ladle addition. Frank Ferguson has described these improvements in a recent number of the company's organ, *Industrial Bulletin*, from which the following information is taken.

"The spiegel plant was put into operation on Aug. 5, 1918, it being the third installation of its kind in this country. The basic idea of the process is to melt down an alloy of a constant chemical analysis that is carried into the open-hearth pit in a molten state and added to the steel as it runs into the steel ladle from the furnace proper, thereby practically eliminating the production of 'off-grade' high carbon in rail heats, and making for a more uniform manganese in the finished steel and less variation in both the carbon and manganese from heat to heat.

"It is also more economical and has increased the efficiency of rail-melting practice fully 10 per cent, the month of April of this year being the best month the department ever had on rail steel, when it made 93 per cent good rail heats.

"The use of tar in the open-hearth furnaces went into effect July 18, 1918. As a comparison between gas and tar, producer gas comes into the furnace as a big, full bodied flame by the pull of the stack on 40 to 60 lb. of steam pressure at the gas house, while tar makes a thin, light flame delivered into the furnaces under terrific pressure. The tar comes through the lines at 80-lb. pressure, while at the furnace where the tar goes into the burner or 'gun' it is broken up under 50-lb. steam pressure.

"Tar makes a much hotter flame than producer gas, therefore the tonnage is increased, but being so much hotter than gas, the furnace burns out quicker. From an economical standpoint, the comparison of one tar furnace and one gas furnace shows that the advantage is slightly in favor of the tar furnace.

"The main advantage of tar is in using it on the furnaces every week when the gas sewers are burned out, thereby keeping it in operation instead of shutting down for 12 hours once a week; also in using it on a furnace that it is impossible to run with gas. As an illustration, a short time ago the south end of No. 11 furnace fell in, completely blocking the slag pockets and checker-chambers, making it impossible to run the furnace under those conditions with gas. Tar was put in the furnace and it ran three weeks and four days and made comparatively good time."

Present Strength of Chemical Warfare Service

In announcing the allotment of the funds carried by the Army Appropriation bill for the current fiscal year, the Secretary of War has designated 124 officers and 1348 enlisted men as the strength of the Chemical Warfare Service for the fiscal year.

The Laboring Man and the Mails

WE PRINT elsewhere in this issue an address by a Senator on the postal-zone system. We do not want to weary our readers on this subject, and we have refrained from discussing it more frequently, solely because it might seem that our own interest is more immediate and pressing than that of our subscribers. At the same time we believe that the ultimate effect of this restriction on the use of the mails will be far more harmful to the people at large than to the publishers of periodicals. Let us study the question.

In our issue of Sept. 15, we gave a record of a visit to Newark and a report of the work on Americanization undertaken by the manufacturers of the so-called Iron-bound district. There and elsewhere it has been discovered that a vast number of foreigners who can neither read nor speak English get anarchistic papers printed in their own language, and that this Bolshevik propaganda is the only newspaper or periodical literature they are able to read at all. The publishers of such papers do not register them as second class matter; they distribute them secretly because the mails are not open to the advocacy of arson and rapine and murder—which is the very substance of the doctrines of the Reds.

DUTY TO FOREIGN RESIDENTS NEGLECTED

We believe that as a people we have neglected our duty in regard to foreign residents. We have left them alone when we should not have done so; we have neglected these smoldering fires until now they threaten to break out in a social conflagration. An observing man of our acquaintance has been wandering about the East Side of New York of late, and every night at one place or another he hears the gospel preached that capital and labor are at enmity and cannot work together for the common good; that our government, laws and institutions are all capitalistic and consequently wrong; that the ballot has lost its potency, and that its only usefulness is to elect revolutionists, who will preach the doctrine of anarchy until the day for the break-up of government and order shall be at hand. And nobody takes the trouble to contradict it! We accept our share of the blame for this, for we are all blameworthy. It is time for us to get busy and put out the fire; and it cannot be done by means of policemen. We must come back at our erring neighbors with arguments more effective than Thou Shalt Steal, and Thou Shalt Kill. We must do it in languages that very few of us can speak, and it must be done chiefly through the mails.

To those of us who have ever attended a Left-Wing Socialist meeting and compared it to a regular Republican or Democratic Campaign Hurrah, the result is humiliating. These anarchists of one phase or another are many of them sincere, and many truly believe that the destruction of all governments such as we have is the true way of betterment. Others who can't get ahead or who have got themselves in wrong expect to be leaders or dictators in disorder. They abide in darkness for their own profit. But all use their minds at these meetings, and use them with an astuteness that would confound a seasoned old campaigner in five minutes. There's no use in getting angry over it, because the price of anger is failure.

Now let us consider a few theories, a few facts, and possibly a few arguments connected with them, with a view to starting better trains of thought.

The Reds all hark back to Karl Marx in dividing the people of the civilized portions of the earth into two groups: the capitalists and the proletariat. Associated with the capitalists are the bourgeoisie who are classed with them. All wealth, they say, is produced by labor, and it is the proletariat who should enjoy it, because labor alone produces it. In a Socialist state, the proletariat, being in the majority, will rule, and the government will control production and distribution, in addition to its other functions. Socialists are divided between the Right Wing and the Left Wing, of which the former believe that the way to achieve the desired reforms is by the ballot and legislation. The Left Wing is the radical section, and believes that the desired reforms are only to be accomplished by revolution. The Communists are of the same opinion as the Left Wing.

PROLETARIAT AN INHARMONIOUS BODY

The proletariat, however, contains not only the ignorant, the inexperienced and the uneducated, but a vast majority of the feeble-minded. This fraction is so large as to make the proletariat an inharmonious body within its own ranks. It contains also many intelligent persons who want to get ahead and become men of circumstance. We may almost say that a majority of our best citizens who have achieved recognition and affluence started as workers with their hands, and so come from the proletariat. It is no disgrace to be of it, or to work with our hands. And when we consider the scale of wages now current, it is a profitable thing to do. On the other hand, the feeble wits cannot even understand that it is not only unethical but unprofitable to break a contract. They are not even intelligent enough to keep a promise, whereas the man with a future before him wants to keep his record clean. These straightforward ambitious workers and the half-witted sloths never have got along together, they do not get along together now, they never can get along together, and they never will. There is intelligence of the highest order among the proletariat, but the average is too low for reasonable government by them. This is one of Marx's great errors. We can have revolution and anarchy and dictatorship following; but we cannot have intelligent rule or competent and proper supervision from the men and women who make up the proletariat today. The percentage of morons is too high. We need all the intelligence available in the election of representatives or members of soviets, or whatever we want to call our men and women to whom the administration of government is entrusted. We make some pretty bad mistakes as things are.

According to Professor Millekan, who quotes a progressive economist as his authority, if all the incomes in the United States were completely leveled, so that a hod-carrier and the president of the United States Steel Corporation received exactly the same wage, and all our millionaires received the same as these two and no more, the increase in the pay of the average worker would hardly rise above 10 per cent.

In this respect, also, the Reds are all wrong. Let us, for the sake of argument, grant them everything

they ask for, and imagine a government according to their own desires, and postulate the impossible, which is industry under Bolshevik rule and productive at the same time. Even then there would be no rich men's luxuries, such as expensive automobiles, grand pianos and the like, for the proletariat. The only person who could have them would be the few that they would elect to power and wealth. There's nothing of the sort for the common man in the Socialist state, and it would be harder to get elected than that it is now. A study of the telephone industry of the country brought out the fact that a similar leveling would increase the income of the wage earners by no more than from 2 to 3 per cent.

Let us borrow some more ideas from Professor Millekan in his address to the Summer School at Chicago this year. It has been generally admitted that the living conditions of the average American workingman and his family are better than the average living conditions of such men in Europe. This is not due to better distribution of wealth, because we have made a greater number of rich men here than any other country. It is due to the increased production of material per man here, because of great national resources and the use of labor-saving machinery; to geographical location, and to the inventions of single men. Look at such little things as the discovery of ductile tungsten, which makes electric light one-third as expensive as it was before! That was not accomplished by vote or by revolution. It was the work of very few men, and all are benefited by it. Most of our increase in wealth comes from just such single steps which cost great energy and labor to bring into general use, and which nobody will undertake unless he can get a reward for it. Distribution of wealth is a subject of vast importance, and things are not right as they are. The allotment is not fair in accordance with services rendered, but revolution and Bolshevik rule will not provide any improvement in the condition of the man who works with his hands. In fact, without the inventions and foresight and courage of our exceptional man he will not even have a job.

Now these vicious ideas that the road to independence and well-being is through theft and riot and murder are largely held by our foreign population who do not have the chance to read anything else. As for their American leaders, we are learning how to deal with them; but what the foreigners most need is enlightenment. They live in communities scattered all over the country. They can be reached by literature published in their own languages. The zone system of the post-office taxes this very effort.

The A. C. S. Chicago Section Directory

The Chicago Section of the American Chemical Society has published the 1919 Directory of Members—the largest yet issued. It contains a list of awards of the Willard Gibbs medals, the past officers of the section, a copy of the constitution and by-laws, a directory of the members with personal record opposite each name, and a classified index of members according to occupations and industries. The classified index as well as the personal records of the members is particularly complete. The booklet is a valuable aid to the industry in the Chicago district and an example by which the national societies may well profit.

Col. Joyes on Nitrogen-Fixation in Europe During the War

ONE of the most remarkable attainments of the war, according to Col. J. W. Joyes of the Nitrate Section of the Bureau of Ordnance, who recently returned from a trip to Europe with the United States Fixed Nitrogen Commission, was the development by the German Badische Anilin und Soda Fabrik of Prof. Haber's synthetic ammonia process. This was only one of the many interesting observations made by the Commission during its visit to France, the portion of Germany occupied by the Allies, England, Norway and Sweden. Much information has been brought back as to the development of the processes of fixation and as to the use of the several marketable products, especially in explosives manufacture and in the fertilizer industry.

The Badische Anilin und Soda Fabrik operated plants at Ludwigshaven and Merseburg. Concerning its development of the Haber process Col. Joyes says:

"This process involves a number of most interesting steps in chemical manufacture. The outline of the process is generally known as the production of a mixture in suitable proportions of nitrogen and hydrogen gases and the combination of these into ammonia. All chemists know the difficulties involved in the necessity for using a catalyst to stimulate the reaction, which even then must be at high pressure and temperature, and get commercial results, and the necessity for having the gas mixture most carefully purified in order to avoid poisoning the catalyst.

PLANTS RUN SUCCESSFULLY UNDER GOVERNMENT STIMULATION

"The Badische plant, existing on a small commercial scale at the commencement of the war, was greatly expanded under government stimulation when the probable inability to bring in enough Chilean nitrate for war needs became apparent.

"The plant at Ludwigshaven, which was visited by the Commission, was not in operation, but the Commission had an opportunity to get a fair general idea of its magnitude, of the difficulties encountered, and of the apparent success with which they had been met. As it stands, it is said to have a capacity of over 200 tons of ammonia per day, and has installations for using this to make nitric acid, sodium nitrate, and several other products useful in agriculture as fertilizers, and in munitions and other manufactures.

"The plant is reported to represent an investment of several hundred million marks of the Badische company's capital, and undoubtedly a substantial government subsidy. Notwithstanding the fact that the works give an impression of great complexity and therefore of large requirements in skilled and other labor for operation and maintenance, there is no doubt that whatever operating troubles occurred, and there must have been many, the plant did produce the much-needed ammonia. And if the statements made as to the writing off during the war of a substantial portion of the value of the plant be true, it must be credited with commercial success under conditions of war. How this and the smaller establishment at Merseburg will meet the competition of the future, with the accompanying high prices for materials and labor, of course remains to be seen."

Vigorous efforts are being made in France, the Commission found, to use cyanamide, as such, as a fertilizer. In that connection, Col. Joyes says:

CYANAMIDE AS A FERTILIZER IN FRANCE

"During the war a number of cyanamide plants were built or commenced in France by private corporations and by the government. Some of these were not finished at the time of the armistice and will not be available for production in the future, but there still remains in France a considerable increase in the capacity for manufacturing cyanamide due to the war. Prominent officials of the French Government are keenly alive to France's needs for a more efficient agricultural system using much more fertilizer than heretofore. There has been much effort to stimulate the use of fertilizer by pointing out its advantages and by scientific research and demonstration. Arrangements have been made for marketing a considerable quantity of the cyanamide produced by the French Government in order that this cheap nitrogen compound made available by the war shall not be lost to agriculture. Although some portion will be converted into the more popular form of ammonium sulphate, etc., vigorous efforts are being made to induce farmers to use the cyanamide as such on account of the great economy in so doing.

"For years Germany has been stimulating, by governmental research, demonstration and publications, the use of cyanamide itself as a fertilizer. These efforts did not cease during the war, but were continued, and it appears that they have had a marked effect inasmuch as the German farmers are using cyanamide for direct application to the soil to a considerable extent. Although many of Germany's cyanamide factories, the capacity of which was greatly increased during the war, are now idle for lack of raw materials principally, these factories remain available to produce a great quantity of this cheapest form of fixed nitrogen fertilizers."

PLANT DEVELOPMENT IN NORWAY

Development of Norsk-Hydro arc plants in Norway and in the Pyrenees called for particularly complimentary references from Col. Joyes. Concerning them he said:

"Especially interesting from a civil engineering standpoint were the water-power developments of the Norsk-Hydro arc plants at Rjukan, Norway, and of M. Ferdinand Gros in the Pyrenees Mountains in Southern France. In the former of these, water from a lake high in the mountains was used successively in two 100,000-kw. power plants, each with a head of 250 meters, and later in several other plants with lower heads. In the latter, M. Gros has tapped a lake in the Pyrenees fed by perpetual snow, and after successfully overcoming the difficulties of leading this water something over twenty miles through quite rough country, is able to use it with a head of about 800 meters, developing about 30,000 kw.

"M. Gros, a most progressive Frenchman, who has become noted for his introduction and production of liquid NO, during the war for use with benzene in air bombs, expects to use the Pyrenees power above mentioned in a new factory, now nearly completed, where he will make cyanamide for fertilizer use, and also other products."

Cynamide-producing capacity increased materially in Scandinavia during the war, the Commission found. Concerning their observations there, Col. Joyes says:

SCANDINAVIA'S INCREASED OUTPUT

"The plant of the Norsk-Hydro company's celebrated Birkeland-Eyde arc-fixation process was practically doubled in 1915-16. This plant makes calcium nitrate as its principal normal product, which is used in Norway especially as a fertilizer for direct application to the soil. It has also been sold during the war to munitions manufacturers. This plant was one of the most interesting seen on the trip, as it demonstrates on such a large scale how a process with an extremely low technical efficiency can, under favorable circumstances and with clever engineering, be made to yield a handsome profit. This plant has enormous capital invested with most advanced hydro-electric and electrochemical installations in substantial buildings of handsome and suitable design."

Valuable scientific research on the fixation problem was done in England during the war. If the war had continued, England would have constructed several establishments to use some of the available processes.

The Fixed Nitrogen Commission, which was charged with the duty of obtaining information as to the present state of nitrogen-fixation development in Europe, consisted of Col. J. W. Joyes, Ordnance Department, U. S. A., chairman; Lt. Col. A. B. Lamb, C. W. S.; Lt. Col. F. H. Wagner, Ordnance Department; and Capt. R. S. Tour, Ordnance Department.

de Fremenville on Mechanism of Fractures

At the 40th annual meeting of the American Society of Mechanical Engineers, held Dec. 4, in New York, Charles de Fremenville, consulting engineer to the Creusot Works, France, read a paper on the "Reliability of Materials and Mechanism of Fractures." He noted that the first motor cars were cumbersome, heavy contrivances, principally because they were made of ordinary carbon steels with usual factors of safety. The problem, then, was to replace heavy parts like gears or crank shafts, which were subjected to severe but normal work, and second, parts like axles and wheels which normally were stressed very slightly but may at any time be given severe shock. Such parts should better bend on overstrain than break, and the bending should be easily perceived and the part replaced.

Therefore, about 1901, various steel plants began production of alloy steels of high strength and which tested well under ordinary conditions. However, many puzzling failures were observed in service, not only of the new alloys, but many dangerous fractures of mild steels began to appear. Fremont's impact test, originally developed for soft materials, was therefore adapted to test hard metals, and this quick-bend test has since rendered service of extreme importance in eliminating unsafe metal from automotive construction.

Consideration of shock-fractured ductile metals revealed striking similarity to breaks in glass, quartz or bitumen. The last was particularly handy for experimental work, being easy to mold, when warm, into any required shape. In such media, illustrative breaks were shown by the speaker to develop quite symmetrically, fanning out from the first rupture in a definite pattern. Conversely, this "focus" of rupture, identified with the point which gave way first, could

easily be located by the convergence of the rays and surfaces of fracture.

Passing to the consideration of thick pieces of metal broken under impact, the focus of rupture is at the side opposite that receiving the blow, but strangely enough, at a material distance inside the surface of the piece, a fine silky area intervening. From this point the material apparently splits along a series of substantially smooth surfaces, sometimes overlapping, and sometimes separated by ripples which further out develop into major fracture planes.

Relations Section, Chemical Warfare Service

BY MAJOR FREDERICK M. CROSSETT

Many men are being discharged from the Army who before entering service were engaged in work requiring chemical or technical education and experience. Nearly all are college or technical school graduates with practical experience. They also have had the benefit of Army training and discipline and, in some instances, the handling of men, research work or chemical engineering. Some of them are anxious to secure employment.

To help them the Relations Section of the Chemical Warfare Service is acting as a clearing house. From the applicants (from all over the country) there is a rare opportunity to select splendid men of exceptional ability, who are well qualified to fill any place requiring chemical or technical knowledge and experience. Some seek places as executives, engineers, superintendents, plant operators, foremen, supervisors and salesmen.

When men are wanted preference should be shown those who have served their country in the war. Kindly employ and recommend them when opportunity occurs.

Do you need a man? If so, please send full details of your requirements. We have them from \$1200 to \$12,000 a year. A line to the Director of Chemical Warfare Service, Washington, D. C., will bring prompt attention.

Increased Cost of Printed Copies of Patents

The following notice has been received from the Commissioner of Patents:

H. R. 9205, a bill "making appropriation to supply deficiencies in appropriations for the fiscal year ending June 30, 1920," etc., which was approved Nov. 4, 1919, contains the following provision:

"That hereafter 10 cents per copy shall be charged for uncertified printed copies of specifications and drawings of patents."

The act of Feb. 20, 1905 (as amended), relating to the registration of trade-marks, provides in Sec. 14 that the fees shall be: "For certified and uncertified copies of certificates of registration and other papers, and for recording transfers and other papers, the same fees as required by law for such copies of patents and for recording assignments and other papers relating to patents."

You are therefore notified that this provision having become effective, the charge for printed copies of patents, trade-marks and designs shall be 10c. each.

Five-cent coupons will be accepted at their face value in payment for copies. In ordering a copy on five-cent coupons, it is only necessary to fill out one such coupon, the other being blank and used in lieu of cash.

House Passes Longworth Dye Bill

Just before passing the Longworth bill providing for the regulation of imports of coal-tar products, the House of Representatives, on Sept. 26, approved, by a vote of 207 to 62, an amendment by Representative Cannon of Illinois placing the licensing system created by the bill in the hands of the Federal Tariff Commission. The vote was non-partisan, the plan of having the Tariff Commission handle the licensing being opposed and supported by members of each party. The motion to recommit the bill and bring out a substitute prepared by Representative Kitchin, the ranking Democratic member of the Ways and Means Committee, was voted down 159 to 115. Mr. Kitchin's substitute carried lower rates of duties, but also provided for a licensing system and that it be administered by the Tariff Commission.

While the Democrats objected to the schedule of rates proposed in the Longworth bill, the main opposition to the measure came from within the Republican ranks and was directed against the licensing feature of the measure. This opposition was led by Representative Moore of Pennsylvania. No record vote was had on the licensing proposal, but amendments to that effect were voted down. A rising vote in the committee of the whole showed 86 for the licensing system and 53 against it; a later vote by tellers showed 94 for and 54 against the licensing plan, which defeated the proposal of Representative Moore to strike out the section which authorizes licensing. This made it impossible then to secure a record vote when the bill was considered in the House proper.

Representative Mondell, the Republican floor leader, in replying to the criticisms of the license system, said in part: "The Republican party will always adhere to the protective tariff system. It is carrying it out in this bill, but in connection with the industry proposed to be protected in this bill, a condition was found requiring temporarily the use of a policy of licenses in order to accomplish the very thing that a protective tariff does. It has been said that it would be possible to make the tariff rates high enough to obviate the necessity of a licensing system. That is true, but no one would be justified in voting for a tariff rate high enough to protect these industries in the immediate future. Rates could be made so high as to be burdensome to the enterprises using dyes. We do not want to burden those who must use dyestuffs, but we are desirous to build up a dyestuff industry, therefore the temporary expedient of adding to our tariff this provision for licensing. I think a manufacturer who depends for his business on the protective system should be willing to go to a little trouble to comply with the provision of a licensing system temporarily, if that licensing system is essential to the development of the protective policy."

The matter of turning the administration of the licensing system over to the Tariff Commission brought forth many acrimonious exchanges during the consideration of the bill. It was brought out that Chairman Page of the Tariff Commission believes that the Commission is wholly unfit to administer the law. He holds that the work of the Commission is of a research nature and that it was not planned to take over the administration of the licensing of dyestuffs. In fact, he believes that it will destroy the Tariff Commission. On the other hand, William S. Culbertson, regarded by many as being the

brains of the Tariff Commission, is strongly in favor of having the administration of the dye licenses placed in the hands of the Tariff Commission.

Meeting of the Society of Chemical Industry

The meeting of the American Section of the Society of Chemical Industry, held at Rumford Hall, New York, Nov. 21, was unique in the excellence of facilities for demonstrating the papers of the evening. Mr. Henry B. Faber in his paper on Industrial Filtration showed how valuable preliminary data could be obtained by the use of a one-sixth of a square foot paddle leaf. With a small electric suction pump, a graduated Woulff bottle and the single filter leaf, he was able to find the rate of filtration and the required wash water per unit area. Mr. Faber gave three classes into which most filtering problems can be divided: Slow filtering slurries, rapid filtering solutions and very rapid filtering granular products. For the first, the regular filter press is applicable. The open tank filter designed by George Moore, as well as the self-dumping type of filter, offers advantages when trouble is not likely to occur with the cloths or filtering diaphragms. The rotary filters find universal application in the second class and the centrifugal in the third. In washing the cake, Mr. Faber strongly recommended agitation with the wash water and refiltering, because the wash water can seldom be homogeneously driven through the cake.

Dr. Allen Rogers gave an illuminating account of the recent activities of the Ocean Leather Co. Two reels were given illustrating the methods used in catching sharks, turtles, etc. It is planned to publish a complete description of the processes, products and applications of fish leather in an early issue, so an abstract will not be given here.

Mining & Metallurgical Society of America Honors Charles Eugene Schneider

Charles Eugene Schneider was presented the Gold Medal of the Mining and Metallurgical Society of America at the conclusion of a testimonial dinner in his honor in New York, Nov. 24, 1919. Joining in the occasion by the attendance in a body of their presidents, boards of directors and secretaries, together with a large number of their members, were the national societies of Civil Engineers, Mining and Metallurgical Engineers, Mechanical Engineers and Electrical Engineers.

The distinguished French ironmaster declaimed any greatness except that thrust upon him, and paid glowing tribute to the thousands of associates and employees whose cheerful co-operation made possible the rapid recovery of French munition works after the first tide of German invasion. This spirit of co-operation between men of democratic lands was, in his idea, the hope of future peace.

Bradley Stoughton spoke of the former medalists and the significance of the token; Dr. Henry M. Howe recounted the technical achievements of the guest of honor; Charles M. Schwab spoke in a reminiscent vein of the open-hearted aid rendered by the Creuzot Staff to those at Bethlehem in its adolescence, while Col. Manus McCloskey told graphically the use to which the allied artillerists put the "75's," "long Schneiders" and "short Schneiders" in the late argument with the Hun.

Wood Ashes and Production of Potash

Data on the Potash Content of North American Woods — Details of the Manufacture of Wood Ash Extract — Estimate of the Cost of Manufacture

By ERNEST BATEMAN

DURING the period of the war much has been written on the subject of potash, its needs and the various sources from which it has or might be obtained. A few articles have appeared on the subject of potash from wood ashes. There seems, however, to be no article which brings together the available analyses of wood ashes and a detailed description of the methods used in preparing potash from them and it is felt that such a contribution would be of distinct usefulness. It is, therefore, proposed to bring together in this paper as much of the data on wood ashes and the production of potash from them as it is possible to obtain.

The best determinations of the ash content of American species of wood are those given by Sargent. From the list published by Sargent, the least important species have been omitted. The rest appear in Table I.

There are but few published analysis of pure wood ashes from known species. The best and practically the only reliable figures on the analysis of American wood ashes by species are those given by White.¹ White analyzed a number of woods, being very careful to have them clean and dry and free from bark. The results, given in Table II, were obtained from only one sample of wood for each species. In the softwoods, figures are given for longleaf pine (*Pinus palustris*) and shortleaf pine (*Pinus mitis* or *Pinus echinata*). More than half the lumber-cut of the United States in softwoods is probably of these two species. In the hardwoods, several oaks are given and more than half of the lumber-cut in hardwoods is oak. It is believed, therefore, that a fair idea of the amount of potash obtainable from the waste in lumber operations and from firewood can be obtained by using these averages.

The lumber-cut of 1915 was approximately 25,400,000,000 ft. b.m. softwoods and 5,800,000,000 ft. b.m. hardwoods. If we estimate that 25 per cent of this material reached the burners, then the total waste calculated to cubic feet is 527,500,000 cu.ft. of softwoods, and 120,000,000 cu.ft. of hardwoods. The annual consumption of firewood is about 71,000,000,000 cu.ft., of which approximately half, or 35,500,000,000 cu.ft., was estimated as hardwoods. Calculated on this basis, the total amount of potash annually produced by the burning of wood is as is shown in Table III.

Unfortunately, however, a very large proportion of this is not recoverable. Much of the potash in waste wood is volatilized* during the burning, while another

large portion is carried up the chimney as fine dust. This is particularly true of softwood waste; practically all of the ashes resulting from softwood is lost. More than 80 per cent of the wood that goes into firewood is used on farms, the ashes resulting being used in all probability as fertilizer, so that they cannot be considered as taking the place in the potash industry of that which we formerly imported. Of the total amount of ashes produced from wood burned as fuel perhaps not more than 15 per cent could be collected.

Wood ashes as they appear on the market are obtained from stoves or boilers and are quite different from the

TABLE I VARIATION IN ASH CONTENT OF SELECTED SPECIES OF WOOD

Species Common Name and Botanical Name	No. of Analyses	Min- imum	Ash Content Maximum	Average Per Cent
Cucumber tree (<i>Magnolia acuminata</i>)	5	0.25	0.34	0.29
Yellow poplar; tulip tree (<i>Liriodendron tulipifera</i>)	11	0.16	0.32	0.23

*It does not seem probable that the amount of potash lost by volatilization and dust can be decreased very much with present-day practice, because to reduce the intensity of the heat and draft would mean a redesign of the boilers and waste burners now in use. It is believed this would be much too expensive to make any such process economical in view of the small amount of potassium available. The use of the Cottrell process for precipitating the dust would also require new design of waste burners. Furthermore, calculations show that if the temperature of the flue gases is 200 deg. C. then the maximum amount of potash obtainable, if it were all volatilized or carried off as dust, would be approximately 1 lb. for every 400,000 cu. ft. of gas treated.

pure ashes as a basis for the calculations above. Wood as it is burned in commercial practice is never free from dirt, such as sand, which, although there may be very little in proportion to the weight of the wood, may and often does exceed the weight of the ashes obtained from the wood. Bits of charcoal and even sawdust are normal impurities in ashes.

In making an estimate of the amount of commercial wood ashes suitable for the manufacture of potash or to be used as fertilizer, it is believed that the ashes obtained from softwoods may be left out of consideration altogether. An attempt was made to collect information

Maryland	53,000,000	600
Maine	50,000,000	500
		57,600

IV gives such an estimate based on the yearly production of hardwood by States and the available ashes in Michigan.

These ashes are commercial wood ashes and contain, besides the pure ash, sand, cinders, charcoal, and probably sawdust. Some idea of the probable potash content can be obtained from Tables V, VI and VII.

Table V shows the variation in potash content in various species of wood. Table VI shows the variation in potash content of wood ashes produced by different industries. Table VII is a summary of all the wood ashes analyzed by the experiment stations of Massachusetts, New York and Connecticut, for the periods named.

TABLE V. VARIATION IN POTASH CONTENT OF COMMERCIAL ASHES FROM VARIOUS SPECIES

Species	Where Burned	State	Production, Per Cent	Water Per Cent	Sand Per Cent	Potash, Per Cent	Sol. Potash, Per Cent	Total Potash, Per Cent	Phosphoric Acid, Per Cent

TABLE VII. ANALYSES OF WOOD ASHES

Where Analyzed	Date	No. Analyses	Potash Content, Per Cent	Maximum Per Cent	Minimum Per Cent	Average Per Cent
Massachusetts	1868-1896 (14)	555	13.58	1.12	5.42	5.40
New York	1882-1907 (15)	65	10.00	1.10	4.50	4.50
Connecticut	1906-1915 (12)	111	7.46	0.23	3.62	3.62

Attention is called to the fact that in Table VII the more recent figures show a smaller average potash content than the older ones, and in several places in literature mention is made of the fact that the ashes are becoming poorer and poorer in potash. This may be due to the inclusion of a few samples of leached wood ashes, to changes in species burned, and to changes in the method of burning. The figures obtained for Connecticut

from the mills of the country cutting over 30,000 ft. b.m. of hardwood. This resulted in only partial success. Most of the mills apparently had no idea of the amount of ashes produced in their operation. Only in the States of Michigan and Wisconsin were the returns at all reliable. In these two States the mills for the most part were already selling their ashes, which probably accounts for their knowledge of the amount produced. It is believed, therefore, that an estimate based on the lumber-cut of hardwoods in the various States and the amount of ashes collected in Michigan and Wisconsin would be a conservative estimate of the easily collectible ashes, and would, if anything, be too small rather than too great, since the figures would not include the small mills or the small amount of softwood ashes and house ashes which is being used at the present time. Table

cut are probably more nearly correct for present-day practice than the others, and at any rate are conservative.

If the Connecticut figures are used as a basis, the total estimated production of potash from easily collectible wood ashes and hardwood sawmills is 2,100 tons, distributed as indicated in Table VIII. To this should be added the ashes which may be collected from softwood and the ashes collected from householders.

TABLE VIII ESTIMATED POSSIBLE PRODUCTION OF POTASH FROM HARDWOOD ASHES BY STATES

State	Amount Tons	State	Amount Tons
West Virginia	245	North Carolina	85
Michigan	215	Louisiana	85
Arkansas	185	Indiana	80
Wisconsin	170	Missouri	70
Penn. acer	155	New York	70
Kentucky	140	Virginia	115
Pennsylvania	125	Texas	25
Vermont	30	Mississippi	110
Ohio	110	South Carolina	20
Maine	20	Maryland	20

THE MANUFACTURE OF CRUDE POTASH FROM WOOD ASHES

The production of potash from wood ashes is confined chiefly to the States of Wisconsin and Michigan. There is some production in Indiana, Maine and Ohio, but it is an extremely small proportion of the total.

FIG. 1 TYPICAL EXTERIOR VIEW OF MODERN POTASH PLANT

There are only four factories in these three States; in Michigan there are twenty-six and in Wisconsin twenty-five.

METHOD OF PRODUCTION

The general method of production of crude potash from wood ashes is the same as that followed generations ago. It consists simply in leaching the wood ashes with water and evaporating the weak lye thus obtained. Apparently very little advance has been made in the art, the whole operation being carried on chiefly by rule of thumb methods. A number of potash plants have been built during the last year or so, of which Fig. 1 is a typical exterior view. The apparatus generally used in Michigan and Wisconsin consists of a battery of from 18 to 24 leachers, or, as they are termed in the trade, litches, an evaporator, or pan, and from one to two pots or kettles for the fusion of the material.

The leachers are merely vats provided with false bottoms, over which is laid a layer of straw, this in turn usually cemented in place with a quicklime paste. This straw and lime paste are rarely removed oftener than once in six months, and act merely as a filter. The leachers themselves, in cross-section, may be either

round or rectangular. If round, they are usually about 5 ft. in diameter and 5 ft. high. If rectangular, they may be 5 ft. each way; occasionally they are made 4 x 6 ft. and 5 ft. high. Such a vat will hold between 1½ and 2 tons of dry ashes. The bottom of the leachers are tapped with holes approximately 1 in. in diameter, through which the weak lye trickles into a trough made of galvanized or black iron very similar to that commonly known as the eaves trough in house construction. Figs. 2 and 3 are illustrations of a typical leaching battery. The leachers are raised, so that the trough at the bottom is inclined toward the evaporating pan. This is usually done by setting the leaching apparatus on piles from 4 to 6 ft. high.

The evaporating pan is a rectangular wrought iron pan, approximately 4 ft. wide and 9 ft. long by from 1½ to 2 ft. deep. This is sometimes corrugated, but the usual type of present-day pan has a flat bottom. It is set in brick work and is heated by a direct flame below. Usually a separate fire box is built for the pan, but in some cases the weak lye is evaporated to concentrated lye by the waste heat of the fire from the kettles. This is particularly the case when more than one kettle is used in one plant.

The kettles are cast iron, hemispherical receptacles approximately 4 ft. in diameter, with a slight flange at the top. They are set in brick work, sometimes with a flange 2 or 3 in. above the bricks. In a number of places a boiler plate flange 2 ft. high and about 5 ft. at the top and 4 ft. at the bottom is fastened to the top of the kettle to prevent it from boiling over during the operation of "melting."

The only equipment, in addition to these three main pieces of apparatus, required in the operation of a potash plant are the necessary ladles for dipping the concentrated lye from the pan to the kettle, scales for weighing the potash, some sort of iron receptacle for cooling the molten mass, particularly if iron drums are not used in the shipment of the material, and a good

FIG. 2 AND 3. PLAN AND SECTION OF A WOODASH EXTRACTION PLANT

Baumé hydrometer. Some plants have a gasoline engine attached to a pump for water supply. Some, more conveniently located, have their water supply piped to each vat. Some wet down their leachers by the use of a pail. Figs. 2 and 3 are plan and section of a typical potash plant.

The ashes collected are shoveled into the leaching

vats. Particular care is exercised to have them thoroughly tamped in the course of filling. This is sometimes done with an ordinary tamper and frequently by tramping, the latter method being used particularly by old potash makers.

The method of leaching varies to some extent, but in general that used in the greatest number of potash plants in Wisconsin and Michigan is as follows: The leachers are wet three times a day with approximately 10 gal. of water at each wetting. At the end of the third or fourth day, depending somewhat on the dryness of the ashes, the lye makes its appearance at the bottom

FIG. 4. BOILING POINT-CONCENTRATION CURVE

of the leach. A sample of it is caught, usually every morning, and tested for its density (specific gravity) with a Baumé hydrometer. Leaching is continued in most cases until the lye indicates 2 Baumé. When this point is reached the vat is discontinued and a new charge put in. Table XII shows the time required for the leacher to start running and the approximate strength of lye with each day's leaching. The figures given are

TABLE IX. APPROXIMATE DECREASE IN STRENGTH (DEG BAUMÉ) OF LYE AS LEACHING PROCEEDS.

At the Start	3	4	5	6	7	8	9	10	11
8	5	3	2	1	1	1	1	1	1
10	10	8	5	3	2	1	1	1	1
12	12	10	8	5	3	2	1	1	1
14	14	12	10	7	5	3	2	1	1
16	16	14	11	7	5	3	2	1	1
18	18	16	13	9	6	3	2	1	1
20	20	18	15	11	7	5	3	2	1
22	22	20	17	13	9	6	3	2	1

averages, so that individual cases may vary somewhat from those given in the table. The average initial strength is approximately 16 Baumé with the method of operation just described, the maximum running from about 25 to as low as 7 in isolated cases.

Table X shows the strength of a solution of crude potash using different Baumé degree readings. No attempt is made in practice to separate the strong from the weak lyes. All of them are sent to the evaporating pan, where they are evaporated to approximately 20 deg. Baumé.

TABLE X. RELATION BETWEEN DEGREES BAUMÉ AND AMOUNT OF DISSOLVED POTASH

Deg. Baumé	Per Cent Potassium Carbonate in Solution	Deg. Baumé	Per Cent Potassium Carbonate in Solution
0	0.6	12	9.6
2	1.6	14	11.3
3	2.3	16	13.1
4	3.0	18	15.0
5	3.9	20	16.8
6	4.6	22	18.7
7	5.5	24	20.6
8	6.3	26	22.3
9	7.2	28	24.2
10	8.0	30	26.2
11	8.8	32	28.3

The lye as it goes to the evaporating pan is usually a clear, pale, straw-colored liquid, but on evaporation the liquor becomes darker and darker, until it is a deep chocolate brown when it reaches the melting kettle. Frequently during the operation sludge (or "salts") settles, and this for the most part is composed of impurities which are soluble in the weak lye but insoluble in the more concentrated material and potassium sulphate. From the evaporating pan the strong lye is ladled over to the melting kettles, where the evaporation is carried on further. The temperature of the boiling liquor gradually rises, probably according to the curve in Fig. 4. No line of demarcation can be noticed between the point where all of the moisture disappears and the point at which fusion takes place, except that as the temperature rises the lye froths more and more until finally a maximum is reached, after which the frothing gradually subsides, leaving molten potash. This is then ladled from the kettle into cooling pans or iron drums, and is ready for shipment as crude potash.

This crude potash, or "first sorts," may vary somewhat in composition, but is in general a mixture of caustic potash, potassium carbonate, potassium sulphate, potassium chloride and insoluble matter. The following is given by Edgar as an analysis of "first sorts."

	Per Cent
Potassium hydroxide.....	65.64
Potassium carbonate.....	16.58
Potassium sulphate.....	16.03
Potassium chloride.....	0.35
Moisture and insoluble.....	1.40

COST OF MANUFACTURE

The cost of apparatus and installation varies of course with the local cost of lumber, brick work, plumbing, labor, etc., also according to whether or not a new building must be erected to house the plant. The following is an estimate of cost in 1917 in Wisconsin:

Building.....	\$2000 to \$2500
24 leachers at \$20.....	480
1 evaporating pan.....	300
2 kettles at \$50.....	120
Masonry, fire boxes, etc., with chimney.....	500
Plumbing.....	100
	\$3400 to \$3900

Any estimate of the cost of manufacture of potash is dependent almost entirely on the cost of labor, fuel and ashes. In Wisconsin and Michigan the potash maker or boss of the plant receives in the neighborhood of \$4 per day; laborers, about \$2.50; a man with team, \$6.

The following estimate of cost manufacture is based on a 24-leach plant running at full capacity, with an average of 10 days total time per leach and obtaining

125 lb. of crude potash from each leach, making a total of 90,000 lb. per year:

Depreciation at 33 1/3 per cent	\$1100
Interest on investment at 6 per cent	120
Labor cost—Potash maker at \$4	1200
2 laborers at \$2.50	1500
1 man and team at \$6	1800
Fuel—180 tons at \$7	1260
Repairs on kettles	120
Water	70
Electric light	30
Barrels—130 at \$1	130
Total yearly expense	\$7530
Manufacturing cost per lb. of crude potash, 8 1/2c	

The same plant, however, if running at half capacity, would have the following costs:

Depreciation at 33 1/3 per cent	\$1300
Interest at 6 per cent	120
Labor cost—Potash maker at \$4	1200
1 laborer at \$2.50	750
1 man and team at \$6	1800
Fuel—90 tons coal at \$7	630
Repairs on kettles	60
Water	35
Electric light	30
Barrels—65 at \$1	65
Total yearly expense	\$6190
Manufacturing cost per lb. of crude potash, 13 7/8c	

The cost of manufacture per pound is also dependent very largely on the amount of potash in the wood ashes. Table IX shows that if the lye starts to run at 22 Baumé, it will take 11 days for the leaching to be finished, but if the lye starts to run at 18 and 8 Baumé, it will take 10 and 7 days, respectively, to finish. The yields of crude potash in these three cases are as follows:

No.	Degrees Baumé	Days to Finish	Yields Crude Potash, lb.
1	22	11	152
2	18	10	106
3	8	7	44

A plant obtaining ashes such as No. 3 will cost practically as much to run as that obtaining No. 1; and there will be more work attached to the operation, since No. 1 will have to be filled only 27 times a year as against 43 times for No. 3. The cost of manufacturing 1 lb. of potash in each of these cases would be as follows: No. 1, 7.6c; No. 2, 9.9c; No. 3, 16.7c.

No attempt has been made to determine before purchase how much crude potash can be obtained from ashes and it sometimes happens that ashes are used which are so lean in potash as to result in a loss. Some simple method of estimation is needed whereby both the consumer and producer can tell with reasonable accuracy the amount of potash which can be obtained from a ton of ashes. The following method is suggested as giving a fair idea of the amount of potash obtainable: Place a 1-lb. sample of wood ashes with 1 qt. of warm water in a 2 qt. Mason jar. Screw the cover on tightly and shake the jar vigorously every two minutes for one-half hour. Allow the ashes to settle and filter the liquid layer through fine cheesecloth or, better still, filter paper. Test a sample of this liquor with a Baumé hydrometer. Refer to tables and multiply the amount of potash thus obtained by 2. This gives the percentage of crude potash by weight.

CONCLUSIONS

The following conclusions can be drawn from the paper:

The ash content of hardwoods according to the tables given ranges from 0.05 to 3.02 per cent, with an average of 0.61 per cent. The ash content of the coniferæ seems to vary from 0.02 to 0.82 per cent, with an average of 0.30 per cent. There may, however, be very wide variations in the ash content of the same species. This is

instanced by black walnut, with a minimum ash content of 0.21 per cent, a maximum of 1.96 per cent, and an average of 0.79 per cent, or chestnut oak, whose minimum, maximum and average ash contents are respectively 0.33, 1.96 and 0.77 per cent.

The potash content of pure, well-burnt ashes may be very high, ranging from 10 up to 35 per cent. These figures are, however, of but little commercial value, since all commercial ashes contain impurities, such as sand, sawdust or charcoal, and these impurities may make up a very large per cent of the total ash.

The potash content of commercial wood ashes may vary over a comparatively wide range, depending somewhat on the wood used and the kind of furnace or stove in which produced. The average of 11 analyses made in Connecticut from 1906 to 1915 was 3.6 per cent K₂O.

The initial cost of a potash plant of 24 leachers is between \$3000 and \$4000, provided a building has to be erected for that purpose.

The cost of manufacture of potash, not including the cost of the wood ashes, will vary from about 7c. to 17c. a lb., depending upon the kind of ashes obtained and whether or not the plant is running at full capacity. From this it is evident that the manufacture of potash from wood ashes will not be a paying proposition when normal prices are resumed, except in those cases where the plant has already been paid for and is owned by the potash maker who makes no charge for his own labor, but accepts his profits as compensation for his work. Under these conditions the cost of manufacture of potash, exclusive of the cost of ashes, may be reduced to about 5c. a lb. and might be able to compete with imported potash on a small scale under normal conditions.

Wealth of Ardlethan (New South Wales) Tin Mines

The New South Wales Government geologist recently visited the Ardlethan tin field and inspected the principal mines, including the Carpathia, White Crystal, New Venture, and Big and Little Bygoo. He expressed himself as impressed with the potential wealth of the field. In his opinion the time is not far distant when the ore deposits in these mines will be extracted in bulk and sent to the batteries, as much of the country contains payable tin which is now lost or overlooked. The geologist stated in his report that the Ardlethan field may be regarded as a valuable national asset.

Some Factors Involved in Drying Operations

AT THE April meeting of the Chemical Engineering Group of the Society of Chemical Industry at London, Mr. Eustace A. Alliot gave an important contribution on drying, from which the following is an extract:

In considering a drying problem, a most important factor—in addition to the quantity to be dealt with and the total amount of moisture to be removed—is the nature of the final dryness required. In connection with this matter "bone dryness" is often referred to, but as this term may cover quite a wide range of moisture percentage, even in regard to the same material, it is not sufficiently explicit. In case of a material such as ammonium perchlorate it may mean 0.25 per cent of moisture, and in the case of organic manures it may be in the neighborhood of 10 or 12 per cent. Further, one user

FIG. 1.

may be satisfied with 3 or 4 per cent residual moisture, while another dealing with the same product will require say $\frac{1}{2}$ per cent. The importance of the influence of the final dryness, not only on the time factor but also on fuel economy, is perhaps not sufficiently realized.

The accompanying curves show the influence of both initial and final moisture on length of drying and other factors. They relate to an experiment carried out in a small jacketed pan, 4 ft. in diameter, of a type more particularly described later. This pan was provided with agitators, and worked under vacuum. The test was carried out by the author at the works of Manlove, Alliot & Co., Ltd., Nottingham, by whose special permission it is possible to give the following particulars. It may be said that while these figures refer to a particular drier, they also have an important bearing on results in other types. The curves in Fig. 1 show the amount of moisture in the material at every moment throughout the process, and also the amount evaporated. The particular material dealt with was prussian blue, and the figures all relate to a charge of 140 lb. of dry color. It will be noted that the moisture percentage falls fairly regularly to about 5 per cent, but that under 2½ per cent the time lengthens out very much. The rate of evaporation remains fairly steady to about 12½ per cent, when it falls off very rapidly.

FIG. 2.

The curves in Fig. 2 indicate the length of the operation, including charging, heating up, and discharging the material. This time varies very definitely with the moisture conditions. From 60 per cent to 0.1 per cent the time is 7½ hr., from 60 per cent to 2.5 per cent 4.6 hr., but from 60 per cent to 10 per cent only 3.7 hr. From 30 per cent to 2½ per cent, 2½ hr.; from 10 per cent to ½ per cent, nearly 2½ hr., and from 2½ per cent to 0.1 per cent, 3½ hr. It will thus be seen that the drying period may be distinctly longer, even with a much smaller amount of moisture to be removed, if the final moisture is decreased.

In Fig. 3, the four curves on the left show the average evaporation during the period the material is actually in the machine. From 60 per cent to 10 per cent it will be observed that the average rate is 58 lb. per hr. From 60 per cent to 0.1 per cent little more half, or 32 lb. per hr. From 2½ per cent to 0.1 per cent the rate is barely 1 lb. hourly. The discontinuous curve shows the instantaneous rate of evaporation. It will be seen from this that the momentary rate at which water comes away at any particular moisture content varies curiously. At 63 per cent the rate is about 90 lb. hourly; this falls rapidly with decreasing moisture to a little under 60 lb., where it remains constant for quite a wide range of moisture content. Below 12½ per cent it again falls rapidly to zero, though if this portion of the curve were drawn on a time basis it would be seen that from this point of view the fall is a slow one. In the case of certain other materials the three parts of the curve merge smoothly into one another.

Fig. 4 shows the average output reckoned in lb. per hr. throughout the whole operation, including allowances for charging and discharging. At 60 per cent initial

FIG. 3.

FIG. 4

moisture the outputs are 37 lb. per hr. for 10 per cent final moisture, and 20 lb. per hr. for 0.1 per cent. For 10 per cent to 2½ per cent the output is about 1 cwt.; these weights refer to the dry material absolutely free from moisture. For the lower moisture percentages better results would be shown if the charge were somewhat larger.

The steam consumption follows similar lines to the foregoing (see Fig. 5). It should be said that the test results were irregular, owing to condensed water draining in from the steam supply pipes. In getting out these figures, therefore, a suitable loss of heat has been assumed. This method of calculation is perhaps a little unfavorable in the case of very low moisture content, and the figures might also be expected to benefit at slightly heavier charges.

The curves for the final moistures of 10 per cent and 2½ per cent are almost identical from 63 per cent to 20 per cent initial moisture, and vary from 1.23 to 1.65 lb. of steam per lb. evaporated. The figures for the 10 per cent curve are of little interest below this point. The final moisture of 0.1 per cent has a steam consumption ranging between 1.4 lb. to 2.4 lb. for initial moistures between 60 per cent and 10 per cent. For 2½ per cent initial and 0.1 per cent final the figure is 13 lb.

Fig. 6 gives the amount of dried material per lb. of steam. This varies from roughly ½ lb. at 60 per cent initial with almost any final moisture, and 3.3 lb. for 2½ per cent initial to 0.1 per cent final moisture.

The chemical properties are mainly important as they influence the material of which the drier can be constructed. If iron or steel is out of the question, one is largely limited to stationary types, as, generally speak-

FIG. 5

ing, agitated driers of other materials are either very expensive or are subject to very great difficulties of construction or reduction in the efficiency of the drier.

Of materials other than iron and steel, copper is perhaps the most used for pans or rollers, but it wears rapidly if scraped closely. Wood is a very useful material where hot air is the drying agent, and is employed with advantage for rotating cylinders. Lead or enamel is possible where the agitation is of a light nature and the agitators do not press on the lined surface. Enamel of course is a distinct hindrance to the efficient conduction of heat.

The temperature-sensitiveness of the material to be dried affects design, output and economy in an important measure. Generally speaking, low temperature means low economies, especially in hot-air drying. Materials sensitive to heat may be dealt with in vacuum or by hot air, or, in suitable cases, by film-drying or sprays. In the latter instance the time of drying may be exceedingly short and the average temperature also low.

The specific heat has little influence except at low initial moisture content or high final temperatures. The conductivity and the diffusion factor have undoubtedly

FIG. 6

an appreciable influence, especially when the amount of surface moisture is small and the material is in masses. The exact importance of this influence, is, however, difficult to determine.

METHODS OF HEATING

Methods of heating include furnace or direct heat, steam, hot water, and warm air.

In furnace-heated plants the economy is strictly dependent on the method of application. Control is a very important factor, but economy is also dependent on a high average initial temperature, with a low ultimate temperature for the used products of combustion. Batch machines are not economical when heated by direct furnace. In the case of a single machine the gases cannot be cooled sufficiently before they pass away to the flue, while if several machines are placed in a row the result is cumbersome brickwork, and varying conditions from machine to machine. It should be remembered that, in comparison with steam, gases are poor transferers of heat, and their efficiency is dependent upon high temperature and intimate contact with the cool material. The most suitable plant for utilizing furnace heat is the rotary continuous drier, which has the advantage of both high output and good economy.

The evaporation per lb. of fuel varies enormously with the conditions. In an ordinary efficient plant,

FIG. 7. PROPERTIES OF AIR

Assumptions—Air initially saturated at 10 deg. C. discharged half saturated

with medium conditions regarding materials and no very special supervision, 5 lb. of evaporation per lb. of fuel would be obtained, while under the best circumstances 10 lb. or more may be attained. In regard to fuels, coke is superior to coal where the products of combustion come into direct contact with the materials, while gas gives ease in control and requires little supervision.

Direct steam if economically raised and used may almost vie with direct-fire heat as regards economy. If it is assumed that 1 lb. of coal at the boilers will produce 6 lb. of steam at the drier, from 3 to 5 lb. of evaporation may be expected per lb. of coal at ordinary figures, though these may be less or more in extreme cases. Steam is a most efficient agent for batch drying, although it is applied with advantage to some continuous driers with equal results.

Superheated steam is, generally speaking, a delusion as a source of heat for drying. As it is a gas, its capacity for transferring heat is poor, and the capacity of a plant is liable to be much diminished by its use, which is only justified for very special requirements. Dry steam is all to the good, as there is less water to drain away from the heating surface. Hot water has to be used sometimes in order to dry delicate materials at low temperatures, but in this case again a great reduction of capacity may be expected. Steam at less than atmospheric pressure would be preferable to hot water in some ways, but it is not quite so easily applied and controlled.

Hot air has the great advantage that it can be brought into very intimate contact with suitable agitated and divided material, and thus large outputs may be obtained even at low temperatures. In certain cases its use, especially at low temperatures and high saturations, imparts a quality and texture to the product otherwise unobtainable. The air may be heated by a furnace-fired heater, but saturated steam is generally employed for this purpose. Under certain circumstances, where temperatures of 500-600 deg. F. are requisite, a gas-fired heater may be employed with advantage.

The economy is decidedly less than with fire-heated machines, owing to the lower initial temperature and output, especially with materials containing any appreciable amount of water. One lb. of coal under the boilers may evaporate 1.2 to 2 lb. of water in the driers, the air being heated to 80 or 90 deg. C. Under the best conditions one might possibly get 3 lb.

A great consideration is the amount of heat carried away by the discharged air. At low temperatures it will be seen from the curve in Fig. 7 that the amount of air required to remove 100 lb. of water, if half saturated, is very great; and consequently the proportion of heat lost is great. The upper curve shows this loss reckoned in lb. of steam, at 60 lb. pressure, condensed in the heater, per lb. of water removed. If this temperature of discharge can be raised in any way, the amount of air may be reduced in greatly increasing proportion, and this loss much diminished.

Now, with losses, such as that in the heated material, equalling the expenditure of heat in evaporation, an initial temperature of 90 deg. is needed to give the heat required to evaporate the amount of water the air will carry at 35 deg. C.; while initial temperatures of 800 to 1000 deg. C. or more are needed if the discharge temperature is 70 deg. C. or over. To enable similar economies to be obtained with lower initial temperatures, the air may be brought out of the drier at a higher final temperature than would be economical under ordinary conditions, and a portion of warm moist air is taken back to the heater and through the drying chamber, re-utilizing the heat, and attaining the required degree of saturation, so that the whole of the evaporation is carried away in the discharged portion.

The value of this device increases when the normal discharge temperature is low, for, as will be seen from the curve, a small increase in temperature means a large corresponding decrease in the loss of heat. It is also much affected by the temperature and saturation of the atmosphere at any given time; by the degree of moisture in the product being treated, and the readiness with which this is given up.

The curves in Fig. 8 represent, for a given initial temperature of 90 deg. C., the final temperature attained with various degrees of recirculation, together with the volume of air which passes through the drier to evaporate 100 lb. of water.

These curves illustrate the general tendency, but it should be observed that these are necessarily drawn on certain fixed assumptions. In practice it is necessary to exercise much judgment as to saturation percentages, etc., obtainable in each case.

The uses of vacuum are to increase the capacity per square foot of heating surface; to allow the use of ex-

FIG. 8. RECIRCULATION

Relation of discharge temperature to percentage of air recirculated and cu. ft. of air sec. passed through drier to evaporate 100 lb. per hour.

Assumptions—Air discharged 50 per cent saturated; outside air saturated at 10 deg. C. Radiation losses plus heat given to material equal heat for evaporation.

haust or low-temperature steam, if available; to shorten the period of drying and exposure of material to heat, and to reduce the average temperature of the material during drying. It is of special value where the last traces of moisture are to be removed.

There is little or no direct economy of fuel when vacuum is used. There is a certain reduction of heat losses and power, due to lower temperatures and accelerated drying, but these at times will be largely counterbalanced by the power used for the pump. It is too readily assumed that the temperature in a vacuum drier is the boiling point of water under the vacuum used. It may approximate very closely to this, so long as the moisture is evaporating freely, but as the water loses its mechanical freedom the temperature will rise. When the moisture is entirely in the pores of the material, especially if this be of a close texture, or the material is in masses or balls, the temperature will rise approximately to that of the heating medium, as a rule, soon after the moisture has been reduced to 5 per cent.

The output per square foot of heating surface varies very much with conditions. For ordinary steam-heated, agitated driers, not under vacuum, the evaporation will be from 2 lb. to 3 lb. per sq.ft. for fairly moist materials, reduced to a point at which they are dry to touch and appearance; with only 3 per cent moisture reduced to under 0.5 per cent, and a badly conducting material, the evaporation might only be $\frac{1}{2}$ to $\frac{1}{4}$ lb. per sq.ft. per hour. With materials of a nature from which the water evaporates very freely, such figures may be exceeded under suitable conditions. On the other hand, even where a fairly thin layer of moist material is worked between two heated surfaces, an evaporation less than 1 lb. per sq.ft.-hr. may be obtained. If the material is in the form of a thin film, outputs of from 2 to 8 lb. without vacuum are recorded. With materials which were not specially favorable, in ordinary agitated vacuum driers, this latter would be an extremely high figure, though not unattainable on occasions. A more usual figure for most moist materials would be 4-6 lb.

MEANS OF AGITATION

The object of agitation is to bring fresh portions of material into contact with the heating surface, and to break it up and turn it over to permit the free escape of vapor, thus materially increasing output, especially in the case of very low moisture content. In some cases its use results in a very definite saving in fuel, as, for instance, in utilizing direct-fire heat to its best advantage. In other cases, the fuel consumption may be the same or greater, but there is a very definite saving in labor and increased output for space occupied. In considering any type of agitator it should be remembered that the properties of the material may be very different at various stages of the process. A not unusual sequence is a thin, almost liquid paste, passing through a heavy clayey stage to large masses, which break down into more or less fine granules, ending up in a dusty powder. Hence the best design of agitator is usually a compromise. Possibly the material may tend to roll into balls, and it is then largely a question of the relative conductivity, porosity and cohesion as to whether this will prevent further drying or whether the balls will dry satisfactorily with further agitation.

Materials which cling closely to hot surfaces demand

powerful knives or plows. Some materials will tend to grow into a hard layer under such plows, unless, as is often arranged in film driers, the knife edge can be adjusted close to the surface at every point. An occasional remedy in such cases, where the rubbing action of the plow appears to lay the material on to the hot surface rather than to remove it, is to keep the scrapers or combs clear of the bottom, and follow up with hard-pointed chisels. In some cases it will be found that either no layer is formed, or that, if there is a layer, it will be comparatively soft, and will be effectively picked up and flaked off by the chisels as rapidly as it is formed. Rakes with staggered blades, arranged to push first in one direction and then in another, are very useful for materials which lack cohesion and which are not worked very deep.

Rotating cylinders fitted with lifting vanes are very effective agitators, especially for non-cohesive materials, when the vanes can be shaped to give an even curtain of falling material right across the machine. Balls or scrapers may be very useful adjuncts where the product tends to mass or build up on the shelves. Balls are very effective if they can be lifted and dropped, and if they are made with a hole through them they will have less tendency to collect a hard layer of dried product on their surface. They prevent material cohering in masses or adhering to the shell of the drier.

The speeds of agitators and revolving drums should, as a rule, be fairly low; too high speed absorbs power, may tend to cause the material to ball, and adds little, if anything, to the rate of drying.

In order to spread material in layers, it may be allowed to fall on to a traveling band passing over a hot surface. The most usual method is, however, to spread it or squeeze it on to rotating cylinders. The special advantage of this method is the shortness of the exposure to heat.

It is to be regretted that limitations imposed by the business policies of many of these concerns prevent the setting forth of interesting technical details. It is hoped, however, that the reader will get some idea of the number and magnitude of the problems of chemical industry that are being solved in this region. Great as the development has been, it is only a beginning. Unequalled transportation facilities, a plentiful supply of fuel, space for development without limit and a wonderful agricultural region to feed industrial populations are economic forces that are all working in favor of this district.

Belgian Commercial Museum Wants Samples

The commercial attaché of the American Embassy at Paris has received a request from Emile Jottrand, director of the Institut Commercial des Industriels du Hainaut, a high school of commerce and industry at 18 Place Warocqué, Mons, Belgium, for samples of American raw materials and graphic exhibits of manufacturing processes for use in its commercial museum. This institute formerly had an extensive exhibition, but the collections were ruined during the war. The director will be grateful to any American business concerns which care to send direct to him small samples, illustrations or catalogues that would be of interest in a practical commercial museum.

Electrically Heated Soaking Pits in the Steel Industry*

BY THADDEUS F. BAILY

President, the Electric Furnace Co., Alliance, Ohio

THE introduction of electrically heated furnaces to the heating operations subsequent to melting and refining in the steel industry has experienced the slow development incident to the introduction of all radical innovations in any industry. Many of the types that will find wide application in the future, while entirely feasible, have, when offered, been met with the statement that if such an equipment was a good thing, why were they not in general use. Other types, that have been in regular service for a considerable number of years, whose construction and operation are much more elaborate and whose commercial advantages are no greater, are now generally accepted as the most rugged and reliable equipment for the purpose. This latter refers to electric furnaces for the annealing and heat treatment of steel.

COST PER TON OF MATERIAL TREATED IN ELECTRIC VS. FUEL-FIRED FURNACES

The higher "fuel" cost for electric furnaces over fuel-fired furnaces that might have been used for the same purpose has been amply justified in commercial practice by the labor saving effected, the precision of the treatment produced, and the elimination of the rejections of parts due to defective heat treatment; the precision of the laboratory is obtained in regular plant practice.

There has been a reluctance of manufacturers generally to consider that there is a difference in cost per ton of material put through a furnace and the cost per ton of material heat treated and coming within the specifications. There has been no greater factor in changing this attitude than the conditions brought about during the war, where in a great many plants there was a wide difference between the quantity of material inspected and the quantity of material accepted. Manufacturers now are generally conceding the justness of the higher requirements for steel, and this is one of the greatest arguments in favor of electric furnaces.

ADAPTABILITY OF ELECTRIC FURNACE

Conspicuous examples of the electric furnace for heat treating are those for Liberty Motor crank shafts, over half of which were so heat treated; cast steel anchor chain, all of which was heat treated in furnaces of this character; and draw-bar knuckles, substantially half of those which are used in America being thus heat treated.

They are also adapted to other operations in the steel industry, and embrace soaking pits for the soaking of hot stripped ingots, re-heating furnaces for hot blooms and billets, combination fuel and electric furnaces for the heating of cold blooms and billets, recuperative car type annealing furnaces for bars and sheets, and automatic heat treating equipments for drop forgings and castings and for the heat treatment of steel rails and similar material.

The electric soaking pit for hot ingots is perhaps the

most promising development of the electric furnace to the steel maker, as the shortcomings of the present pits—whether of the fired or non-fired type—are well known, and many troubles of the rolling mill can be traced to the present type of pit.

The principal recommendation of the present type of pits, either of the fired or non-fired type, is the low fuel consumption per ton of metal soaked. This cost in a well handled pit is almost a negligible item, amounting frequently to only a few cents a ton.

THE ELECTRIC SOAKING PIT

However, in the larger mills, when running at full capacity, features such as lack of uniformity in temperature of the heated ingot, excessive oxidation of the ingot, and the like, are often such as to quite outweigh the item of mere fuel cost; and while it is to be admitted that electric pits cannot compete with fuel-fired pits under ordinary circumstances, when heating cold ingots, the time is not far distant when substantially all modern mills rolling hot ingots will use electric pits for this part of steel mill operation.

It has been difficult to overcome the prejudices against this innovation in ingot soaking; but the advantages to be gained are so apparent, and the success of electric furnaces in other similar fields has been so marked, that it will not be long until electric soaking pits will be in commercial operation.

It is to be expected that the cost for heat with an electric pit may be in excess of similar costs for gas-fired pits or unheated pits; but when taking into consideration that the electric pit will eliminate the roll breakages due to cold ingots, delays in the mill due to ingots unevenly heated, oxidation (thus producing a cleaner bloom and an actual saving in metal due to this elimination of oxidation, amounting to perhaps one-half of 1 per cent), as well as the ability of the electric pit to save labor, it is certain that the higher cost will be more than offset by the advantages, and that per ton of metal rolled in a given period the actual cost by the use of an electric pit will be less than by other means.

Fig. 1 shows the general arrangement and character of such a pit. This pit is provided with eight holes, instead of the usual four, and in consequence only half as many ingots will be located in each cell.

The resistance elements themselves, composed, as in all furnaces of this class, of broken carbon thrown loosely into a carborundum fire-sand trough supported on brick pillars, are located along the outer wall of each side of the pit, and protected against the liability of serious accident from the ingot by being recessed some distance back from the ingot cell itself. The heat from this resistance element, it will be noted, is radiated to the circular wall of the pit, and thence to the cover, the partition wall of the pit, and to the ingots themselves. The cross-section of this resistor element is such that there is very little difference between its temperature and the ruling temperature of the pit; and in actual practice most of the heating is done by the walls of the pit itself, rather than by direct radiation from the resistor element—this being of the highest importance in obtaining uniformity of heating.

In cases where the ingots cannot be delivered to the pit with enough heat for them to reach a high enough temperature without the addition of more heat from the pit itself, a longer time will be required by the ingots to

*Extract of a paper read at the fifteenth general meeting of the American Iron and Steel Institute, New York, May 23, 1919.

bring them to temperature, and at the same time the capacity of the pit in tons per hour will be reduced.

Taking as a basis ingots whose average temperature would be 1800 deg. F., requiring 300 deg. additional for bringing them to temperature, the capacity of the pit would be reduced to 24 tons per hr., the electrical capacity of the pit increased to 1500 kw., and the current consumption increased to 60 kw.-hr. per ton.

With the ingots charged at an average temperature of 1500 deg. F., the capacity of the pit would be reduced to 16 tons per hour, and the current consumption increased to 90 kw.-hr., without increasing the electrical capacity beyond 1500 kw.

to be heated, however, unless electricity can be obtained at an exceptionally low rate, and fuel can only be had at a high cost, a combination gas and electric furnace, such as shown in Fig. 2, wherein the earlier stages of the heating up to say 1800 deg. F. are handled by fuel, and the final temperature handled electrically, is perhaps the only type that can compete with the continuous fuel-fired billet heating furnace.

The advantage of uniformity in temperature, elimination of scale, etc., and more accurate control, will justify in many cases the use of such a combination furnace.

FIG. 1
Pit type furnace for soaking ingots for heavy gun forgings and ship shafts

Thus we have for a total of heating costs, including the renewals and repairs, and with power taken at 4c. per kw.-hr.:

For Hot Ingots.....	22½c. per ton
For Ingots at 1800° F.....	35c. " "
For Ingots at 1500° F.....	50c. " "

the final temperature in each case being taken as 2100 deg. F.

These figures can be safely taken as guarantees, and it can be expected that they will be much bettered in actual practice and operation over long periods of time.

CONTINUOUS TYPE RE-HEATING FURNACES

It is believed that this type of furnace will find wide application in the heating of cold steel for forging and rolling in relatively small capacities, and in re-heating steel of high quality; but where very large tonnages of cold blooms or billets are to be heated, a combination fuel and electric furnace will be better adaptable for such work.

An application that it is believed will find favor in certain steel mill operations is the use of an electric furnace for re-heating billets for finishing mills, wherein the blooms or billets coming from one mill are too cold to put into the finishing mill and will require approximately 300 deg. additional heat.

COMBINATION FUEL AND ELECTRIC RE-HEATING FURNACES

Where large tonnages of cold blooms and billets are

ANNEALING FURNACES

Of the annealing furnaces in the steel industry, the recuperative car type will have perhaps the widest application.

Fig. 3 illustrates a recuperative type of annealing furnace.

A notable feature of these furnaces is that the annealing will be done without the usual covers required in fuel-fired furnaces ordinarily used for this work, which will constitute one of the greatest savings in annealing, as compared with present methods. The recuperative type furnace lends itself to the highest economy, as after the steel has reached the full temperature and is passing toward the discharge end of the

FIG. 2
All electric billet heating furnace

furnace, a large part of this heat is given up to the cold incoming material.

Taking large steel mill practice of current at one-half cent per kilowatt, the cost of annealing in this type of furnace would not exceed 60c. per ton, which will compare favorably with coal-fired annealing furnaces from a fuel standpoint, and in addition will completely eliminate the expense of covers, as well as a considerable amount of labor and will introduce a precision in annealing which it is not possible to obtain with present equipment.

of the most difficult to heat treat, and the requirements were most exacting. Opportunity for obtaining the exactness of this treatment was in this case readily available, as test pieces were taken from each end of every piece, and it is interesting to note in connection with this rigid inspection that for days at a time, when producing even several hundred cranks a day, there would not be a single rejection for any cause. This fact not only speaks well for the heat-treating equipment but for all the previous operations in connection with the steel.

FIG. 3

Continuous recuperative car type annealing furnace for annealing tin plate, cold rolled steel and similar material

HEAT-TREATING EQUIPMENT

OTHER TYPES OF FURNACES

It is, however, in heat-treating equipments—which consist of two furnaces, one for the hardening temperature and one for the drawing temperature, in connection with a quenching mechanism located between—that electric furnaces have been first recognized as standard equipment for exacting work in the steel industry, and the earlier of these furnaces, especially of the automatic type, have been in use now for several years.

Fig. 5 shows a heat-treating equipment with a modification as to handling mechanism for anchor chain heat treating.

Large heat-treating furnaces of the automatic type, whose certainty of operation and precision of treatment have been clearly observed over several years, justify the consideration of the heat treatment of large tonnage of heavy material, such as steel rails. The build-

FIG. 4

Continuous automatic two-furnace heat-treating equipment, hydraulically operated, for heat-treating drawbar knuckles and airplane cranks

One of the most notable of these is an installation made at Sharon, Pa., over four years ago, which the following year was augmented by a duplicate installation.

A similar equipment of the same capacity was installed last year for the heat treatment of crank shafts for the 12-cylinder Liberty airplane motors. This equipment is shown in Fig. 4.

The steel used in these crank shafts was perhaps one

ing of equipments for such purposes presents no serious difficulty.

It is readily apparent to anyone interested in this subject that the heat treatment of rails is highly desirable, as the increased physical properties readily obtainable by a proper heat treatment are such as to very remarkably increase their efficiency, not only adding to the life from the standpoint of wear, but adding ma-

FIG. 5

Continuous two-furnace heat-treating equipment for heat-treating cast steel anchor chain

terially to the ultimate strength and the elastic limit, without appreciably sacrificing the ductility or toughness; and the only real question that can be raised is whether successful heat-treating equipments can be found wherein every rail treated will have exactly the heat treatment specified, and whether such equipment can be rugged enough to operate with precision over long periods of time, and the cost of operation come within a reasonable commercial range.

CONCLUSIONS

Where requirements of the steel specified must be met, a lower cost may readily be found in operating electric furnaces, when taking into consideration the difference between the cost per ton of material put through the furnace, as compared with the cost per ton of material meeting the specifications.

Many of the arguments used against the introduction of electric furnaces were used against the introduction of large motors in the steel mills, and against electric haulage, and the statements frequently made through all the years about any innovation that "it has not been done and it cannot be done" must gradually yield, as one by one the various types of electric furnaces from heat treating equipments to soaking pits go into regular, commercial and economical service.

EDITOR'S NOTE—Professor J. W. Richards, in discussing Mr. Baily's paper, dwells on the possibility of introducing electric heating furnaces at points removed from cheap fuel and where hydro-electric power is cheap. He cites the case of the Girod Steel Works at Ugines, France, where they use entirely electric power. He also has to say to iron and steel men the following:

"Iron and steel men do not pay a fraction of the attention which they should to reduction of radiation losses from furnaces and very hot apparatus. They paint surfaces black, the best color to radiate heat, when they should be painted white. They smile the sarcastic smile of contented ignorance when it is suggested to them that heat losses can be largely diminished by proper attention to the radiating surface. Tell a foundryman that heat could be saved in sufficient quantity to pay well, if he had the outside of his furnaces nickel plated and kept them bright, and he would prob-

ably regard his informer as demented. Yet in many cases the statement would be true, and doubly true of electric furnaces.

"I strongly urge the use of white aluminum paint as one step in reducing radiation losses on furnaces. Some of our laboratory furnaces are encased in polished monel metal; it would undoubtedly be well to encase steel works electric furnaces in this manner. Even bright nickel plating of ordinary iron shells would in most cases pay for itself in heat saved in a short time.

"I plead with practical men not to ignore these 'laboratory' suggestions; they are practical, and they will save money. Mr. Baily's whole article is a demonstration of the possibility of extending the precision, accuracy and economy of laboratory methods into the steel mill. An extension of this work will mean almost the remaking of our steel industries. These are the directions for scientific progress in the steel industry."

The World's Cotton Production.—In the July, 1919, issue of *La Technique Moderne*, Prof. JAMES DANTZER presents some interesting statistics on the cotton industry of the world. From recent data, the total population of the world may be taken as 1640 millions, distributed as follows:

Asia—905 millions, or 20 inhabitants per sq.km.
Europe—420 millions, or 42 inhabitants per sq.km.
America—150 millions, or 4 inhabitants per sq.km.
Africa—150 millions, or 5 inhabitants per sq.km.
Oceania—7 millions, or 0.7 inhabitant per sq.km.

The total for 1810 was 680 millions, so the average yearly increase in population may be taken as 9 millions.

The world's cotton production for 1913 was 4886 million kg., or 2.97 kg. per capita. Of this raw cotton, 3920 million kg. was required for the production of 3500 million kg. of spun cotton (allowing 12 per cent waste), which gave, in turn, 3325 million kg. manufactured cotton goods, or 2.02 kg. per capita. The remaining 965 million kg. (0.58 kg. per capita) was used in the manufacture of absorbent cotton, guncotton, etc.

Hence, assuming the per capita requirements to average 2.97 kg., a yearly increase in population of 9,000,000 would necessitate the production of an additional 27,000,000 kg. of raw cotton.

La Technique Moderne, July, 1919. p. 352.

Determination of Sulphur and Chromium in Steel

BY LOUIS A. GOLDENBERG

A METHOD has been developed in this laboratory, whereby the same sample is used for determination of both sulphur and chromium. Sulphur is determined by the evolution method, chromium, with slight variation, by the silver nitrate-ammonium persulphate method, described by H. L. Hamner in METALLURGICAL & CHEMICAL ENGINEERING, Sept. 1, 1917, p. 206, sulphuric acid instead of hydrochloric acid being used to put the steel into solution.

A long series of tests were run, especially with reference to the sulphur determination, to make absolutely sure that the sulphuric acid would in no way influence the sulphur results. It was proved beyond doubt that the use of sulphuric acid gave results identical to those obtained when using hydrochloric acid. We have accordingly been using this method for several months.

A 3-g. sample is weighed into a 500-cc. Erlenmeyer flask, and the flask marked with the symbol Cr, when chromium is to be determined. It is attached to the evolution apparatus, which consists of a stand about a foot high, under which is an Argand burner. The Erlenmeyer is supported on this stand, and is closed with a two-holed stopper. Through one hole there is a safety thistle tube, the lower end of which reaches below the acid in the flask, while through the other there is a long tube reaching into a tumbler, which sets on the desk. Ten cc. cadmium chloride solution (1) and 150 cc. water are put into the tumbler, and 100 cc. sulphuric acid solution (2) poured through the thistle tube, and the burner lighted. When evolution is complete, the flask is disconnected, the thistle tube washed down, and the flask set aside for the determination of chromium. The presence or absence of chromium is shown positively by the color of the solution, chromium giving the solution a decided deep green that cannot be mistaken, so that should any alloy steel come into the laboratory marked as a plain carbon steel, the mistake is detected at once, and the sample run for chromium, without having the routine interrupted in any way.

To the tumbler is added 2 cc. starch solution (3) and 25 cc. hydrochloric acid solution (4) are run in, and it is titrated immediately with a standard potassium iodide-potassium iodate solution (5) to a deep blue end point.

To the solution remaining in the flask is added 10 cc. nitric acid-silver nitrate solution (6), the flask is placed on the hot plate, and boiled gently, until nitrous fumes are completely expelled. It is diluted to 300 cc., heated to boiling, 10 cc. ammonium persulphate (7) carefully added, and boiled until manganese dioxide is completely precipitated. Now 2 cc. hydrochloric acid (1:1) is added slowly to prevent sudden boiling over, to destroy the manganese dioxide, and the flask is gently boiled for 15 min., until the silver chloride which has been formed is entirely coagulated.

The flask is then cooled in running water, 2 cc. potassium ferricyanide (1 per cent) added and titrated to a deep blue end point, with standard ferrous ammonium sulphate solution (8), which has been standardized against a standard government steel.

1. Cadmium Chloride Solution.—Dissolve 180 g. CdCl_2 in 7200 cc. H_2O , then add 10,800 cc. NH_4OH .

2. Sulphuric Acid Solution.—To 14,750 cc. water add 3250 cc. H_2SO_4 .

3. Starch Solution.—Mix 10 g. starch in about 15 cc. cold water, add about $\frac{1}{4}$ in. stick NaOH , and stir until mass gelatinizes. Add cold water until mass is liquid and put it into 500 cc. boiling water, and boil 2 to 3 minutes.

4. Hydrochloric Acid Solution.—To 3600 cc. water add 14,400 cc. HCl .

5. Standard Potassium Iodide-Potassium Iodate Solution.—Dissolve 12.0528 g. KIO_3 and 130 g. KI , and dilute to exactly 18 liters. Standardize against a standard steel of known sulphur content, following the same directions as given above, and using for a factor the results obtained by dividing the known sulphur content by the number of cc. of standard solution required.

6. Nitric Acid-Silver Nitrate Solution.—Dissolve 540 g. AgNO_3 in H_2O , dilute to 11,000 cc., add 7000 cc. HNO_3 .

7. Ammonium Persulphate Solution.—Dissolve 5400 g. $(\text{NH}_4)_2\text{S}_2\text{O}_8$ in water, and dilute to 18 liters.

8. Ferrous Ammonium Sulphate.—Dissolve 432 g. $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2$ in H_2O , dilute, add 180 cc. H_2SO_4 , and dilute to 18 liters. Standardize against a standard steel of known chrome content, running in the same way as above, and using for factor the results obtained by dividing known chrome content by number of cc. standard required. Or standardize against KMnO_4 , by running about 40 cc. $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2$ out of a burette into 100 cc. H_2O , adding 5 cc. H_2SO_4 , and titrating with KMnO_4 . One cc. $\text{N}/10 \text{ KMnO}_4$ equals 0.00173 g. Cr.

The principal advantage is the saving in time, of weighing up the sample, and putting it in solution in sulphuric acid. It is also of great advantage in time saving to have the sample ready to run for chromium, if due to error in marking sample, no chromium has been weighed up. In this connection, the color of the acid solution in the flask is an absolutely sure indication of the presence or absence of chromium.

In comparing the silver nitrate-ammonium persulphate method with the older one, of oxidizing with potassium permanganate and filtering off the manganese dioxide, the saving in time here also is very great. This, however, is taken up by the originator of the method, Mr. Hamner, in his original article.

However, two advantages of our method over those of Mr. Hamner might be mentioned. In dissolving a large number of samples in open beakers, the contents of some of the beakers invariably evaporate faster than others, so that unless constantly watched, spattering results. This is entirely done away with where the solution takes place as described, because the original volume of acid is not changed by evaporation.

Furthermore, in titrating, using one solution instead of two is an advantage, although of course the sample cannot later be titrated for vanadium. Also, the deep blue ferricyanide end point is much sharper, and leaves less to the operator's individual judgment than the permanganate end point.

One last item might be mentioned in connection with the sulphur determination. When hydrochloric acid is used as a solvent—hydrochloric acid often volatilizes, and is driven over into the cadmium chloride, where it tends to neutralize some of the ammonia, and rise from the tumbler as ammonium chloride. This is especially likely to happen, if, in an attempt to hurry the operation, the flame under the flask be raised too high. When using sulphuric acid, however, this does not occur.

Lime-Barium Softener for Treatment of Boiler Feed Water

Description of a Successful Water-Softening Installation for the Production of Sulphate-Free Boiler Water—Operating Procedure: Charging and Washing Filters, Sampling and Analyzing, Gaging Flow With Weir—Water Reports

By C. A. MEHRING

THE method of softening water for boiling purposes by the lime-barium treatment has been carried on with considerable success for the past two years at the Chino Copper Co.'s plant at Hurley, N. M. The softeners used are manufactured by the Reisert Automatic Water Purifying Co. of New York. The apparatus consists of a raw water tank, a settling tank with gravel and filter embodied, a lime slacking tank, a saturator and sludge tank.

The raw water is admitted to the plant through a float valve at the end of the raw water pipe *E-1*. Through this valve the water is discharged into the small compartment of the raw water tank. The float valve is controlled by a float in the settling tank, or a filter compartment, which is raised or lowered in proportion to the amount of soft water drawn off. From the small compartment the water passes through a rectangular weir into the large siphon compartment. Through this siphon the water is discharged into a siphon discharge tank riveted to the bottom of the raw water tank. The air which accumulates here escapes through vent *Y*. From the discharge tank the water flows intermittently through pipe *D*, *D-1* to the bottom of the outer, or lime, cone.

THE LIME SATURATOR

The lime saturator is a cone-shaped tank, consequently all suspended matter and precipitate settle to the bottom and can be drawn off through cock *R* to sewer. The suspended matter and precipitate are due to the make-up of the raw water and insoluble calcium carbonate in the lime. The required amount of lime for the saturator is slacked in the slacking tank by the addition of just enough water to make the consistency of cream. This lime is added to the saturator through cock *H-1* and pipe *H* into the bottom of the saturator. The raw water from the raw water tank is admitted to the saturator through a rectangular weir *J-1* and pipe *J*. This water entering the bottom of the saturator comes in contact with the cream of lime and on its way to the lower cone through pipe *K*, *K-1* and *K-2* becomes saturated with lime. This lime water meets the raw water at the bottom of the lower cone, removing the temporary hardness. The precipitates settle out and sink to the bottom of the cone. From here they are drawn off through cock and pipe *N* to sewer. The water then rises from the lower cone and enters the inner, or barium, cone, through pipe *C*, which has the same diameter as the siphon pipe. The speed of the water flow is very high, consequently the barium carbonate is thoroughly stirred up so that it comes into intimate contact with the water, removing the sulphates. The reactions take place in the water on its way to the top of the inner tank. Here the area is greatly increased, hence the speed of the water is materially decreased, allowing the precipitate of barium

sulphate to settle and sink to the bottom of the inner cone. Therefore most of the precipitate is removed before the water reaches the holes near the top of the main tank. Through these holes the water flows into the outer annular space which contains the filter.

THE FILTER

The filter consists of a perforated plate, a brass screen, 6 in. of gravel and 16 in. of sand. The softened and filtered water is collected in a triangular space below the filter bottom. From here it is drawn off through pipe *B* and *B-1*, in which pipe line a shut-off valve is provided to prevent the raw water from entering softened water storage tank while the filters are being washed. This pipe is raised sufficiently above the sand so that should the raw water be shut off entirely, the water will not be lowered below the sand on the filter. In the space below the filter bottom is an annular perforated pipe *G* for the air wash. For an even distribution the air is admitted at four points. This is also the case with the wash water pipe *E*, which connects with the raw water pipe *E-1*. Above the sand four semi-circular baffles are provided at the end of pipe *A*. These baffles prevent any sand from being washed over through pipe *A-1*, *A-2* to sewer while filters are being washed.

METHOD OF CHARGING SOFTENERS AND WASHING FILTERS

The valve 5 at the end of the raw water pipe *E* is closed, preventing any water from entering the softener. Cock *R* is opened, sludging out the lime saturator. This cock is left open until the heavy precipitate is all washed out, or until the water becomes almost clear. Cock *N* is opened, allowing the sludge from the lower, or lime, cone, to flow to the sewer. This cock is left open until the water is almost clear. Cock *M* is opened, allowing the precipitate of barium sulphate and unused barium carbonate to flow into the sludge tank. From this tank it is forced back into the lower, or lime, cone, by means of a steam injector. Valve 1 is closed, shutting off the water through pipe *B*, thus preventing its entering the soft water storage tank. Valve 4 is opened cautiously, as this is the high pressure air which escapes through the perforated annular pipe under the sand and gravel of the filter. Care must be taken not to agitate too violently, lest sand and gravel become mixed. The action of the air loosens the precipitate which has adhered to the sand and gravel of the filter. Valves 2 and 3 are then opened. Valve 3 allows the raw water to rise through the filter-bed, washing all precipitate, loosened by the action of the air through valve 2 and filter sludge pipe, to sewer. When filter is sufficiently washed, valves 4, 3 and 2 are closed, and valve 1 opened, allowing softened water to flow to storage tank when softener is again in operation. The required amount of barium carbonate is then charged to the barium cone through the barium funnel. The lime in the lime slacking tank,

which has been slacked to creamy consistency, is charged to the bottom of the lime saturator through cock *H-1*, and pipe *H*. Valve 5 is opened, allowing the water to flow to the siphon tank. The float on this valve automatically controls the operation of the softener for the remainder of the shift. The operation of charging, sludging and washing filters is performed every 12 hours.

METHOD OF COLLECTING SAMPLES

All water samples are drip samples taken by means of $\frac{3}{8}$ in. pipes connected at various places on the softeners: The raw water connected on pipe *E-1*; the saturated lime water on pipe *K-2* in the lower, or lime, cone; the softened or treated water on the triangular space below the filter bottom. These drip samples cover a period of 12 hr., at the end of which time they are analyzed. At the end of sludge pipe *N* a sample is taken at time of sludging and analyzed for barium carbonate. This is done as a precaution against an undercharge or overcharge.

METHOD OF ANALYSIS

The method of analysis indicates the following in equivalent amounts of calcium carbonate:

1. Alkalinity to methyl orange (M.O. Alk.)
2. " to phenolphthalein (Pt. Alk.)
3. Free carbon dioxide.
4. Negative hardness (Na_2CO_3)
5. Temporary hardness.
6. Permanent "
7. Magnesia.

SOLUTIONS REQUIRED

Standard N/25 H_2SO_4 ,

1 cc., equivalent to 0.002 grain CaCO_3 .

Standard N/10 Na_2CO_3 ,

1 cc. is equivalent to 0.005 grain CaCO_3 .

Standard N/10 (Na_2CO_3 and NaOH equal parts), called soda reagent.

1 cc. is equivalent to 0.0005 grain CaCO_3 .

Distilled water neutral to methyl orange.

Methyl orange indicator (M.O.)

Phenolphthalein indicator (Pt.)

1. Alkalinity to Methyl Orange.—Titrate 100 cc. of water with N/25 H_2SO_4 , using methyl orange indicator. Cc. of acid used times 1.17 equals the alkalinity to methyl orange in grains per gallon.

2. Alkalinity to Phenolphthalein.—Titrate 100 cc. of water with N/25 H_2SO_4 , using phenolphthalein indicator. Cc. of acid used times 1.17 equals the alkalinity to phenolphthalein in grains per gallon.

3. Free Carbon Dioxide.—Titrate 100 cc. of water with N/25 Na_2CO_3 , using phenolphthalein indicator. The first faint tinge of pink is the end point. Cc. of Na_2CO_3 used times 1.17 equals the free CO_2 in grains per gallon.

4-5. Permanent or Negative Hardness.—Boil 100 cc. of water 10 min., add 5 cc. N/10 "soda reagent." Boil further to $\frac{1}{2}$ volume. Filter, wash and titrate all of the filtrate with N/25 H_2SO_4 , using methyl orange indicator [(5 cc. "soda reagent" times 2)]—cc. acid used times 1.17 equals permanent hardness if plus, or negative hardness if minus, in grains per gallon.

6. Temporary Hardness.—Temporary hardness is equal to the methyl orange alkalinity minus the negative hardness.

7. Sulphates of Iron, Aluminum, Magnesium, etc., Classed as Magnesia.—Boil solution from determination No. 1 in a covered beaker 15 min., add 25 cc. saturated lime water and allow to stand near boiling temperature 15 min. Filter, wash and titrate all of filtrate with N/25 H_2SO_4 , using methyl orange indicator. Cc. acid used = *X*. Run blank in same manner, using distilled water with cc. acid = *Y*. Then (*Y* — *X*) 1.17 = magnesia, etc., in grains per gallon.

CHEMISTRY OF PROCESS

Reactions of impurities and lime.

Reactions of impurities and BaCO_3

Reactions of impurities and Na_2CO_3

Reactions of impurities and NaOH

MgCO_3 is a product of reaction (20)

TABULATED DATA REDUCED FROM EQUATIONS 1-29

One Part Impurity	Equivalent Parts CaCO ₃				Impurity Indicates Equivalent Parts CaCO ₃
	Requires for Treatment			Parts CaO	
	BaCO ₃	Na ₂ CO ₃			
Free CO ₂	1				1
NaHCO ₃	2				2
CaH ₂ (CO ₃) ₂	1				1
MgH ₂ (CO ₃) ₂	2				2
FeH ₂ (CO ₃) ₂	1				1
CaSO ₄	1				1
MgSO ₄	1	and	or	1	1
FeSO ₄	1	and	or	1	2
Fe ₂ (SO ₄) ₃	3	and	or	3	6
Al ₂ (SO ₄) ₃	3	and	or	3	6
CuSO ₄	1	and	or	1	2
H ₂ SO ₄	1	and	or	1	2

Each equivalent part of CaCO_3 requiring CaO for treatment requires 0.56 parts CaO .

Each equivalent part of CaCO_3 requiring BaCO_3 for treatment requires 1.97 parts BaCO_3 .

The impurities in water causing hardness are:

Non-scaling	Free CO_2 (corros.) NaHCO_3 $\text{CaH}_2(\text{CO}_3)_2$ $\text{MgH}_2(\text{CO}_3)_2$ $\text{FeH}_2(\text{CO}_3)_2$	Negative hardness
Scaling	Non-corrosive CaSO_4 MgSO_4 FeSO_4 $\text{Fe}_2(\text{SO}_4)_3$ $\text{Al}_2(\text{SO}_4)_3$ CuSO_4 Corrosive H_2SO_4 (non-scaling)	Permanent hardness

14,000-GAL. LIME-BARIUM WATER SOFTENER PLANT

FeSO_4 , $\text{Fe}_2(\text{SO}_4)_3$, $\text{Al}_2(\text{SO}_4)_3$, CuSO_4 , H_2SO_4 , etc., are occasionally found in boiler waters. These impurities are precipitated by BaCO_3 .

METHOD OF SETTING WEIR TO LIME SATURATOR

On the raw water compartment of the siphon tank are two rectangular weirs *J-1* and *J-2*. *J-2*, the larger weir, is 3.5 in. wide. *J-1*, the small weir, is 1.25 in. wide. The two weirs are at the same height from the bottom of the raw water box, hence a proportionate amount of water may be discharged through each.

Method of setting weir *J-1* to lime saturator so that the required amount of saturated lime water may be discharged from the saturator to the lower, or lime, cone of softener.

The raw water must be analyzed at the beginning of each shift to find the required amount of lime to be added to the saturator. For example:

Temporary hardness	= 12.9
Twice negative hardness	= 3.2
Magnesium	= 6.1
Free CO_2	= 0.0
Total	= 22.2 = Grains per gal. CaCO_3 .
$\text{CaCO}_3 : 22.2 : \text{CaO} : x$	
x = acid carbonates.	
Saturation of lime water : acid carbonates : 3.5 in. (width of weir <i>J-2</i>) : x .	
x = width of opening in weir <i>J-1</i> .	
Barium Carbonate Required.— CaCO_3 equivalent of the permanent hardness of the raw water in grains per gallon $\times \frac{1.97}{7}$ = lb. of C.P. BaCO_3 required to treat 1,000 gal. of water.

COST OF TREATMENT

Month of February, 1919

83 bbl. lime at \$2.18 per bbl.	\$180.94
1,040 lb. BaCO_3 at \$3.27 per cwt.	34.01
Labor operation	164.00
Miscellaneous supplies	5.84
Steam for injector	5.35
Total cost of treating 6,697,000 gal. water	\$390.14
Cost of treating 1,000 gal. water	.058

MISCELLANEOUS DATA—AVERAGE FOR THE MONTH

Lb. of incrustants in raw water	11,920
Lb. incrustants removed	10,045
Lb. incrustants in treated water	1,875
Lb. incrustants in 1,000 gal. raw water	1.74
Lb. incrustants in 1,000 gal. treated water	.29
Cost to remove 1 lb. incrustant	\$0.0386

Considerable experimental work has been done on different waters, from spring water to tailings water from a copper precipitating plant, showing that most any

CONTROL WEIRS ON RAW WATER TANK

water can be treated satisfactorily in this type of softener.

Before the installation of this softener, trouble was experienced due to priming and foaming of the boilers and to a large amount of very hard scale which was difficult to remove, but since the operation of this plant these troubles have been eliminated.

New Metal Alloy

During the war an Italian engineer, Adolfo Pouchain, after a series of experiments succeeded in producing a new alloy of zinc and copper, which has been given the name "biakmetal." This alloy quickly demonstrated its usefulness in Italian industry, and by reason of its special qualities promises to attain similar success throughout the world. Biakmetal has aroused considerable interest in Italy. A certain large manufacturer has said that his metallurgists have made every effort to determine its exact composition, but without success.

From a small beginning the demand for biakmetal has increased to such an extent that a new company, the Stabilimenti Biak, S. A., of Turin, having a capital of 12,000,000 lire (\$2,316,000), has been formed to carry on its manufacture. The industrial value of a product which is stronger than steel and less corrosive than copper is evident, and it is claimed that biakmetal, which has passed the experimental stage, possesses these qualities. The most important characteristics are stated to be as follows: (1) The highest known breaking point; (2) the highest limit of elasticity; (3) perfect homogeneity; (4) high resistance to thermic action; and (5) high resistance to chemical action.

Biakmetal is extremely well adapted for almost any kind of manipulation. It can be successfully cast, turned, drawn, forged, rolled and stamped. While its development is still in progress, it has already proved especially useful in aeronautic and marine construction on account of its light weight, its unusual strength and its anti-corrosive qualities. In its different forms it may be substituted for steel, brass and aluminum, and for certain uses has important advantages.

Operation of a Gas Producer

By J. S. McCLIMON*

MOST articles on gas producer operation consist of a long discussion of theoretical conditions or chemical reactions. It is the aim of this article to reduce the causes and effects of these things to a rule-of-thumb method which will be of assistance to the operator or superintendent and may be applied to everyday operating conditions met with in producer practice.

STARTING THE PRODUCER

A new producer, before being started, should be dried out several days with small fires. This is a precaution which, if properly carried out, will add considerably to the life of the lining. After the producer has been thoroughly dried, all large pieces of wood likely to cause trouble should be removed and the producer filled with ashes to a depth of at least 12 in. over the top of the blower. It is best that a few large clinkers be placed around the openings of the blower to keep them from becoming clogged with fine ashes. These ashes are necessary to protect the metal parts of the producer. They also act as a diffusing medium to distribute the blast over the entire fuel bed, thus insuring even combustion.

To start the producer, it is necessary only to level off ashes, throw in several armfuls of small dry wood, saturate with kerosene, and light with a piece of waste. After the wood has burned for a few moments, turn on about 10-lb. blast and blow until the wood is well ignited. A small amount of coal can then be dumped and the fires be built up gradually. Care should be taken that the coal is not fed too fast. Allow a good bed of coke to be formed before any attempt is made toward crowding the operation of the producer. One should remember that it takes several hours to get a producer fire built up properly to the point where it is making good gas.

No special attempt need be made at this point to get the fire distributed over the entire fuel bed. It will spread of itself later, and it is usually better to have a good fire at one point than several small ones scattered over a larger area.

In case it is necessary to stop the producer at any time, the blast should be turned off immediately and never exceed 10 lb. during this idle period.

THREE ZONES

The various zones of the producer are shown in Fig. 1. It can be seen that there are three—the ash, the incandescent or the fire zone, and the green coal zone, the last consisting of coal which has not received a sufficient amount of air to become incandescent. This is also termed the distillation zone. The existence of these three zones is a point often overlooked in the operation of the producer.

MEASURING FIRES

The usual method of measuring the fires is for the foreman to take a rod about 5 ft. long, which he inserts in one of the poke-holes in the producer top until he establishes the height of the fuel bed. This method is totally inadequate, because no attention is given to the depth of the fire zone, the most important point of all

in the operation of a gas producer. If the ash zone is allowed to exceed a reasonable limit, say 15 in., the fire zone is considerably reduced, and it is impossible to carry the proper depth of fire if the ashes are not kept within a reasonable limit. This tendency of the ashes to crowd out the fire zone makes it possible for the top of the fuel to be at the proper height and yet the fire may be so thin that the gas will be of exceedingly poor quality.

The only way the fires can be measured properly is to force the rod completely through the fire and allow it to remain long enough to become red hot. After the rod has been withdrawn, it is easy to see the part which has been in contact with the hottest portion of the fire and the part which has been protected by the ashes. Knowing the distance to the blower or the metal parts of the producer, it is a simple matter to tell exactly the depth of the various zones.

A very convenient rod for this work is shown in

FIG. 1
IDEAL CROSS SECTION OF PRODUCER

the view and consists of a $\frac{1}{2}$ -in. gas pipe marked into 2-ft. sections by $\frac{1}{4}$ -in. rivets running through the pipe. Any other method of marking may be used which will not be destroyed by the action of the fire or interfere with the passage of the pipe through the fuel bed. A mark is also placed at the height equal to the distance between the blower and the producer top. This indicates the distance the rod should be forced into the producer. In using the rod, the distance to the top of the fuel bed is first determined. (See Fig. 1.) The rod is forced through the fuel bed until the lower end is on a level with the top of the blower and allowed to remain there for two or three minutes. This is usually all the time necessary for the rod to remain in the fire. On being withdrawn, it will be noted that there are two parts which show up distinctly—one a smoky black extending for several feet, and the other a very hot portion usually from 12 to 14 in. in length. This latter

*Assistant Engineer, Gas Producer Department, Wellman-Seaver-Morgan Co., Cleveland, Ohio.

indicates the incandescent zone. Below the lower point of this zone and the end of the rod, there is a portion not affected by the heat and it should not be very hot. This is the ash zone and should never be less than 6 in. and seldom, if ever, exceed 15 inches.

Between the highest point of the hot portion of this rod and the distance determined to the top of the fuel there will be a space of from 6 to 12 in. This is the green coal zone. If the coal is of a tarry nature, it is possible that this zone will stand out distinctly by a tarry deposit upon the rod which can be readily distinguished from the sooty deposit above this section. The sooty portion of the rod represents the part in contact with the gas.

It is not intended that this method of measuring the fires should be employed more than two or three times per day, depending upon the number of times the fires are cleaned, but this is the only way the ash zone and the fire zone can be measured and the amount of ashes that it will be necessary to remove be determined. If the fires are measured just before the change of turns twice a day, it eliminates all chance for the men to excuse their own indifference by blaming the other shift for trouble which might be of their own making.

HOT OR COLD GAS

The green coal zone mentioned in previous paragraphs may vary with requirements. If it is intended to generate a hot gas, that is, gas leaving the producer at a temperature of about 1200 deg. F., the coal zone should not be allowed to exceed 6 to 8 in. The gas showing when the poke-hole cover is removed will be a brownish-black and a small pilot flame or color cone of about 3 in. in length will appear in the center of the escaping gas. If, however, it is desired to generate what is termed a solid gas, a deeper layer of coal must be carried over the incandescent fuel. This may be anywhere from 8 to 15 in., depending more especially upon the nature of the fuel. Under these conditions, the gas appearing when the poke-hole cover is removed will be a bluish-white and the temperature when leaving the producer may be as low as 700 deg. F. This is by far the richest and best gas for most purposes. The hot gas usually carries a B.t.u. value per cu.ft. of about 150, while the cold gas may have a value of 170 to 180 B.t.u. per cubic foot.

Some operators insist that cold gas will not operate efficiently in open hearth furnaces or other places where it is desired to carry a melting temperature. This is a matter open to some discussion. We know of several open hearth plants in very successful operation using cold gas by preference.

POINTS OF ATTENTION

Some coals have a tendency to become soft and pasty under the action of the heat in the producer. This restricts the passage of the gas, and owing to the fact that the pressure accumulates under the steady blast, the gases will seek channels to break through the resistance of the fuel bed. These points then become excessively hot, melting the ashes and other foreign particles in the coal which form the basis of clinkers.

If the coal in use is of this nature, care should be taken to see that these channels do not form. This can be done by close attention to the stirring and the regulation of the blast, or it may be necessary to change the mixture of the blast, increasing the proportion of

steam to the amount of air blown. This will lower the temperature of the fire and thus considerably decrease the tendency for the fires to clinker. It should be remembered that the change should not be carried to the point where the CO₂ content in the gas becomes excessive or the fires are so cooled that the carbon in the coal is not properly gasified. Either of these items determined a certain amount of loss, but the situation should be considered as a whole and decision made as to whether the stoppage due to clinkering and the extra labor attendant to the same are not more than an offset for the few percentages of the CO₂ or a slightly increased amount of carbon in the ashes.

CLEANING THE FIRES

It is the usual custom to clean the fires two or three times a day, depending upon the amount of coal burned and the percentage of the ash in the coal. It is not necessary that the operation of the producer be discontinued during the cleaning period. The fire should never be lowered more than 8 or 10 in. during one cleaning period, and the coal should be dumped as during the regular period, although usually in smaller amounts. It is better to lower the pressure on the blowers 10 or 15 lb. during this period. If two or more producers are arranged to operate on the same line, the other products should be blown slightly harder during this interval, and if this operation is properly carried out, the entire battery of producers may be cleaned without the slightest effect noticed in operation of the furnaces. During the cleaning period careful attention should be given to any clinker formations that are likely to appear on the side wall. These should be broken loose and the side walls kept clean.

FEEDING COAL

The proper dumping and distribution of the coal charges have a decided bearing upon the conditions obtained in producer operation. The coal should be dumped in as small quantities as can be conveniently arranged and strict attention should be paid to the color and appearance of the gas, which shows whether or not the fuel bed is of the proper thickness.

STEAM REQUIREMENTS

The amount of steam required to blow the producer varies with requirements. If it is necessary to crowd the machine, more aid is needed to burn the increased amount of coal and as the proportion of steam and air must be maintained, it is only necessary to increase the steam pressure until the proper amount of aid is delivered. This in no way affects the quality of the gas if the fires are kept in the proper condition. Gas of just as good quality can be made at 100 lb. pressure as at 15 lb.—only the volume will be greatly increased and it is possible for the fires to get out of order much more quickly. It is difficult to set a definite limit upon the amount of steam required, but as a general thing it is seldom necessary to use more than 40 lb. of steam to get the desired results.

COOLING WATER

In starting a new producer, the top plate has a tendency to run hot and will usually require about all the water that can be applied through the three connections furnished. After a few days the top plate becomes coated with carbon and the quantity of the water can

be considerably reduced. The overflow from the poker is usually sufficient for all purposes and this amounts to approximately 15 to 20 gal. per minute.

If for any cause the water pressure should be lost so that no water will flow through the poker, the producer should be immediately shut down and every effort made to keep the poker cool by means of an emergency line of steam or air. Caution should be exercised in starting the water flowing through the system, because if a large amount of cold water is allowed to strike the poker, there is danger of the point breaking, making its replacement necessary.

The life of a poker tip is from six months to a year, depending considerably upon the condition in which the operator has kept his fires. This tip is a separate point screwed into the main barrel of the poker while the latter is heated to a cherry red color. This method of applying new tips should be used to prevent their working loose under the action of the fire. It is good policy to have a spare poker and trunnion ready for immediate use and the entire poker and trunnion changed if it is necessary to make a replacement during the operating period. This operation should not require more than 20 minutes.

SHUTTING DOWN

In most installations there are periods when the furnace is down for repairs. This time should be taken to clean out the producer completely. The side walls should be cleaned, the blower and blast boxes cleaned out and any mechanical part needing attention should be repaired. This procedure, if carried out, will never entail a great deal of labor and this will be more than repaid by the increased reliability of the machine and the success attained in its use.

Industrial Tuberculosis

Industrial tuberculosis claims more lives annually than are killed in mine fires and boiler explosions, with railroad collisions thrown in. It is chiefly in the dusty trades that this enormous death toll is taken, according to data of the National Tuberculosis Association, received from health experts throughout the country. This organization, the leading agency in America to fight the white plague, is now engaged in a campaign against this menace, culminating in the Red Cross seal sale, by which its work throughout the year is largely financed.

"The country is facing a serious situation in its post-war period," says Dr. Charles J. Hatfield, managing director of the association. "This disease, we have found, claims no less than 150,000 lives a year. Also there are more than 1,000,000 persons in the United States who are suffering from active tuberculosis right now.

"A large percentage of this is industrial disease, and much industrial disease is preventable. Tuberculosis is caused by a germ which spreads from one person to another by spitting, direct contact, or other means. But the strong, healthy man does not have tuberculosis even when he gets the germ. The sound human body can resist it and throw it off. It is generally the man whose lungs have been injured by sharp bits of flying

dust or whose general health has been injured by living or working in hot, stale air who falls a victim.

"That is why the dusty trades have so high a percentage of deaths from lung disease. All mineral products are as a rule subject to preliminary breaking or crushing processes, in connection with which a large amount of finely comminuted dust is produced, and this dust is likely to prove injurious to health."

Dr. Hatfield said no statistics are available to prove that pulmonary tuberculosis is excessively common among men employed in smelting and refining. The practical problem, he said, concerns the control of metallurgical smoke, which consists of three distinct substances—gases, flue dust and fume. Of these three it is only the flue dust that is of serious importance, consisting of small particles of the different ores, fluxes or fuel.

"The hygiene of smelting and refining is of extreme complexity," he said. "In the absence of an extended scientific inquiry into the subject at the present time definite conclusions cannot be made."

Dr. Hatfield called attention to a report prepared by Dr. A. J. Ianza, of the United States Public Health Service, dealing with the dust problem in industry. This, he said, sums up the medical viewpoint clearly and accurately, and is in part as follows:

"Dust is not a disease, but it is the cause of disease. Any hard, sharp rock dust when breathed into the lungs irritates and cuts them, making small scars. Besides, because of the constant irritation, the lungs become inflamed, and consumption is likely to develop. The constant irritation of the lungs weakens them and at the same time gives the seeds of consumption a good chance to grow. The dust breather is more likely to fall a victim to the careless spitter than the man whose lungs are sound. Working in dust, like exposure, is at times unavoidable, but a great deal if not most of the dust breathing is due to carelessness on the part of the miner himself, who does not realize the danger of so doing, or, if he does, is indifferent to it.

"The number of deaths from lung diseases among metal miners is much greater than among coal miners and is probably ten times greater than it ought to be. What can the miner do to avoid breathing dust? Water drills are being used more and more. In dry drilling with machines it is possible to lay the dust by water lines or by using a squirt gun and water from a bucket, but often men drill with the hole dry rather than turn on the water, because it spatters on them or makes the place sloppy. If you are drilling overhead and the water has to come back on you, wear a rubber hat and boots, and if necessary a rubber coat. This is a bother, but it is also a bother to observe all the rules of 'safety first' which save lives. A man working where there is much dust should wear a respirator if possible, and see that the respirator is in good condition. Respirators are clumsy and more or less of a nuisance, but it is better to wear one than to have consumption. Do not breathe hard-rock dust day after day, because if you do it will disable you in time. Men who can 'eat rock dust'—like the men who can 'breathe gas'—die young."

National Tuberculosis Association,
New York City.

The Booth Electric Rotating Furnace

BY CARL H. BOOTH*

AS A general rule, the quantity of non-ferrous metal melted at one time, or at one heat, is less than the quantities involved in the melting of steel and iron, and, therefore, smaller sizes of furnaces are desirable. To meet the requirements of the small foundry, as well as the large foundry, and the smelters and refiners, Booth furnaces are built in the following sizes:

Rated Holding Capacity	Maximum Holding Capacity
250 lb.	350 lb.
500 "	750 "
1000 "	1500 "
2000 "	2500 "
3000 "	4000 "

There are many small plants where heats of 50 to 350 lb. are required, and the smallest size furnace mentioned above answers the purpose with great economy, whereas larger furnaces, to operate efficiently, must produce more metal than is needed. Further, there is also a great disadvantage in trying to pour a ton of brass into small castings and keep the metal hot. We know of a large company which has a 1-ton electric furnace; it takes 50 min. to pour a heat into castings, and it is difficult to do it in that time. Also the great variety of mixtures made by many small foundries requires a small, efficient unit, from which "short" heats can be taken, producing great flexibility of operation.

FIG. 1. CROSS-SECTION OF BOOTH ROTATING FURNACE

On the other hand, smelters and refiners frequently require furnaces of relatively large holding capacity, which will turn out a considerable amount of metal daily.

Fig. 1 is a cross-section or diagram, illustrating clearly the principle of construction of the Booth electric rotating furnace. As will be noted, the furnace revolves on rollers, and is carried by two cylindrical tracks. The rollers are driven at the proper speed by a motor, so as to rotate the shell at a speed of two revolutions per minute. No gearing is required on the tracks. The current is carried to the electrodes by means of short pieces of flexible cable, which connect to the above-mentioned track, and the current is supplied to the track by shoes which press against them and form a sliding contact. The electrodes are regulated by screws shown, and on small furnaces are entirely hand-operated, but on the larger furnaces automatic electrode control is used, thus doing away with the necessity of close watching on the part of the operator. In the small furnaces, the door is in one end only, but in the larger furnaces both ends are provided with a door.

Fig. 2 is a photograph of a rear view of a 250-lb. Booth electric brass furnace, in the foundry of Leitelt Bros, Chicago. This shows the charging door open ready for charging. The latch which holds the door

FIG. 2. REAR VIEW, SHOWING CHARGING DOOR

shut when the furnace is charged will be noted and, also the electrode projecting through the door. A door of similar type with electrode projecting through it has been in use a considerable period in the construction of the Booth-Hall steel melting furnace. The contact shoes are shown in this view pressing against the track.

Fig. 3 shows the same end of the furnace after it is charged and the furnace is ready to run. The flexible cables from the track to the electrode holder are shown, as are also the water-cooling connections for cooling the electrodes. It is not necessary to open the door until after the heat is poured. The door is then opened for charging.

Fig. 4 shows a side view of the furnace. The cable supplying the power to the furnace is shown on both sides, coming from conduits in the floor to the bronze shoes. These are the only connections necessary to carry the electricity to and from the furnace. The operator is shown at the left regulating the flow of the current by means of a hand-wheel. The contactors are shown on the switchboard, together with push-button control for starting and stopping the furnace.

Probably the most important of all factors in reliable and efficient furnace operation is the lining. Especially is this true with the melting of non-ferrous metals, where a lining with many joints will have a decided tendency to absorb metal. In order to overcome this

FIG. 3. CURRENT CABLES AND WATER-COOLING CONNECTIONS

*Extracts from paper delivered before A. I. C. E., June 18, Cambridge, Mass.

difficulty the lining provided with the Booth furnace is made with as few joints as possible.

In lining the furnace the electrode supporting mechanism at either end of the shell is removed by simply unbolting it from the end plates. These are made as a unit and in taking them off they do not get out of adjustment or out of line, and therefore do not require any adjusting when put back in place. The shell is then lifted off the rollers by suitable hoist or crane, just as if it were a barrel, and is turned on end so that the end plate of the furnace shown in Fig. 2 can be unbolted and removed from the shell.

Fig. 2 shows to some extent how this lining is made. The door is made of one solid piece of brick with a hole in the center through which the electrode projects. The cylindrical part of the furnace is made of two cylindrical tiles, which fit together with a tongue and groove joint in the center, this joint being filled with heat-resisting cement. The ends of the furnace are each lined up with four special bricks joined together with cement and cemented to the tiles. In this way we really have a large crucible electrically heated, but with walls of considerable thickness and a minimum number of joints. Further, this lining does not require a brick mason to install it, but can be put in with common labor. This special brick lining is backed up with a layer of heat-insulating material, so that when

has proved to be very low. Due to the active mixing action of the rotation, the heat is applied to the turnings and borings in such a uniform manner that there is no local overheating, and a quick melt with low metal loss is obtained.

In melting ingots and heavier brass scrap, a heat will average from 30 min. to 1 hr. in length of time, depending upon the kind of metal poured and the size of the charges. A 300-lb. charge of copper ingots requires about 1 hr. to melt and pour, while a 300-lb. charge of yellow brass requires about 40 min. The shrinkage with yellow brass ingots averages about 1 per cent and on red brass and high copper bronze under 1 per cent. With the furnace hot the power consumption will run from 250 to 350 kw.-hr. per ton.

One heat was made with a charge running about 50 per cent zinc and 40 per cent copper, totaling 250 lb.; 249 lb. of metal was poured and the power consumption was 240 kw.-hr. per ton. This was in the latter part of the day, when the furnace was hot, and the metal charged was all clean metal. The ladle was weighed as it was brought to the furnace, and then weighed after the metal had been poured into it. Great care was taken on the part of the operators not to overheat the metal, and this is simply an indication of what results are accomplished where sufficient attention is given to melting. The heat following was a charge of 225 lb. of red brass ingots, from which 224½ lb. of metal was poured.

With furnaces of this type the graphite electrode is to be preferred, due to its greater conductivity, which permits the use of the smallest size of electrode practical for the current to be carried.

The electrode-supporting mechanism has been so designed that it not only permits of adjustment in case electrodes are slightly out of line, but at the same time serves to protect the electrodes from breakage, due to the accidental falling of bars or other material against the end of the furnace.

Great difference of opinion still exists among operating engineers as to the proper power factor best to be used in connection with electric furnace loads. With small furnaces of the type just described, our judgment is that as low a power factor should be adopted as can safely be permitted with the conditions met with at the point of installation. This can be varied to suit different conditions by modifications in the design of the equipment. If a power factor as low as 70 per cent is permitted, the result will be that the furnace operator need not stay at the electrode hand wheel control to any great extent, but may be employed in getting his charge ready for the next heat, making suitable records and other miscellaneous duties. If, however, a higher power factor is required, the furnace can be readily operated, but will require more attention on the part of the operator unless automatic electrode regulators are provided.

It is our judgment that in case of installation of a battery of small furnaces, providing a sufficient advantage in power rate could be obtained by obtaining a higher power factor than 70 per cent, it would be best to install automatic electrode regulators. There would also be compensation in reduced labor cost due to the fact that one man could take care of a large number of furnaces under such conditions.

Simplicity.—In designing this furnace the aim has been to produce a furnace which was efficient enough so

FIG. 4. MOTOR DRIVE AND SWITCHBOARD CONNECTIONS

the furnace is at working temperature, the temperature on the outside of the shell is so that the hand can be placed upon it. The time required for relining this furnace is 8 to 12 hours.

In melting down turnings, borings and grindings with a hot furnace, 30 to 40 min. is required per charge. With the small furnace shown the power consumption may be as low as 240 kw.-hr. per ton; the average would be between that and 300 kw.-hr. per ton.

With yellow brass turnings and borings which are fairly clean, but on which no attempt has been made to remove any contaminating material, heats have been run with a total shrink of 1½ per cent. These borings, when charged, were in the same condition as received from the seller. Of course the percentage of shrink will depend on the amount of oil, dirt, iron and other extraneous material present, but the actual metal loss

that it could be built in small sizes suitable for adaption by the small brass foundry; at the same time such a furnace must be strong and rugged in construction, have few parts and be simple electrically, not requiring the supervision of an electrical engineer or other expert.

Flexibility.—Furnaces of this type can be built in large sizes and offer as many advantages to those plants requiring a large tonnage of brass as is true with a small foundry. The convenience of the operator has been particularly kept in mind, also the ease with which repairs can be made and of incorporating into the construction of the equipment all details which will eliminate shut-downs due to either mechanical or electrical details.

Economy in Handling.—The charging door of the furnace is located at the opposite point from the tapping. If a battery of furnaces is installed in a plant, it is much more convenient and economical both in the labor cost and in the handling of materials to have the charging operations carried on at one end of the furnace, entirely separate from the tapping and pouring. This also saves in floor space, as the furnaces can be located very close together under such arrangement.

Economy in Pouring.—In pouring the furnace the tap-hole is opened without coming in contact with the metal, and as the furnace is rotated by the motor, the metal pours out and can either be collected in ladles or be poured directly into molds or ingots brought up to the furnace by approved mechanical means. It is also entirely practicable to pick the furnace up off its rollers and carry it by suitable electric traveling crane over to the molds and pour directly into them. This method would be especially adapted for pouring ingot molds or the casting of slabs. After the furnace was poured it would then be returned and set on the rollers, charged and started in operation. Since there are no cables to be disconnected or other electrical connections made, this can be readily done.

Simplicity in Electrical Connections.—The absence of cverhanging cables and the simplicity of the electrical connections is one of the great advantages of this furnace. This is readily apparent and is referred to again simply for emphasis.

Ease of Making Repairs.—Where a large number of Booth furnaces are installed in one plant it is advisable to purchase an extra furnace shell, which could be kept lined up ready for service. This will be particularly valuable in the case of a plant operating on 24-hr. basis, as it would save time in shut-downs. The method proposed would be: As soon as the lining of one of the furnaces in use was worn out, the furnace needing a new lining would be lifted off its rollers and the spare furnace set in place, immediately charged and started up without losing more than half an hour's time altogether. The furnace shell which was removed could then be allowed to cool down and new lining placed in it ready for further use.

Low Shrinkage Loss.—The important reason why electric furnaces are being adopted by plants melting brass is because of the large saving made in metallic shrinkage. The construction is especially noteworthy in this respect, and all advantages due to the movement of the metal are secured by the rotation.

Freedom From Explosions Due to Gas Pressure.—Where mixtures are used which might result in the formation of much gas pressure in the furnace, the charging door or doors need not be luted up so as to permit of the escape of the gas pressure without blow-

ing out the end of the furnace, as is understood to have been the case in a number of instances where sufficient openings have not been allowed. This can also be accomplished in a very simple manner by leaving the tap-hole open for a short time in case it is desired to burn off the oil and dirt prior to the melting of the charge. In other words, with a charge of turnings and borings which are dirty and oily, the furnace can be left stationary with the tap-hole open, the furnace being turned around on its rollers so that the tap is located at the top position instead of at the bottom, which would be the position in pouring. This open tap permits the burning oil and fumes to escape. As soon as the operator notes that metallic vapors are coming off, the tap can be plugged up with molding sand and the rotation of the furnace started.

Low Cost of Operation and Upkeep Charges.—The complete rotation of the furnace results in more even wear of the lining, a greater absorption of heat by the metal from it, which naturally results in an improved power consumption. These factors help to bring down the cost of melting and upkeep charges.

Since this type of furnace is new, and there has been only about a month's operation from which to obtain operating data, proof from actual records of just what the cost of these items will be is not at hand. The important fact remains, however, that the small furnace described in this paper was successful from the very first heat, has been in daily operation without shut-down from the time the power was first turned on, and the lining does not show any appreciable wear. It is expected that after a suitable length of time has elapsed the power consumption and other data obtained will show that there is a great advantage to be obtained in rotating the furnace completely.

Uniform Mixing of Charge.—The rotation of the furnace not only preserves the lining and secures a low power consumption, but at the same time serves to mix the metallic charge, making it more uniform without requiring much supplementary stirring. Except in the case of mixtures with high lead content, the rotation of the furnace will sufficiently mix the charge so that it is not necessary to stir it either in the furnace or in the ladle. This is quite an advantage and results in a more uniform product.

Standardization to Meet Prevailing Electrical Conditions.—In the past the construction of electric furnaces has been along lines which require the use of special electrical appliances and equipment. This furnace is a departure. It is entirely practical to operate it using the ordinary 110-volt single phase service which can be obtained from most public service companies.

Standardization of Mechanical Details.—All details of the furnace equipment are rapidly being standardized so that quick shipment can be made of furnaces, as they are shipped completely assembled and the production and installation is a simple matter. In case automatic electrode regulator control is desirable, it should be pointed out that only one regulator would be required, and this would reduce the investment cost materially.

Furnace Can Be Designed to Operate 3-Phase.—In the design of large size furnaces of this type, we have plans perfected for completing the equipment so that it can be operated using either 2 or 3 phase alternating current instead of single phase. This would be important in many cases where public service companies are not in position to handle single phase loads over 75 k.v.a.

The Vicious Postal-Zone Law

BY ARTHUR CAPPER
United States Senator from Kansas

IT HAS been argued that the postal-zone increases apply only to the advertising sections of magazines. This is perfectly true as a statement of the mere words of the postal-zone law.

It is not true as a statement of facts.

For a periodical or a newspaper is a unit from cover to cover. It is one unit of bulk that is never broken. The argument that the increased postage merely affects advertising is virtually the same as if it were argued that the postal-zone legislation had provided that the upper half of a magazine should pay postal-zone rates and the lower half flat rates. It would be a mere bookkeeping separation that would not in the least affect the postage cost to the reader, for the reader—who is the ultimate consumer—takes the magazine as it comes, and the cost of the magazine is its cost as a unit, and its postage cost to him is its entire cost as a unit, no matter how ingeniously or intricately one may subdivide the component parts.

There is one other important factor also, which I feel many sincere and ordinarily keen-minded citizens have overlooked, and that is, that the magazine and newspaper differ from every other commodity—if you wish to consider newspapers and magazines as merely commodities—in the fact that it is the only “commodity” that is sold to the consumer at less than its actual cost of manufacture!

And a newspaper or magazine is the only “commodity” of which this is true.

Now as to the advertising and whether it should pay a higher rate than the body of the magazine. I think I have answered half of that question when I point out that the periodical and newspaper are the only products that are sold for less than their cost of manufacture, and that this fact is made possible by the advertising. Advertising is nothing but a bulletin board—the bulletin board of our economic, wealth-producing, business life.

Advertising is the one great factor in modern wealth production that enables wealth to be distributed almost instantaneously; a generation or so ago the same result could not have been accomplished without years of hand-to-hand selling and expensive, slow, personal salesmanship. You, as a thinking citizen, know what any restriction upon advertising would do to the wealth production of this nation. Congress itself saw this, and when means of war taxation were being carefully discussed and every channel was being developed, it was deliberately decided that the destructive economic effects that would follow the taxation of advertising would be too great and too dangerous to attempt.

Now then, as to the allegations of the cost of transmission of this second-class matter through the mails.

The figures upon which the absurd allegations of second-class deficits are made were compiled by the Post Office Department in 1908 and 1909—eleven years ago! So unreliable were they even then that when the U. S. Postal Commission, headed by the Hon. Charles E. Hughes, investigated them two years after their compilation, they were officially discredited as being no indication of what the costs were for the various divisions of second-class matter! Moreover,

the Post Office Department since that date has taken pride in stating that it has in enormous and basic ways cheapened the postal cost of second-class matter.

The most unfortunate part of this postal-zone legislation is that it is an insidious and dangerous attempt to set back postal history seventy years and re-establish the universally condemned principle of postal cost determining the postal rates. It abolishes the sound postal principle of equal postage to all parts of our nation. The rural free delivery—one of the most vital and important postal functions—is conducted at almost a total loss, and if this vicious and unsound cost principle is once established the demoralization of our splendid postal principles is only a matter of logic and time.

Who Are Entitled to Compensation

BY CHESLA C. SHERLOCK

EMPLOYERS are often puzzled to understand the meaning of the compensation acts, especially as they apply to the coverage of workmen within their employ. They are surprised, for instance, to discover that many workmen within their employ are not entitled to the benefits of this legislation, and many other employers are greatly agitated when they discover that they have been paying a premium for the risk of employees who are not and should not be considered as risks under the workmen's compensation acts.

Generally speaking, the purpose of the compensation acts is to provide compensation for those workmen who are injured as the result of an accident “arising out of and in the course of” the employment. This necessarily excludes a good many workmen who receive injuries by accident that do not arise out of and in the course of the employment, but it does not relieve the employer of the necessity of carrying them under an insurance policy as a risk for the reason that they doubtless are the character of employees who are likely to be injured in a compensable accident and be entitled to the benefits of the law at any time.

Instances where workmen are not entitled to compensation even though injured by accident may be mentioned briefly. If a workman is injured while on his way to or from work, he is not entitled to compensation, as the courts do not deem that the injury arose out of and in the course of the employment. If he is injured as a result of horse play or malicious intent of another to inflict bodily hurt upon him, he is not generally entitled to compensation. If the injury is due to his own willful misconduct he is likewise not entitled to the benefits of the workmen's compensation acts.

CERTAIN CLASSES EXPRESSLY EXCLUDED

There are certain classes of workmen, however, who are never entitled to compensation and they are expressly excluded from the benefits of the law by the statute itself. Yet employers go on year after year laboring under the false impression that it is necessary to include them in their list of risks and keep on paying premiums upon such risk, when they are plainly merely putting the money in a hole in the ground.

In the first place, every employer should procure a copy of his State statute and find out just what class of employees is included in the coverage of his law, and pay insurance premiums only on those risks which are

entitled to compensation in case of injury under compensable circumstances.

In some States he will find that only those who are engaged in a hazardous occupation are entitled to compensation if injured. In many shops and factories this will materially lessen the number of risks which the employer has to carry.

For instance, all clerks and clerical help of whatsoever nature are not covered under the expression "hazardous occupation." The courts have held this repeatedly, yet I personally know many employers who habitually paid premiums on the risk of these employees because they thought they would be entitled to compensation in case of injury.

CASUAL EMPLOYEES GENERALLY NOT ENTITLED TO COMPENSATION

Casual employees are not generally entitled to compensation. This generally includes all odd-job labor, such as window washing. The point to be kept in mind is that it is the character of the work being done that determines the element of liability and not the character of the employee. A man may be a casual employee and be engaged in a compensable occupation. He would not, of course, if hired for one job as a casual employee, be entitled to compensation if injured, but he may be a regular employee who is engaged in casual employment at the time of the injury. Some courts have said that even he is not entitled to compensation because it is the nature of the work being done that determines the test of liability.

In instances where the work is exceedingly dangerous and the employer has formulated strict rules as to the way in which the work has to be done, and enforces those rules in case of violation by the discharge of the offender, a subsequent disregard of such rules by an employee resulting in injury to himself will relieve the employer of liability, as the workman is deemed to have been guilty of misconduct such as to deprive him of his rights under the law.

Employees engaged in domestic service or those engaged in agricultural pursuits of any nature, even though working constantly with farm machinery, are not covered under the compensation acts, unless by express wording.

Gardeners and lawn keepers around factory premises then are not entitled to compensation. Those who work even at hazardous occupations, if it be an "agricultural pursuit," are not covered unless the statute expressly says so.

INDEPENDENT CONTRACTORS NOT COVERED

Workmen who are working as independent contractors are not covered by the compensation acts and no premium need be paid on their risk. This does not necessarily exclude all time and piece laborers, but it does exclude all those who are taking work to do wherein the employer has no control as to the means in which the work is done, having control merely as to the general result of their labor. In such cases the court deems these employees to be independent contractors and relieves the employer of liability in case they are injured while at work.

If the workman is engaged in work outside the usual course of the trade and business of the employer, he is not entitled to compensation under the compensation acts.

All those who stand in a representative capacity or

who are executives in the business are not workmen within the sense of the compensation acts and cannot recover compensation no matter how hazardous their work may be. A case is recalled where a faithful bench worker was made a vice-president in the company in order to "fill out" the list of officers and as a reward for long and faithful service. Upon injury, he was denied compensation.

Employers by paying premiums only where they are needed and in carefully checking over their lists from time to time can save themselves and their companies a great deal of premium money that is otherwise being wasted. And there is a surprising lot of it in some quarters due to a failure properly to understand the compensation laws.

House Considers Tariff on Graphite

Despite the discouraging prospects of obtaining action by the Senate, the Committee on Ways and Means of the House of Representatives has held two hearings on a bill placing duties on imports of graphite. Strong protests against any tariff were made before the committee by crucible manufacturers and other consumers of imported graphite.

The bill which was before the Ways and Means Committee provides a duty of 2c. a lb. on all imported amorphous graphite; 3c. a lb. on all crystalline, lump, chip, and all crystalline graphite which will not pass through a $\frac{1}{4}$ -in. mesh; 6c. a lb. on all crystalline graphite that will pass through a $\frac{1}{4}$ -in. mesh.

The first rate of duty mentioned affects principally the graphites imported from Mexico and from Korea. The second rate applies more particularly to the better grade of Ceylon graphite, while the last named rate affects Madagascar and Canadian flake and Ceylon dust. Practically all Canadian graphite and probably that of Madagascar flake would be excluded from importation by the bill, it is admitted.

Substitution of the electric furnace for crucibles would be forced by the bill, according to Malcolm McNaughton, the chief chemist of the Joseph Dixon Crucible Co., who testified before the committee. As a consequence, he argued, producers of domestic graphite are injuring their own interests in urging the passage of the bill, as they are likely to destroy the principal market for their product.

A. B. Conklin, who appeared in behalf of the Alabama graphite industry, does not share the view of Mr. McNaughton, and insists that it is in the interest of the American people as a whole to have developed this country's supplies of graphite, which he contends can be used just as successfully as the foreign product if manufacturers will undertake sympathetically to make slight changes in their practice.

A plea that stocks of graphite purchased abroad by America and which cannot be moved because of lack of shipping should be exempt from the duty imposed in the bill was made by Charles Pettinos, a New York dealer in both foreign and domestic graphite.

Fundamental data concerning the amount of graphite produced in this country as well as the amount imported were presented to the committee by George Otis Smith, the director of the United States Geological Survey. Mr. Smith also gave a detailed description of the uses to which the various classes of graphite are put in industry.

Synopsis of Recent Chemical and Metallurgical Literature

British Electrodes

Prior to the war, the consumption of electrodes in Great Britain was rather meager, and that little easily supplied by America, Sweden and Germany. By 1915,

VIEW OF MAIN BAY, ELECTRODE CO. OF SHEFFIELD

the Electrode Co. of Sheffield, Ltd., was organized, and built works at Meadow Hall for a capacity of 2500 tons per annum of amorphous carbons. Experimentation has gone forward continuously with production, however, and at present the company is engaged in extensive additions following ideas developed in the last year or so, which will increase its production to 7000 tons yearly.

The company's main building, some 320 by 100 ft. in area, is served by three 5-ton traveling cranes, as is shown in the accompanying illustration, taken from the *Iron and Coal Trades Review*. Raw anthracite is first burned in muffle- or retort-type furnaces, and then delivered to a storehouse containing also scrap electrode and retort carbon stock. These materials are then crushed, elevated, and ground in a Newell ball mill, the

discharge being carefully graded. Mixing is effected in a battery of four steam-jacketed runner mills, each driven by a 45-hp. motor.

Molding is done in a pit immediately below the runner mills; the molds themselves are first dipped in heated oil, and rammed full of the carbonaceous mixture by a portable tamper. A crane then delivers the filled molds to the press plant, comprising two hydraulic presses of 500 and three of 300 tons capacity, each with a separate water and pumping system. After pressing, the molds are stripped by a further stroke of the press, stood on end to dry, and finally burned in a battery of ten coal-fired furnaces, the time required being about three weeks.

Gas Combustion Chart.—At the July, 1919, meeting of the Société Technique du Gaz, Mr. GREBEL presented an important contribution on the influence of the burner on the efficiency of industrial heating by gas. He also gave the chart shown herewith, by which one can determine the influence of the percentage of air on the thermic potential of gas heating and of the specific consumption of the burners. The chart applies to the combustion of fuels composed of hydrogen, carbon and oxygen with an excess or deficiency of air. The oblique dash lines giving the proportions of air supplied to air required were determined on the assumption that all the carbon dioxide results from combustion and the nitrogen from the air supplied. The pure combustibles, methane, carbon, carbon monoxide, are represented by the full lines and hydrogen by the bottom horizontal line; the complex fuels, city gas, heavy oil, benzol, producer gas, water gas and blast-furnace gas, are represented by the dot and dash lines. The part at the right of the zero vertical line is for excess of air and the part to the left for deficiency in air.

From the analysis of the gases of combustion by an Orsat apparatus, it is easy to determine by the chart the quantity of air furnished and utilized, and the quantity of air necessary for perfect combustion.

Le Génie civil, Aug. 16, 1919, pp 152-154.

GAS COMBUSTION CHART

Recent Chemical and Metallurgical Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Smelting Process and Apparatus.—F. H. FRANKLIN HAMPTON of Sewell, Rancagua, Chile, has devised an apparatus with which it is possible to smelt flotation concentrate or finely pulverized ore continuously without the necessity of briquetting the concentrate or ore. Pulverized coal or oil is used as fuel. The apparatus is shown in vertical section in Fig. 1, Fig 2 is a horizontal section along line B-B of Fig. 1, and Fig. 3 is a fragmentary vertical radial section taken along line C-C of Fig. 2. The pulverized ore and fuel are blown into the smelting chamber (a) through the vertical tuyere (c). The proportions of air, fuel and charge are so adjusted that complete combustion of the fuel will result from the combined oxidizing effect of the air and the charge. The ore is

fed in at (n) and the pulverizing coal and air blast at (m). If oil is used as fuel it is fed through pipe (p) and nozzle (o). The air blast is heated to about 500 deg. C. by being drawn through ducts (j) and heating jackets (h). The reactions which take place are similar to those taking place in the ordinary blast-furnace in that the resulting products are a slag and a matte, which collect in hearth (b) and are then tapped through spout (q) to the forehearth (r), Fig. 3. The products of combustion pass through the flues (d) and (e) to a stack. (1,315,551, Sept. 9, 1919; assigned one-half to W. W. Stenning of London, England.)

Process of Recovering Platinum Metals.—WILLIAM C. FERGUSON of Garden City, N. Y., treats electrolytic

copper slimes for the recovery of metals as follows: Roast in the presence of sulphatizing agent; then leach with water, thereby dissolving copper and silver sulphates; the residue is lixiviated with diluted sulphuric acid and the dissolved silver subsequently precipitated as chloride. The insoluble residue from these operations, containing gold, silver, platinum, palladium, tellurium and traces of copper and lead, is treated with aqua regia. Gold is dissolved and subsequently separated from solution by precipitation with ferrous sulphate. The insoluble silver in the residue is recovered by solution in sodium thiosulphate, the residue being returned to the smelter. The acid solution, which contains practically all the platinum and palladium from the original slime, also antimony, tellurium and traces of gold, lead and copper, is saturated with sulphur dioxide and heated to about 200 deg. F. until tellurium precipitates in appreciable quantities. All the platinum, palladium and some cuprous chloride are thus precipitated. This precipitate is separated by filtration, treated with concentrated sulphuric acid, heated until the acid fumes, the tellurium compound present is decomposed and the volatile portion thereof expelled from solution. Crystals of sodium nitrate are added to the hot solution, thereby oxidizing the tellurium and dissolving the palladium. This solution is diluted and filtered, and the contained palladium precipitated by ferrous sulphate substantially free from tellurium and copper, but containing traces of gold and platinum. The residue from the sulphuric acid treatment, containing the platinum and some gold, is dissolved with aqua regia, and the solution is then saturated with ammonium chloride. Ammonium platonic chloride is precipitated and removed by filtration, the filtrate being returned to an earlier stage of the process. Metallic platinum is obtained by reduction of the ammonium platonic chloride. (1,315,660, Sept. 9, 1919; assigned to Nichols Copper Co. of New York.)

Art of Melting Metals.—WILLIAM H. BRISTOL of Waterbury, Conn., patents a process for preventing the oxidation of metals when these are melted in a crucible, electric resistance or other suitable furnace, which consists of providing over the surface of the metal an envelope of steam. In an electric-resistance furnace the steam also prevents the oxidation of the resistor. (1,315,206, Sept. 9, 1919; assigned to the Bristol Co., of Waterbury, Conn.)

Process for Treating Copper Ores by Sulphatization and Flotation.—NIELS C. CHRISTENSEN of Salt Lake City, Utah, has devised a means of recovering copper from oxidized ores or from sulphide ores that are partly oxidized. The process consists of treating the moist pulverized ore, in the absence of air, with sulphur dioxide gas which is free from sulphur trioxide at a temperature somewhat below the boiling point of water. The reaction under these conditions results in the production of cupro-cupric sulphite and cupric sulphate. This reaction is carried far enough to coat the surface of the mineral particles. The cupric sulphate is precipitated in the diluted pulp by the addition of CaCO₃, and the pulp treated in any type of flotation machine for the recovery of the copper. (1,316,352, Sept. 6, 1919; assigned to Metallurgic Improvement Corporation of Salt Lake City.)

Process for Treating Ores and Concentrates.—MELVILLE F. COOLBAUGH of Golden, Colo., has devel-

oped a process for the treatment of ores or concentrates containing gold, silver, copper, lead, iron and zinc, for the separation and recovery of these metals. The ores or concentrates containing sulphides are roasted, thereby changing copper, lead, iron and zinc compounds to oxides. Gold and silver either remain unchanged or are changed to metals. The roasted minerals are discharged into another furnace and brought into contact with the hot gaseous products from the first furnace which contain sulphur dioxide. This furnace is maintained at a temperature between 450 and 850 deg. C. Under these conditions, the oxides of zinc, copper and lead and any silver present as chloride are changed into sulphates. Iron oxide, metallic gold and silver remain unaffected. The product is treated with water, the sulphates of zinc, copper and silver being dissolved and the solution electrolyzed for the recovery of the copper and silver. The zinc solution is purified and electrolyzed for the recovery of zinc. The insoluble residue from the water leach containing lead sulphate, iron oxide and metallic gold and silver is smelted for the recovery of gold, silver and lead. (1,315,761, Sept. 9, 1919; assigned one-half to J. Burns Read of Vermilion, S. D.)

Admixture of Metals or Substances for Alloy—EDMUND GODFREY BURR of Montreal, Canada, has devised an apparatus whereby an alloy can be conveniently made in which one of the constituents of the alloy is volatile at the temperature of the melting point of the other constituent. The apparatus con-

sists of the crucible (2) and the retort (3). The metal of the higher melting point is contained in the crucible and the volatile substance is contained in the retort. The whole apparatus is placed in the furnace and the volatile substance is driven down through the center shaft (4) into the molten metal. This method allows for intimate mixture and produces a uniform alloy. (1,315,208, Sept. 9, 1919.)

Metallurgical Furnace.—WALTER O. BORCHERT of Austinville, Va., has designed a rotatable valve or damper for the flue system of a zinc-roasting furnace. This valve in the position as shown at (A) in the

figure permits charging of ore or fuel through chute (30) or connects flue (11) with the atmosphere; in position shown at (B) the valve connects flue (11) with flue (14) and thereby with main flue (10). In an intermediate position air can be admitted from

without the furnace through flue (14). The valve (15) is cylindrical, is made of refractory brick, and consists of a cylindrical shell, and circular end enclosures. The valve rotates on the end flange, being supported by rollers (16). The valve is rotated by chain (23) at each end which is bolted to end flange, motion being carried by sprockets (24) on shaft (25) by means of worm and nut shown at (26) through shaft (27), to which is attached a hand wheel. The functions of the valve are as follows: In position (B) to allow the passage of volatile products from the combination chamber (C) to the main flue (10). In position (A) to permit carbon, soot and (or) reducing gases to be expelled to atmosphere from freshly ignited charges, thus making practical the use of coal which would be otherwise unsuitable, because soot would blacken the oxide, and the carbon and reducing gases would interfere with the oxidation of zinc to zinc oxide. Also to expel to the atmosphere volatile metals such as cadmium and any water vapor that may be formed. Finally, to permit charging into the combustion chamber of the furnace, and at the same time prevent the entrance of air, gases and dust into the main flue. In an intermediate position a regulated amount of air may be admitted to the main flue. (1,316,267, Sept. 6, 1919; assigned to New Jersey Zinc Co.)

Electrolytic Process.—WILLIAM E. GREENAWALT of Denver, Colo., introduces sulphur dioxide into an electrolytic tank during the electrolysis of impure copper sulphate solutions containing ferric sulphate. This ferric sulphate is reduced to ferrous sulphate, thereby increasing current efficiency, producing sulphuric acid and preventing the formation of copper sulphate at the cathode as the result of the reaction of ferric sulphate on metallic copper. The reduction of polarization lengthens the life of the insoluble anodes. The effectiveness of the process depends on the thorough association of the sulphur dioxide and the electrolyte, which is accomplished in the apparatus. A stirrer is located between the cathodes and the anodes. The gas and the electrolyte are brought into intimate contact by mechanical agitation in an auxiliary tank. (1,314,742, Sept. 2, 1919.)

The Mitchell Screen

THE Mitchell electric vibrating screen has been perfected during the last two years by Mr. B. A. Mitchell at the plant of the Utah Copper Co., Garfield, Utah. An upward rotary motion is imparted to the screen by means of an electric motor mounted eccentrically, with the result that 3600 revolutions per minute are obtained. The motor is protected from dust by the tubular casing A. The larger cross section at center encloses the driving motor (B), the smaller cross sections at either end enclose the ring oiling bearings (C) and the ball cages (D). The casing itself is cast in two sections which are rigidly bolted together by means of bolts (E), clamping securely the motor stator between the inside faces of the casing.

The mechanism is held firmly to the main screen frame by means of a steel strap (F) which encircles the middle circumference of the casing. The mechanism rests at its contact with the screen frame in a ball and socket joint (G), the convex portion attached to the vibrator and the concave portion attached to the screen frame. By means of this strap and joint the whole mechanism is free to move in any direction about this joint (G) as a center.

UNDER VIEW OF SCREEN AND MOTOR

A long shaft (H) runs through the center of the machine and is supported by the ring oiling bearings (C). At the center of the shaft is keyed the rotor (B) and at each end of the shaft (H) is keyed the hard fiber cylindrical ball cage (D), having radial bored round holes (I) slightly larger than the diameter of the balls (J) arranged as shown in section at left of drawing.

Encircling the fiber ball cage and pressed tightly into the tubular casing (A) are the hard steel ball races (K). In operation one or two adjacent rows of holes are filled with balls in the ball cage at each end of the shaft (H). Any particular row of balls at one end of the shaft is counterbalanced by a similar row of balls at the other end of the shaft, but the two rows are 180 deg. apart with reference to the circumference of the shaft.

When the ball cage is rotated by the motor, centrifugal force causes the balls to travel to the inside periphery of their respective races with such force that gravity is reduced, and the mechanism being free to rotate at its center, at the ball and socket joint, an eccentric motion is produced at either end of the mechanism.

This motion may be roughly illustrated by taking hold of a pencil at its center by the thumb and first finger of one hand, and with the other hand moving one end of the pencil in a slightly circular path.

The vibrating motion of the mechanism is positive

CROSS-SECTION OF ROTATING MECHANISM

and is at its maximum at the ends, diminishing to practically zero at the center of vibration. The operation is very quiet. By varying the number of rows of balls or number of balls in a row in the ball cage at each end of the shaft, the strength of vibration can be accurately regulated. The vibrating motion is that of a compound or double conical pendulum acting on a horizontal axis.

It is in the production of this motion that lies the revolutionary character of the Mitchell screen and that accounts for its superiority. By it the upward drive of mesh against screening material is made possible, supplemented by the backward tossing that does so much toward thoroughly segregating the material.

The Stimpson Equipment Co. of Salt Lake City is the manufacturing agent.

New Type of Direct-Current Motors and Generators

In a type of commutating pole direct-current motors and generators known as type E, which has just been introduced by the Allis-Chalmers Manufacturing Co., the machines are not only rugged and compact, with excellent operating characteristics, but the many details which contribute to accessibility, reliability and safety have been thoroughly worked out.

This line includes the following standard ratings:

Continuous rated (50 deg. C. rise) motors, for applications where the power requirements are definitely known.

Normal rated (40 deg. C. rise) general purpose motors.

Adjustable speed motors for continuous or intermittent service.

Generators and exciters.

For constant speed motors the ratings and speeds are the same as those of 60-cycle induction motors,

25-HP. MOTOR WITH GRID REMOVED

and they can thus be used interchangeably with induction motors for direct-connected applications without changing the method of drive or the ratio of gearing.

Adjustable speed motors, intended particularly for machine tool and similar applications, are provided for 2:1, 3:1 or 4:1 speed range. Generator speeds also correspond to those of induction motors, thus permitting the direct coupling of the machines to form motor-generator sets in various combinations.

The line of ratings now complete covers motors from $\frac{1}{2}$ to 50 hp. and generators from $\frac{1}{2}$ to 40 kw., while larger sizes are under development.

Cast steel yokes, combining light weight and rigid construction, are used for the larger ratings, while the smaller machines, which are of the bi-polar type, have riveted frames.

The accessibility of the commutator is apparent from the photographs. Protecting grid covers can be provided for these openings in the front bearing bracket; they are readily attached and may be applied even to machines in service, without affecting the rating. Solid covers are used with completely inclosed motors, the rating of these machines being somewhat lower than open or semi-inclosed motors.

All machines have ring-oiling, dust-proof bearings.

TYPE "E" MOTOR DISMANTLED, 25 HP., 230 V., 1150 R.P.M.

while the windings are treated to resist oil and moisture. Conduit terminal boxes, regularly supplied, have removable covers, giving ready access to the terminals. Box type brush holders are adjustable for tension and suitable for either direction of rotation. Each holder can be removed independently with a screwdriver.

The field coils are wound on metal spools, which prevent any movement of the coils, and are protected by an outside layer of enameled wire. The armature core has the laminations riveted together, permitting the removal of the shaft without dismantling the core or commutator, while with ratings of 20 hp., 850 r.p.m. and larger the core and commutator are built on a sleeve, so that the shaft can be pressed out of the finished armature without disturbing the windings.

An important feature of the machine is the very thorough ventilating system which has been provided, the air being drawn out by the fan mounted on the rear armature head; fresh cool air flows in through the liberal ventilating ducts and takes up the heat from the iron and windings. This heated air is forced out through openings in the periphery of the rear bearing bracket. With thorough ventilation the internal temperatures are kept low, thus greatly prolonging the life of the insulation.

Tin-Plate Manufacture in Japan

In Japan the demand for tin plate is continually increasing. The manufacture, however, cannot be pursued profitably in this country. Most of the imports come from America. In 1916 about 65,000 lb. were imported, but thereafter the annual shipments were reduced to 40,000 or 45,000 tons, owing to the war. Since the proclamation of the armistice imports have been showing a slight increase, but are not sufficient to satisfy the demand in this country. It is reported, according to the *Japan Chronicle*, that the Yawata State Steel-works in Kyushu have for some time past been carrying on experimental work in the manufacture of tin plate, and the results are so promising that commercial manufacture is soon to be started and the product put on the market.

Book Reviews

TIMBER; ITS STRENGTH, SEASONING, AND GRADING. By *Harold S. Betts*. 234 pages, 8 inserts of tables and maps, illus. New York: McGraw-Hill Book Co., Inc.

This book is intended for engineers, manufacturers and users of lumber and fills a long felt want for a comprehensive reference volume on wood construction in the engineering field. Coming as it does from the pen of a writer immersed in the many phases of timber research at the Forest Products Laboratory, the large amount of data presented bears the stamp of highest authenticity. The short introductory chapter on resources of the United States presents in a concise manner the source of timber supply as it exists today, clarifying a situation which to many has hitherto been rather vague. The chapters on structural properties of wood, effect of moisture and the strength of wooden products cover the field of wood construction. A wealth of usable information is given in exhaustive tables, together with methods of testing the strengths of various timbers. Detailed applications of species in telephone poles and cross-arms, vehicle manufacture, packing containers, and structural parts are entered into. Many engineers are cognizant of the fact that life is added to the structure by employing seasoned wood, but few realize that kiln-dried timber is really essential to economical construction. Large savings may be effected by care of the lumber pile in storage. These features, with all the refinements of operation, are given in a chapter on the seasoning of wood. The grading of lumber by the manufacturers' associations acquaints the reader with the vernacular of the industry, and the final pages on the national lumber production detail the commercial aspects. The book is well illustrated, the diagrams and tables are largely extracted from official government data, and the text is such as appeals to the professional engineer. It is a handbook for the engineer.

HANDBOOK OF CHEMISTRY AND PHYSICS. Compiled by *Charles D. Hodgman*. 554 pages, flexible pocket size, seventh edition, 1918. Cleveland, Ohio: The Chemical Rubber Co.

The author was assisted in the preparation of this book by Melville F. Coolbaugh and Cornelius E. Senseman. The latter contributed the chief features of this edition in the form of an enlarged table of physical constants of organic compounds, occupying over 100 pages and listing over 2000 compounds. Many of these substances which have only recently become important are listed together with the more common alkaloids and salts. The necessary properties are tabulated for each compound.

The work is intended as a portable reference volume for use in the laboratory and field, and aptly combines the physical and chemical data necessary for practical reference.

The general chemical tables, properties of matter, heat, hydrometric and barometric tables, sound, electricity and magnetism, light and miscellaneous physical tables include a wealth of detail sufficient for ordinary purposes without becoming an exhaustive library and are supplemented by the usual mathematical tables, measures and units usually found in the engineers' handbooks.

No space is wasted on educational explanations, the result being a concise handbook for chemists and chemical engineers. As compared with previous editions the present one exhibits a marked improvement. It is the history of engineering handbooks in general that several editions are required to eliminate errors. The authors are to be congratulated on the present development.

DIRECTORY OF THE CHEMICAL INDUSTRIES IN CANADA.

The Dominion Bureau of Statistics, Census of Industry Division, Canadian Government, Ottawa, Canada, has issued a Directory of the Chemical Industries of Canada, as of date Jan. 1, 1919, for general distribution. The statistics were prepared at the request of the Honorary Advisory Council for Scientific and Industrial Research. This directory represents the results of the first part of a survey which was undertaken (1) to provide a directory of Canadian chemical industries and their products for the use of the trade and (2) to assemble data regarding the raw materials used, the products and by-products manufactured, imports and exports and other information calculated to indicate not only the importance of the industry, and the progress which it has made during the war, but also possible new and profitable trade openings in industrial chemical lines.

The directory includes all concerns engaged in the production of chemicals either as main products or by-products and concerns in which any of the processes used are essentially dependent on chemical change. It is divided into (1) an alphabetical list of various concerns, with the address of head offices, branch factories, and list of products; and (2) an alphabetical list of Canadian chemical products, with list of manufacturers producing each. The introduction to the directory is an able review of the recent progress and present condition of these industries.

THE METALS OF THE RARE EARTHS, a Monograph. By James Frederick Spencer. x + 279 pages. London and New York: Longmans, Green & Co.

One of the main causes for the slow progress realized in the industry of the rare earths was the lack of a systematic compendium of the existing but widely scattered literature on the subject. The putting on the market of Dr. J. F. Spencer's work, "The Metals of the Rare Earths," will no doubt eliminate the above-mentioned cause, and bring to the attention of those who have at heart the development of new industries the importance and adaptability of the rare metals and their salts to the constantly increasing present-day industrial and pharmaceutical demands.

This timely book covers the subject in a very logical manner from the standpoints of discovery and general progress. The profusion of the chronological and bibliographical references covering the period from the first discovery by Gadolin of a new oxide (yttria), in a mineral found at Ytterby, 1794, up to June 30, 1918, will be of the greatest help to open the field for individual research, and will also account for its becoming the *vade mecum* in the rare earths industry.

The monograph is divided into 10 chapters dealing respectively with the history of the discovery of the rare earths, their occurrence, their separation, the method of controlling their fractionation, the Cerium group (cerium, lanthanum, praseodymium, neodymium, samarium), the Yttrium group (scandium, yttrium, europium, terbium, gadolinium, erbium, dysprosium, holmium, thulium, ytterbium, lutecium, celtium), thorium, their atomic determinations, their place in Mendeleeff's periodic system, and their uses.

Not enough praise can be given to the arduous task so well fulfilled to collect and co-ordinate the 1029 references

included in the book. The reference index and the indexes by authors and subjects are highly valuable adjuncts.

The assembly of the book leaves the impression that it is a useful addition to the English technical and scientific literature, and that it will find its direct use mainly in America, where the rare earths raw materials are relatively very abundant and their industry so very little developed.

J. S. NEGRU.

QUALITATIVE CHEMICAL ANALYSIS. (A laboratory guide.) By W. W. Scott, Research Chemist, General Chemical Co.; 350 pp., 15 cuts; third edition. New York: D. Van Nostrand.

This very excellent text is an extension of the previous editions and follows their policy of "furnishing a practical, up-to-date guide for students studying qualitative analysis." The book is admirably adapted to this end, but where the purpose of the course is to teach largely the principles of general chemistry and to use qualitative analysis as a vehicle, this text is perhaps not so well suited.

Of this third edition the author says: "The greater portion of the text has been rewritten and new material added, although the general plan of the original work has been retained. Under 'Laboratory Exercises' a large number of chemical equations have been introduced for the purpose of emphasizing the reactions. The lists of questions at the close of each group of elements have been enlarged. In Part V, tables of chemical compounds have been added. Part VI is entirely new. This includes the less common elements, which are important on account of their technical use. This section will be of value to those desiring an extended course in qualitative analysis."

The book is unusually well printed and indexed. These facts, coupled with the careful organization, make it a book that will be especially satisfactory to the student, whether used as a laboratory manual or as a reference.

SETH C. LANGDON.

INDUSTRIAL GOODWILL. By John R. Commons. 214 pages, illustrated. New York: McGraw-Hill Book Co., Inc.

Professor John R. Commons of the University of Wisconsin has written a condensed treatise on problems at issue between employers and employed, in a book called Industrial Goodwill, published by the McGraw-Hill Book Co. He is modern in his views, and sane withal, which has become an attribute of distinction in the discussion of the rights and wrongs of labor and capital. He considers labor as a commodity, and again as machinery, and concludes that the descriptions are inadequate. Under Goodwill he explains how fragile and indeed how intangible it is, and yet he demonstrates that it is that which converts the "class struggle" of socialism into class harmony. Chapters on The Public, Democracy and Solidarity, develop these concepts in their relation to labor, while that entitled Theory and Practice is a little homily on common sense with "Two and Two Are Four" as his text. He declares that principles are empty until they are filled with facts, and that two dogs and two cats do not of necessity make a complete, harmonious, and perfect body of four friends. In short, it is a plea for reasonableness. There follow chapters on Security, The Labor Market, Insurance, Health and The Shop. He explains why organized labor opposes local organizations of employees that become bound in interest to single employers, and who prefer to remain in security rather than to act in concert with others who are engaged in similar occupations. Nevertheless he holds that the advantages of collective life insurance, health insurance, services of physicians and nurses, and even those features of interest which avoid turnover in employment are desirable, and do contribute to the general welfare. Under Education he says he found in Pittsburgh that the minimum value of the English language was 2 cents an hour. An employer who engages immigrants at less than the full cost of American laborers should be required to send his employees to school during the daytime, at his own expense, is an opinion expressed. "That the immigrant should become American, and that his employer should give thought and money and leadership to bring him to an understanding and love of America

is but a small compensation for what America does for them." He tells of a corporation that started a school for apprentices. "After spending considerable money on their education, as soon as the apprentices reached a point where they could return something on the investment, and even before their education was completed, other employers began to steal them away by offering higher wages." The book is anti-socialistic, but it does not indicate that all employers are beautiful white angels, by any means. Under the head of Education he also brings out the theory that interest in the day's work does not depend on a remote expectation of reaching the top; it is rather the *next step* in advance that is of interest and encouragement to the workers.

Other chapters follow on Loyalty, Personality, Depression, and The World, the last being a thoughtful review of the doctrines of Karl Marx and their influence in various countries, together with some points that Marx missed in his manifesto. He brings out how, in this country, when the war came on, the Socialists and the Industrial Workers of the World promptly took sides with Marx in his theory of internationalism, and were willing to let Germany win, while the trade unions just as promptly took the side of America. Both had similar grievances, and similar aims. But the trade unions saved us. And he believes that there are spiritual forces at work, forces of solidarity, co-operation, and of partnership which can successfully appeal to goodwill rather than to contention and hate.

The book is not a compendium for factory organization, nor will it prove of interest to the employer who wants a formula for success. But to those who think, and who are endowed with the sometimes sorrowful illumination of character, the book is worth reading and helpful as well.

ELLWOOD HENDRICK.

Personal

Mr. G. A. BURRELL, formerly chief of the Research Division, Chemical Warfare Service, is now at 120 Broadway, New York City, as vice-president of Richmond Levering & Co., Inc., president of the Island Refining Corp., vice-president and general manager of the Raritan Refining Corporation, director and member of the executive committee of the Allied Oil Corporation, and director of research of the Richmond Levering-A. B. Leach interests, the Ohio Fuel Supply Co., and the Manufacturers Light & Heat Co.

Mr. W. J. COTTON, formerly with the Color Laboratory, Bureau of Chemistry, Washington, D. C., is now with the Research Division, National Aniline & Chemical Co., Buffalo, N. Y.

Mr. R. G. HALL, manager for the Burma Mines, has been in London, and is now returning to Burma.

Dr. HAROLD HIBBERT has been appointed assistant professor of chemistry in the post-graduate research department of organic chemistry, Yale University, New Haven, Conn.

Mr. G. A. KUHLE, for many years with the Bayer Co., has been appointed manager of the New York office of the United States Color & Chemical Co., 25 Howard Street.

Mr. G. H. LEE, formerly with the plant of the Tate Iron & Steel Co., Sakchi, India, and more recently with the London office of the Consolidated Steel Corporation, New York, will go to Calcutta as sales manager for the latter company.

Mr. H. W. PHILBROOK, formerly with the General Electric Co. of Schenectady, N. Y., has been appointed district manager of the Schutte & Koerting Co.'s New York office at 50 Church Street.

Mr. HOWARD R. REESE, formerly with the Standard Parts Co., Cleveland, and prior to that in the sales department of the Carnegie Steel Co., Pittsburgh, Pa., is now sales manager of the Universal Steel Co., Bridgeville, Pa., maker of alloy and tool steels.

Mr. P. A. ROELOFSEN, Commissioner of His Excellency the Governor General of the Netherlands East Indies and

head of the Government's bureau for water power and electricity, together with Mr. WALTER BLASER, is studying the electrochemical industries and inspecting the hydro-electric installations of the United States and Canada.

Mr. ROSS E. WILLIS is now connected with the Lakewood Engineering Co., Cleveland, Ohio. He was formerly with the Bethlehem Steel Co. and during the war was general field assistant for the Cleveland District Ordnance Office.

Obituary

Mr. JAMES LAUGHLIN, JR., a director and a member of the executive committee of the Jones & Laughlin Steel Co., Pittsburgh, Pa., died at his home in Zellwood, Oct. 19.

Mr. ROBERT R. LUCKIE, superintendent of the Ashland Iron & Mining Co., Ashland, Ky., died Sept. 26. He was a graduate of the University of Pennsylvania and entered the steel business 15 years ago as chemist. Afterward he started in the open-hearth department and worked up to superintendent, which position he held until his death.

Mr. CHARLES N. MCFARLAND, general manager, Jaxon Steel Products Division, General Motors Corp., died at Jackson, Mich., Nov. 1, following an operation for appendicitis.

Col. H. A. MARTING, president of the Marting Iron & Steel Co., Ironton, Ohio, died Sept. 27, after a long illness.

Mr. WILLIAM A. STANTON, vice-president of the General Refractories Co., New York, died Sept. 28, in London.

Current Market Reports

The Non-Ferrous Metal Market

New York, Dec. 8, 1919:—Copper is firm, with speculators eliminated and producers in control of the market. The tin market is quiet, with light demand and ample stocks. The tone of the lead market is improving under fairly brisk demand.

	Cents per Lb.

The Iron and Steel Market

The prolongation of the strike at the union bituminous coal mines has produced a high tension in the steel trade, as the majority of mills are near the end of their stock piles, and wholesale closings are likely within a fortnight if the coal mines do not resume work. The mills have received some coal since the strike started Nov. 1, particularly in the early weeks, but not a great deal, their operation being largely upon stocks. Three tin plate plants

have closed in the past week, tin mills being naturally in the vanguard in this matter, since the steel has to be heated six times in the process of manufacture.

Dec. 2 the Fuel Administration announced that production of beehive coke would be restricted 25 per cent, in order to release coal. Furnace coke had already been in urgent demand, as a scarcity was clearly in sight with coke production restricted by shortage of coal. Last June and July Connellsville furnace coke for prompt shipment sold at about \$4. When the strike was three weeks old it was selling for \$6, and the day before news came out of the restriction order it sold at \$8, while two days after it sold at \$10. The tonnages involved were very small.

With such great uncertainties prevailing as to production of steel in the next few weeks, the producers have further restricted their sales policies, but the market is not closed by any means. Business between producers and their regular customers is proceeding much as usual, since it is merely a matter of entering additional tonnages, to be shipped after present obligations are completed.

The United States Steel Corporation subsidiaries and such other steel-producing interests as adopted the policy of adhering to the March 21 schedule of prices and avoiding price advances are adhering rigidly to that policy and there is no indication that there will be any yielding in future in this matter. Expressions of opinion that the market will get out of control of the conservative interests, by tonnage demand overwhelming the mills, probably represent cases of the wish being father to the thought rather than the result of mature judgment. Many sales of steel products have been made at premium prices, but the total tonnage involved is not large, and in all cases the delivery involved is prompt or relatively early.

THE ADVANCE IN PIG IRON

Further advances in pig iron have occurred in the past week, No. 2X foundry being up \$1 at Philadelphia and \$2 at Buffalo, while in the valley market basic is up \$1 and bessemer \$2 and foundry at Birmingham is up \$1. Prices are now quotable as follows: Foundry iron, delivered Philadelphia, \$38.10; at furnace, Buffalo, \$38; Cleveland, \$33; Chicago, \$33; Birmingham, \$34. The valley market stands at \$33 for foundry and basic and \$35 for bessemer, small lots having brought higher figures.

A change in the complexion of the pig iron is noted, one that may foreshadow a complete termination of the buying movement that has been sending prices upward in such excited fashion in the past few weeks. The volume of inquiry is greatly reduced and consumers in general show signs of being fairly well covered for the next few months. The point with the consumer now is not to buy iron but to be assured of delivery of what has been bought. There is little anxiety to take deliveries for the balance of this month, on account of the influence upon inventories. It is developed that considerable tonnages of iron, particularly in the East, were bought speculatively, and some of this iron is now being offered for resale. One thing the furnaces have definitely accomplished by marking up pig iron prices has been to bring about higher prices for coke, and there is a possibility that the rise in pig iron may induce an advance in Lake Superior iron ore for the 1920 season. A month ago it was regarded as definitely settled that there would be no change in ore prices.

The Chemical Market

New York, December 5, 1919.

A settled market exhibiting little activity is the record of the week, with but slight change in prices and a continued fair demand. The imminent coal shortage of a few days ago that seriously threatened some lines of the trade at the present writing is beginning to look more hopeful.

GENERAL CHEMICALS

The market has been sluggish due to a lack of raw materials, demand being good but the available supply not sufficient to meet the requirements. *Sodium bichromate* jumped from 15c. to 18c. per lb. and *formaldehyde* is going at 32c. per lb., against 26c. last week. Inquiries have been

heavy on *sodium nitrite* at 14c. per lb. Since the Association fixed the price, *caustic soda* has remained firm at \$3.80 less 5 per cent per cwt. f.a.s. N. Y. *Sulphuric acid*, 60 deg. is quoted at \$23 per ton.

COAL-TAR PRODUCTS

General conditions point to another increase in prices throughout the list and this observation has been strengthened by a rumor going around the trade that the jump will come soon. Inquiries have been numerous on *alpha naphthylamine* at 35c. per lb., with very little to be had, while *paranitrotoluol*, at \$1.50 per lb., is practically off the market. *Aniline salts* is still rising, being quoted at 40c. per lb., with a jump in *dimethylaniline* to 67c., against the last quotation of 65c., while *saliicylic acid* is 55c. per lb., against 48c. in the previous report.

WAXES

Inquiries have been heavy in this market, with a slight scarcity of material the only hindrance to an otherwise very active market. *Beeswax, refined yellow*, is to be had at 44-47c. per lb., and *white pure* has fallen to 63-65c. *Candelilla* has been cut to 33c. per lb., and *carnauba*, No. 2 *North Country*, dropped to 46c. per lb., and No. 3 *North Country* to 46c. per lb., while *Japan* jumped to 21c. per lb.

Flotation oils have been dull, with pine oil, steam distilled, advanced to \$1.25 per gal., and crude turpentine to \$1.20 per bal., while hardwood oil, 0.960-0.990, f.o.b. Mich., is now selling at 35c. per gal.

Vegetable oils have been quiet; linseed oil raw is quoted at \$1.87 per gal., boiled \$1.89, and rapeseed oil (blown) jumped from \$1.70 to \$1.75 per gal., while peanut oil crude, f.o.b. South, is 2c. higher than last week, the present price being 23½c. lb. Exporting has been rather heavy in *naval stores*, with Japan a heavy buyer, especially in the medium grades. Rosin is quoted at \$17-\$17.65 per bbl. (280 lb.), while spirits of turpentine range from \$1.61-\$1.65 per gal.

The effects of the coal situation have probably been felt most acutely in the *crude rubber* trade, several tire plants having reduced output. The market is at a standstill with very little material available in any of the grades. A nominal quotation of 51½-53c. per lb. is given on crepe, and ribbed smoked is priced at 51½c., while fine para is going at 48½c.

Ferro-alloy prices in general remain unchanged, with continued brisk demand and a slight lagging of supply in some quarters. Inquiries, both foreign and domestic, are still heavy, with several establishments contracting into the new year.

The steady advance in the production of steel has caused a very heavy demand on ferromanganese, quoted at \$115 gross ton, with manganese ore receiving considerable attention. The arrival of 1000 tons of chrome ore from South Africa has not materially affected the market of this item, still quoted at 30c. per lb., chrome contained, while the use of molybdenite in place of vanadium in the manufacture of alloy steel has not changed the general condition, the old price of 75c. per lb. MoS₂ remaining. Exporting in wolframite has been dull, as Europe can get it by direct shipment from China, due to rate of exchange, at a price below our present quotation of \$7-88 per unit.

Feldspar remains lethargic. There is no material on hand and inquiries continue to pour in, while *barytes* remains firm at \$34-\$36 per ton with a sharp domestic demand. The uncertainty as to whether the Government will decide that petroleum coke is a fuel and fix the price with the attendant preference list, or allow the producer to continue making his own price has clouded matters in this field. The return of the miners to their work would undoubtedly settle this question.

The continued rise in *shellacs* is caused by a shortage of Calcutta crops, but with the advent of a new crop at hand it is hoped that the stringency will be relieved. TN has jumped to \$1.20 per lb., while orange fine and superfine continue to rise, the former quoted at \$1.35 per lb. and the latter at \$1.25. A.C. garnet and bleached, bone dry and fresh ground, have each increased 5c. a lb. The return of the Calcutta exchange to normal will entail a general rise.

Alpha naphthol, crude	lb.	\$1.00	\$1.10

Cassiterite, minimum 25% U ₃ O ₈ , per lb. of U ₃ O ₈	lb.	2.75	3.00
Zircon, washed, iron free.....	unit	21.00	..
Monazite, per unit of ThO ₂	unit	42.00	..

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags.....	bbl.	\$2.80	..
Lump lime, common, including container.....	300 bbl.	2.65	..
Common brick, at dock.....	M.	16.00	..
Yellow pine, 3 x 8, 20 ft. and under.....	M.	18.00	..
Yellow pine, 3 x 4 to 8 x 20 ft. and under at Chicago.....	M.	50.00	..
Yellow pine, 3 x 4 to 8 x 20 ft. and under at St. Louis.....	M.	40.00	..
Roofing, tar pitch (in 400-lb. bbl.) carlots.....	ton	70.00	..
Roofing, tar pitch (in 400-lb. bbl.) carlots.....	ton	21.00	..
Roofing, asphalt felt carlots.....	ton	34.00	..
Roofing, asphalt felt carlots.....	ton	63.00	..
Roofing, slate-surfaced, per roll of 108 sq.ft. carlots.....	..	2.25	..
Roofing, slate-finished, per roll of 108 sq.ft. carlots.....	..	1.75	..
Linseed oil, raw in barrels.....	gal.	1.75	..
Linseed oil, 5 gal. cans.....	gal.	1.90	..
Red lead, dry, 100 lb. keg.....	lb.	13.00	..
Red lead, oil, 100 lb. keg.....	lb.	14.00	..
Red lead, dry, 5 lb. cans.....	lb.	1.65	..
Red lead, in oil, 5 lb. cans.....	lb.	1.15	..
White lead, dry and in oil, 100 lb. keg.....	lb.	13.00	..
White lead, dry and in oil, 25 and 50 lb. kegs.....	lb.	6.00	..
White lead, dry and in oil, 5 lb. cans.....	lb.	.15	..

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45	..
Angles, 3 to 6-in, 1-in. thick.....	100 lb.	2.45	..
Tees, 3-in. and larger.....	100 lb.	2.45	..
Plates.....	100 lb.	2.60	..
Rivets, structural, 1-in. and larger.....	100 lb.	4.00	..
Rivets, conehead for boilers, 1-in. and larger.....	100 lb.	4.30	..
Sheets, No. 28 black.....	100 lb.	4.35	..
Sheets, No. 10 blue annealed.....	100 lb.	4.35	..
Sheets, No. 28 galvanized.....	100 lb.	5.70	..

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

NOTE—These Items were compiled as of Dec. 5, but appear in this issue due to the delay in publication due to the printers' strike.

District of Columbia

WASHINGTON—The Bureau of Standards will soon award the contract for furnishing material and constructing 3 chemical laboratory tables complete with superstructure, drain boards, and peg racks, and 2 of same without superstructure, drain boards and peg racks, and 10 maple top tables, 7 ft. long, 30 in. wide, and 12 in. thick.

Florida

MURDOCK—W. S. Wilson, Dothan, Ala., has purchased a large acreage of timber land near here, and plans to construct a turpentine distillery on same.

Iowa

WINFIELD—The city will receive bids early in January for the construction of sewers and a sewage disposal plant. Estimated cost, \$100,000. H. R. Green, 101 West 2nd St., Cedar Rapids, engineer.

Maryland

CURTIS RAY (Baltimore P.O.)—The Standard Wholesale Phosphate Co., 1214 Continental Bldg., has awarded the contract for the construction of a 1-story 60 x 216 x 320-ft. acid phosphate plant on Aspin St., to the Whiting-Turner Construction Co., Stewart Bldg., Baltimore. Estimated cost, \$72,000.

Michigan

DETROIT—The General Carbon Co., 542 5th Ave., New York City, has awarded the contract for the construction of a 1-story, 100 x 120 ft. manufacturing plant, a 1-story, 40 x 50 ft. boiler house and a 1-story, 25 x 30-ft. garage, to the Austin Co., 217 Broadway, New York City. Estimated cost, \$75,000.

North Dakota

WILLISTON—The city plans to install a new filter bed and make alterations in present waterworks plant. Miss Jack, city engineer.

Ohio

CLEVELAND—A. A. Chilcote Co. has purchased a site on East 21st St. and Superior Ave. and plans to construct a 2-story photographers commercial building on same. Estimated cost, \$100,000. A. A. Chilcote, 733 Prospect Ave., president.

CLEVELAND—The Middle States Rubber Co., recently incorporated, plans to construct a large factory for the manufacture of tires, tubes and other rubber articles in this vicinity. James L. Lind, Municipal Court, and E. Ewing, 3206 West 98th St., interested.

HIRAM—Hiram College plans a campaign to obtain funds to construct a 4-story men's dormitory and science building. Estimated cost, \$600,000. F. A. Hoyer, 405 Sloan Bldg., Cleveland, manager in charge. Abram Garfield, National City Bank Bldg., Cleveland, engineer.

Oklahoma

OKLAHOMA CITY—The State Board of Health has ordered the city to install a sewage disposal plant. Estimated cost, \$1,000,000.

New Jersey

JERSEY CITY—The city will soon award the contract for the furnishing and delivery of hypochlorite of lime and liquid chlorine for a period of 12 months for the treatment of Jersey City water supply at Bonton.

Texas

PLAINVIEW—The City Council will soon award the contract for the construction of a sewage treatment plant consisting of Imhoff tank and sprinkling filters, filter material, etc. J. F. Frye, secretary.

Washington

SEATTLE—F. A. Narramore, architect, Central Bldg., will soon receive bids for the construction of a 3-story, 250 x 250-ft. factory on 8th and Dexter Sts., for the manufacture of school furniture, laboratory equipment, etc. for the School Board. Estimated cost, \$160,000.

Wisconsin

MADISON—The Madison Klipp Lubricating Co., Waubesa St., has awarded the contract for the construction of a 52 x 240-ft. addition to its present shop, to George C. Coare & Son, 3000 Jenifer St. Estimated cost, \$200,000.

British Columbia

SQUAMISH—H. Hudson, Everett, Wash., is conducting preliminary negotiations with a view to constructing a pulp mill at the terminus of the Pacific Great Eastern Railway, near here, for the American Syndicate. Estimated cost, \$1,000,000. John Callaghan, Vancouver, engineer.

Ontario

POSTON CREEK—The Miller Independent Mines, Ltd., plans to construct a 100-ton mill, also install a new electrical plant, in connection with its gold mine here. C. A. Miller, superintendent.

FORT CREDIT—The St. Laurence Starch Co. has awarded the contract for the construction of a 4-story, 60 x 150-ft. building, to Wells & Gray, Confederation Life Bldg., Toronto. Estimated cost, \$30,000.

Industrial Notes

THE FOUNDATION OVEN CORPORATION is a new concern specializing in the "American" coke-oven, lignite-oven, carbonization process, recovery system, and coal products refining system. Its literature announces a complete chemical engineering service from test tube to finished plant. This is made possible through the association of the Foundation Oven Corp. with the Foundation Co. and the Foundation Research Laboratories, Inc. F. E. Brothart, lately major in the Chemical Warfare Service, is associated with the Foundation Oven Corp. with headquarters in the Woolworth Bldg., New York City.

THE METALS PRODUCTION CO., Chicopee, Mass., will pay creditors a first dividend of 10 per cent on all claims which have been approved and allowed and are not entitled to priority. The trustee has been ordered to pay in full all claims which have been approved and allowed and are entitled to priority. The dividend is payable immediately by Trustee Harry C. Dodge, Boston, Mass.

THE GARRED-CAVERS CORP. has made contracts and issued licenses for the use of the Garred-Cavers process at the smelters of the following companies: The International Nickel Co. of Canada, Ltd., the Tennessee Copper Co. and the Cerro de Pasco Copper Corp.

THE DRIVER-HARRIS CO., Harrison, N. J., is now selling its wire rope products direct to the trade instead of through its former selling agents. These products include ash cord and tiller rope in plain iron, galvanized iron, phosphor bronze, special bronze, monel metal, and all special grades. In addition to this, the company has increased its facilities to include all grades of rope in 6 x 7, 6 x 12, and 6 x 19 construction, monel metal, and all special grades. It also handles rope, sand lines, etc. in all sizes up to 3 in. The other products of the company are resistance materials of nickel alloys in

the form of wire, strip and sheet for electric heating, control coils, rheostats and resistance elements, wire for spark plugs and weaving, rods and sheets of pure nickel and its alloys, cold rolled strip steel; nichrome castings such as annealing boxes, carburizing boxes, pots, tubes, rotary and stationary reactors, dipping baskets, pyrometer protection tubes, etc.; flexible heater cord and thermistor.

THE ELECTRIC FURNACE CO., ALBANY, Ohio, recently shipped to the Dayton Engineering Laboratories, Dayton, Ohio, an electric furnace for melting and redning aluminum in the Deleo plant. This furnace has a hearth capacity of 500 lb. and a melting rate of 200 lb. of aluminum per hr. It is equipped with a double charging door in the front and rear, and otherwise is similar to the standard highly electric furnace of 105-kw. electrical capacity, and 1500-lb. hearth capacity, that is used for melting brass.

THE INGENSOLL-LAND CO., ALBANY, Ohio, has established a branch office at Sam Houston Life Bldg., Dallas, Texas, the better to serve the Texas and Oklahoma territory. The office will be in charge of Mr. R. L. Brown, Jr.

THE BOOTH-HALL ELECTRIC FURNACE CO. was organized in Chicago during the latter part of September with a paid-up capital of \$1,000,000, one-half preferred stock and one-half common. This company was formed to take over all the assets and goodwill of the Booth-Hall Co., manufacturer of electric steel and brass melting furnaces. The new company has also taken over the business of the former company and proposes to develop the electric furnace business along standard manufacturing lines. It is now prepared to deliver furnaces in sizes, 500-lb., 1000-lb., 1500-lb., 2000-lb., equipments. The two-phase two-electrode Booth-Hall furnace will be made in five sizes, i.e., 1-ton, 1½-ton, 3-ton, 6-ton and 12-ton, and an improved type of furnace is also being designed. Associated in the management of the company will be a number of engineering and operating executives in the public service, including E. Myers, of Chicago, president of the L. E. Myers Co., has been elected president of the new corporation; Mr. C. H. Booth, formerly president of the Booth-Hall Co., vice-president; Mr. W. K. Booth, formerly chief engineer of the Booth-Hall Co., secretary; and Mr. L. J. Clark, of the L. E. Myers Co., treasurer. In addition to the president, vice-president, secretary and the board of directors will include Mr. Martin J. Insull, vice-president of the Middle West Utilities Co., and Mr. E. W. Lloyd, of the Commonwealth Edison Co., both of Chicago.

THE CARBORUNDUM COMPANY announces the opening of branch offices and warehouse in Detroit, Mich., in the Burkhardt Bldg., at Second St. and Leland St., under the direction of Mr. Anthony Dobson, who will have charge of the Detroit sales district. The new offices and the warehouse have been opened with the view of giving better service to the users of carborundum products in the Detroit district, and to that end a complete stock of carborundum and aloxide grinding wheels, carborundum and aloxide paper and cloth and other carborundum products will be carried.

THE ST. LOUIS COKE & CHEMICAL CO. has disposed of \$5,000,000 of 8 per cent cumulative preferred stock to the Studebaker Bros. Trust Co. of Chicago and the Mississippi Valley Trust Co. of St. Louis. The proceeds of the sale will be used for the construction of a new coke-oven and hot-blast-furnace plant now being erected at Granite City, Ill. The entire output of hot metal, gas and tar has been contracted for a period of years to the National Enameling & Stamping Co.

HUNTINGTON, HENRELEIN & CO., LTD., announces that the entire capital stock of the corporation has been acquired by Messrs. Henry Gardner & Co., Ltd., and that the business offices of the former will be transferred to the registered offices of the latter at 2, Metal Exchange Buildings, London, E. C. 3. The board of Huntington, Hiberfeld & Co., Ltd., London, consists of Henry Gardner, chairman and managing director; H. C. Bingham, H. J. Bush and R. H. Bingham.

THE ARMSTRONG BUREAU OF RELATED INDUSTRIES, 11 South LaSalle St., Chicago, is a new institution the first of its kind, founded on the principles that American business can reach its highest development and perform its greatest service to the commonwealth only through modern, co-operative methods. It renders a professional service by which competitive businesses attain a maximum of efficiency in operation. In organization, marketing and production. Mr. John Walsh, acting and chief counsel for the Federal Trade

Commission from its inception to April, 1918, has identified himself with this organization and will furnish his exclusive services to it on all matters pertaining to business and industrial co-operation. Mr. Walsh maintains headquarters in Washington, D. C.

M. FERRARIS & Co., agents of the American Steel Export Co. for Italy, state that the continued activity and development of Italy as a field for American machinery, equipment, steel and metal products have caused them to send Mr. Joel B. Ives of the engineering and contracting department of the Export Company to Italy to confer with the Italian agencies as to methods of dealing adequately with the situation and insuring the continuance of effective sales service in that territory.

THE STANDARD CHEMICAL CO. of Toronto, the stock of which is largely held in England, has elected to the presidency David Gilmore, an eminent Scottish engineer of wide experience.

THE ELECTRIC FURNACE CONSTRUCTION CO., Philadelphia, Pa., addresses orders received for Grease-Etchals electric burners from Lacheze et Fils, Dijon; and C. Markham & Co., Ltd., Chesterfield.

THE WESTINGHOUSE ELECTRIC & MFG. CO. has announced the award of its four annual War Memorial Scholarships of \$500 each. The following are the men who received the awards, the courses chosen and the schools at which their studies will be conducted: Elmer E. Cline, Cincinnati, Ohio, technical engineering course at the Univ. of Wisconsin; Arthur Martens of East Pittsburgh, Pa., electrical engineering at the Carnegie Institute of Technology; Paul O. Languth, East Pittsburgh, electrical engineering at the University of Pittsburgh; Andrew P. Lesniak, East Pittsburgh, electrical engineering at the University of Pittsburgh. Each scholarship carries with it an annual payment of \$500 for a period not to exceed four years. The payment will be applied toward an engineering education in any technical school of college selected by the successful candidate with the approval of the scholarship committee. Three scholarships have been established as a memorial to those employees of the company and its subsidiaries who entered the service of their country during the war. Four awards will be made each year so that after three years this company will be maintaining sixteen of these scholarships in the best technical schools of the United States.

THE CHICAGO PNEUMATIC TOOL CO. announces that on Oct. 1 its Birmingham office was removed from 801 Brown Marx Bldg., to 1925 Fifth Ave. North, where a service station with a complete stock of pneumatic tools, electric drills, compressors, oil engines, rock drills and repair parts is maintained. This company also announces that Mr. C. W. Cross has been appointed manager of Western railroad sales with headquarters at the Fisher Bldg., Chicago.

Manufacturers' Catalogs

THE SCHUTTE & KOERTING CO., Philadelphia, desires to announce that it has issued a revised 8-B catalog on Stop, Stop Check and Order. Free and will be pleased to forward a copy to those interested and inquiring for same.

THE GOULDS MFG. CO., Seneca Falls, N. Y., has published a bulletin entitled "Centrifugals for Service in the Chemical Industry." This bulletin is a series of sales letters for its own organization, but owing to the demand from outside sources, the company has decided to publish them in bulletin form and will be glad to send one on request. The bulletin contains information on theory, designs, testing, etc., of centrifugal pumps.

THE BARBER-GREENE CO., Aurora, Ill., announces a new catalog showing the latest B-G standardized material handling machines, standardized belt conveyor (portable and stationary) and standard bucket loaders. Copies will be sent upon request.

THE TOLHURST MACHINE WORKS, Troy, N. Y.; Catalog 8 is a new and attractive catalog on its centrifugals (hydro-extractors), which are illustrated and described.

THE CURTIS & CUMMINS MFG. CO., Chicago, Ill., calls attention to Bull. No. 141 on steam jacketed pumps and steam jacketed pipe fittings.

THE CLEVELAND INSTRUMENT CO., Cleveland, Ohio; "Cleveland Resistance Pyrometers" is the title of Bull. No. 40, just issued.

THE KOPPERS COMPANY, Pittsburgh, Pa., has issued attractive 68-page catalog illustrating and describing by-product coke and gas plants, benzol recovery plants, motor fuel recovery plants, tar distilling plants and ammonia recovery apparatus.

THE QUICKLEY FURNACE SPECIALTIES CO., New York City; "Carbosand" is the title of a new booklet, just issued, describing a refractory granular material for rammed-in linings, special tile patches and repairs in furnace structures. Another booklet is "Hytemite in the Foundry," which describes the use of the high temperature cement in the various phases of foundry practice, taking up in sequence its applications in the iron foundry, steel foundry, brass foundry and malleable foundry.

THE LEA-COURTENAY CO., Newark, N. J., has recently issued two new bulletins: One, termed No. 4, is a veritable treatise on centrifugal pumps as well as catalog of its most complete line; the other, Bull. S-5, gives a synopsis of typical centrifugal pumps included in various industries, showing the range of pump services and the centrifugal pumps cover. Copies will be sent upon application.

THE MILLIKEN BROS. MFG. CO., INC., New York City, is distributing catalogs of No. 10 and No. 11, descriptive of Milliken buildings. "Choice of a Thousand Buildings" is the title of Catalog No. 10, which illustrates and describes its buildings constructed by standardized truss unit system, designed to facilitate erection by rail or water or on animal back; to minimize the use of labor and tools in construction; and to meet a wide range of industrial needs. Catalog No. 11, "Erection Handbook," is a supplement to Catalog No. 10, and illustrates and describes in detail the necessary to make the proper foundations, and to erect any type of building selected, so that construction can be started just as soon as the material is received.

THE NEW JERSEY ZINC CO., New York; Five new booklets have been issued by this company, entitled "Chemicals," "Roller Zinc," "Zinc Dust," "Pigments" and "Metals."

THE METAL & THERMIT CORP., New York City, has issued a folder entitled "How Thermit Cured My Diseased Neck," which illustrates a thermit welding repair, consisting of building up with thermit steel the worn pods on the end of a 18-in. dia. neck of a large roughing mill pinion.

THE W. S. ROCKWELL CO., New York, will gladly send to anyone interested its new steel heat-treatment chart.

THE BAILEY METER CO. is distributing Bull. No. 30, entitled "Fluid Meters for Low-Pressure Gas and Air."

THE ELECTRIC FURNACE CO., Alliance, Ohio, calls attention to three new booklets, just received from the printer. Booklet 7-B deals with electric furnaces for melting iron; Booklet 17-B describes a special furnace for rolling mills which is designed for pouring the metal directly into the molds; Booklet 13-B is a discussion of the various electric non-ferrous metal melting furnaces, which is a reprint of the paper delivered by T. F. Baily before the American Institute of Chemical Engineering, Boston, Mass., at the June, 1919, meeting.

SARCO COMPANY, INC., New York City; "Steam Trap Sarco" is the title of a new four-page booklet just issued.

THE STAR BRASS WORKS, Chicago, Ill., has just issued a 24-page bulletin, No. 5, covering atomizing spray nozzles and special applications. This literature deals with the application of spray nozzles for all industrial purposes, also engineering data involved in same. Copies will be sent upon request.

THE COMBUSTION ENGINEERING CORPORATION, New York City, calls attention to its latest catalog on Grive Grates, which illustrates and describes the design and operation of the grate. This attractive catalog will be sent upon request to anyone interested in burning a wide range of fuels under the best conditions, with a high degree of economy.

THE BICYCLE MANUFACTURERS' ASSOCIATION, Hartford, Conn., has published a booklet entitled "Industrial Transportation." This booklet calls attention to industrial concerns as to the advantage of a bicycle as a method of transportation for its employees.

THE PETROLEUM IRON WORKS CO., Sharon, Pa., has issued a catalog of steel bar stock, tie rods, tie bolts, tie plates, etc., illustrates and describes in 28 pages the

economic value of steel shipping containers, the "G-B-M" bilged steel barrels, the barrel with the hoop formation; "Prestel" C. C. drums, "Prestel" light gauge ship-light drums, and "P. I. W." storage tanks together with authoritative information relative to its manufacture, advantages, uses and general specifications.

THE WILLMAN-SLEAVER-MORGAN CO. desires to announce Bull. No. 27, which describes the automatic ore unloaders on the Great Lakes. Copies will be sent upon request.

THE FOXBORO CO., INC., Foxboro, Mass.; Bull. No. 194-1, entitled "Thermometers," is a complete treatise on the subject of temperature measuring instruments, which states that any temperature between the range of minus 60 to 1000 deg. F. can be measured accurately by these instruments. Special attention is called to pages 62 to 68, which show indicating thermometers with a clean draped style of dial, laid out from a scientific viewpoint to obtain the maximum visibility, and can be read without difficulty as far as 15 to 20 ft. Copies will gladly be sent upon request.

THE TELZIT SLIDE RULE CO., Chicago, Ill., has issued a booklet on the "Telzit" slide rule for instantly determining in advance the exact dimensions of a drawing or for use in drawing of layout enlargement.

BOWSER & Co., Fort Wayne, Ind., has issued a little folder which illustrates and describes a Bowser battery storage system for lubricating oil. The folder can be arranged to show one outfit, two outfits, three outfits or a battery of four tanks so that the prospective user may understand that he can buy as many units as he requires, and the folder shows him how the units of many various capacities line up in uniform manner.

THE OLIVER CONTINUOUS FILTER CO., San Francisco, Calif., has issued Bull. No. 12 describing the construction of Oliver's filter. The Oliver continuous filter and accessories. Illustrations showing apparatus under construction, in transit, and in actual plant operation are included, with information on the various sizes manufactured, the diversified products handled on the Oliver, and approximate capacities based on plant operations. The Oliver filter is fully covered, and the various adaptations of filter cloth, washing arrangements, etc., are completely explained. The Oliver sand filter, for handling coarse and fast-settling materials, is also described and illustrated. Copies may be obtained upon application.

THE WESTINGHOUSE ELECTRIC & MFG. CO., East Pittsburgh, Pa.; Bull. No. 1563, "Railway Converter Substations," is a compilation of ideas of operating engineers' experience in substation work, and data in connection with the Westinghouse standards and practices adopted after years of experience.

THE AMERICAN ORE RECLAMATION CO., New York City, has issued a booklet on "Sintering and Desulphurizing of Iron Ore Materials."

THE BLAW-KNOX CO., Pittsburgh, Pa.; Bull. No. 202, covering Knox water-cooled appliances for glass furnaces; Bull. 200, entitled "Blaw Cableways"; Bull. No. 233, "Blawform for Lignite Walls and Roofs"; "The Blaw System for Building Construction" is the title of Catalog No. 18. Any or all of these publications will be sent upon request.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis.; C-H space heaters are illustrated and described in a new 4-page pamphlet, No. 479, entitled "Miscellaneous Applications of Space Heaters." "Angular Magnets" is the title of Booklet J, which illustrates and describes various types of apparatus; "C-H Drum Control-Change" is the title of new "C-H" folder on this subject; C-H mine duty apparatus is illustrated and described in a new 8-page booklet which makes special reference to the mine duty apparatus installed in the plant of the St. Louis Smelting & Refining Co., St. Francois, Mo.

THE ALLIS-CHALMERS MFG. CO., Milwaukee, Wis.; A booklet entitled "Prospectus of Apprenticeship System," which shows a young boy who shows talent along mechanical lines, offers an opportunity for him to become a first-class mechanic; Bull. No. 1432-C, on "Allis-Chalmers System"; "Allis-Chalmers Prospecting Mill for Free Gold Ores"; Bull. 1456, "Fairmont Type Crusher"; Bull. 1537, "Details of Allis-Chalmers No. 10 Discharge"; "Allis-Chalmers ordering repairs and spare parts"; "Centrifugal Pumps and Centrifugal Pumping Units" is the title of Bull. 1632-C, which illustrates large- and small-size centrifugal pumping units.

Volume 21

New York, November 26—December 3, 1919

Number 13

Approaching Normal Publication Dates

LOOKING back through the pile of letters of encouragement which arrived during the time when publication of CHEMICAL & METALLURGICAL ENGINEERING was suspended certainly impresses us with the idea that the thinking public is sick and tired of strikes to extinction, and has little sympathy indeed for the bludgeoning attitude lately so much in evidence. As an instance:

Not that you need, but that it may aid in sustaining your moral position, I, a subscriber, state I am in sympathy with your action.

You are justified in any reasonable expedient to meet the conditions imposed upon you, and would be sustained by men like me if you asked extra financial support (if you are overtaxed) or a reduction in service pending the solution of this dilemma.

Unfortunately it was physically impossible with the whole local industry paralyzed to continue the service as we wished and worked for; however, we feel we are getting rapidly out in the open. Double editorial sections will correctly complete the volumes without an undue tax on either subscriber or advertiser. Complying with postal regulations is rather a difficult task, but even a casual reader can see that these issues are timely in all respects except the date line.

Importance of Data

On Small Volume Changes

ALTHOUGH numerous investigators have been making measurements of thermal expansion ever since LAVOISIER and LAPLACE began fairly accurate work of this character more than 135 years ago, the field to be covered has been scratched only at a few points. For instance, the total data on linear and cubic expansion of solids recorded in the 1916 edition of the Smithsonian Physical Tables occupy only two and one-half octavo pages, and most of the values given are derived from measurements of great antiquity. In the elaborate collection of physical constants issued by the French Physical Society in 1913, LE CHATELIER begins the section devoted to metallic alloys with the statement: "It is impossible to find numerical information concerning the physical properties of alloys which is worthy of any confidence."

A detailed description of A. W. GRAY's very convenient dilatometer should therefore serve to impress many experimentors with the fact that it is comparatively easy to determine such missing but important data with great precision. Its many applications to the field of structural engineering and machine design do not need to be enlarged upon.

For pure metallurgical research, however, the method is worthy of careful consideration. Thus, dimensional

changes during transition can be made the basis of a dilatometric method of thermal analysis which may reveal important new information. A knowledge of the magnitude of these changes is of particular importance when the materials have to be carried through such a region in the course either of their manufacture or of their ordinary use. Such knowledge would, for example, aid in determining the safe rate for heating or cooling large metal ingots.

The dilatometer can be made to throw light upon structural changes which take place at constant temperatures. As an instance, season cracking in bronzes, which has caused so much trouble in the water-supply equipment of New York City and in other cases, appears to be due in part to the action of differential expansions starting minute cracks which are greatly increased by the combined action of dimensional changes and corrosion.

More About American Dyes

PROTECTION against insidious German competition in dyes and allied chemicals is again urged by the President in his message to Congress, just convened. Quoting from his last message urging such legislation, he says:

"Among the industries to which special consideration should be given is that of the manufacture of dyestuffs and related chemicals. Our complete dependence upon German supplies before the war made the interruption of trade a cause of exceptional economic disturbance. The close relation between the manufacturer of dyestuffs, on the one hand, and of explosives and poisonous gases on the other, moreover, has given the industry an exceptional significance and value.

"Although the United States will gladly and unhesitatingly join in the program of international disarmament it will, nevertheless, be a policy of obvious prudence to make certain of the successful maintenance of many strong and well-equipped chemical plants. The German chemical industry, with which we will be brought into competition, was and may well be again a thoroughly knit monopoly capable of exercising a competition of a peculiarly insidious and dangerous kind."

But we fear the public as well as the Congressional mind has become rather confused by the many extraneous factors which have been introduced into the discussion. It is not a problem of foreign exchange, nor yet of the welfare of the men who have engaged in the manufacture of dyes in this country. The real problem is that of a vast German trust against what is still an infant industry. They can still make four times as many dyes in Germany as are made here. And they are going to make Americans sweat for what

they sell. The German choice in the matter would be to make the American makers of dyes suffer, rather than the users. They want this market, more particularly because other countries have either adopted the license system, and thus closed the Germans out, or they are in the process of doing so. Each nation wants national independence in dyes.

Now the merit of national independence in dyes is that it provides for an academic army of chemists organized to work in the organic field, and prepared to make explosives, gases, and the many unexpected products needed in war. If we want such a body of men for the same reasons that England, France, Italy and Japan do, we must have the industry. We cannot have the men without the industry.

It is not a controversial subject between textile men and chemical manufacturers. Whatever happens, textile manufacturers will have to pay, and pay well, for their dyes. It is only a matter of time whether we let the German products in or keep them out. If we let them in they will be cheaper only until the American industry is extinguished, after which, of course, the Germans will be able to charge their own prices. The real question involved is not whether one industry or another makes more or less profit, or whether the American dye manufacturers incur heavy losses. The question is, Do we want the comprehensive preparation for war that can be obtained only by the active support of the dye chemist? If we do, there is but one way, and that is to exclude imports by a license system. A higher tariff alone will not do it.

A Thought on Labor's Goal

AT ONE of the critical periods of the war the British Minister of Education, ALFRED HENDERSON, who was also general secretary of the Labor Party, became convinced that the way to achieve peace was by negotiation with the German authorities. As this was not in accord with the policy of the Allies, his resignation as a member of the Cabinet was accepted. While to the British Government the change in personnel involved in his retirement was but an incident in the day's work, HENDERSON took it as a personal affront. He held that he was persecuted for his honest convictions, and he made his appeal to Labor for peace by negotiation while the Germans still occupied Belgium and northern France. So strong was this argument in regard to the invulnerability of the Hindenburg line and the uselessness of continued struggle that Labor was disposed to follow him, and the production of munitions in England straightway fell off in increasing ratio. To offset this a number of American labor leaders were invited to visit England and other allied countries, to carry to the workers of those lands the doctrine held in America by both capital and labor—that the only way to end the war was to win it. The mission was successful.

The following conversation has been reported to us, between one of the American leaders and a French professor of law at the Sorbonne whose philosophy of politics is of a socialistic turn:

"What," asked the professor of the American, "is the goal of organized labor in your country?"

"I do not know," was the reply.

"Then you are bound to fail. You cannot make progress if you do not know what you want."

"Possibly," conceded the American, "but I cannot reach the conclusion that we should do better with a specific program. We have in our country a very able instrument called the Constitution. It was drawn by a body of men of consummate ability and lofty character. Speaking for myself and my associates in the organization of labor in the United States, we are not to be compared with them in ability or vision. But not one of those men had ever seen a railway, or a steamboat, or a line of telegraph wire. News and goods were carried by the wind at sea, and by horses and mules on land. Machinery of the modern type and industrial life as we know it today were undreamed of by them. Therefore it occasionally happens that important and needed legislation is forbidden by the letter of some article of the Constitution that was designed for entirely different conditions. Then the pundits of the law are driven to the most remarkable talmudic twistings of the Constitution to make necessary legislation possible. Sometimes they cannot do this, and then long delays involving injustice and suffering ensue.

"Now, we have ideals of physical welfare and of intellectual standards that we hope to see labor realize, but these are neither definite nor fixed. We feel that we do not know enough to legislate for the men and women who will toil fifty or a hundred years from now. We push ahead where we can, and sometimes we make mistakes. Sometimes mistakes are made, in spite of our efforts to prevent them. But we do not want to make our errors permanent. It seems better, on the whole, to trust to the future, and to the intelligence of those who are to come after us, rather than to guess blindly, and to run the risk of guessing wrong."

We should like to hear more of such talk, and hope the time may soon be at hand when this quality of frankness will be the habit in general discussion. There is not sufficient confidence to warrant it yet, and we believe there are too many undeveloped and immature minds engaged in the councils of labor to permit to their leaders that freedom of speech that wholesome discussion demands. The same may be said of many groups of employers of labor. They have "put over" too many tricks in the past to have won the confidence of their employees.

There isn't any egg-of-Columbus solution to the labor situation. It must be based on confidence, and there isn't enough of it. Traditions are bad on both sides. In the big shake-up that the world has undergone a great deal has come up from the bottom that is far from admirable. There are many loud voices heard with neither character nor understanding back of them. Now, character is essential. The German Government got along for many years without it and seemed to prosper, but it didn't last. Character is social protein, and we must have it if we would endure. A great many labor unions have not yet learned that an agreement is an obligation, and it will be a long time before some of them do learn it. They will have to be made up of a more intelligent membership, a membership than can figure on consequences, before this can be expected. But collective bargaining by men of character and intelligence will come about if we have a great deal of faith and patience in spite of many disappointments. With the present growth of a sense of obligation among employers we believe it will soon spread among employees; and when that comes about we may look for sudden rises in efficiency curves.

Steel Prices And Service

ONE may regard it as simply an incident following the war-time control of steel prices that there has been so little fluctuation in the steel market in the past twelvemonth, but there is probably a permanent influence at work, one that makes "service" count in the competition. There must be competition of one description or another. It was competition made the American Navy what it is, competition between men, gunner's crews and vessels. There is some competition that is not advantageous. When railroads were debarred from cutting passenger rates they indulged in wasteful competition as to the convenience of service, whereby many railroads lost money on their passenger service and operated more trains than were needed to accommodate the public.

Competition in steel service may be popularly described as "all to the good." Fitting the steel to the particular employment intended by the customer makes for progress, as consumption is encouraged, and the seller, having found a steel that meets the requirement of a certain consumer, is in position to offer the same class of steel to another consumer who he knows has the same problem.

Service in steel means much more than furnishing steel of the particular character desired. It involves regular delivery as well, and not only regular delivery, but ability to modify specifications that are on file and to transpose the order in which specifications are to be filled. As a practical matter ability on the part of the mill to render delivery service to the customer depends upon system. The better the system of handling orders the more readily modifications can be made.

By no means, however, does the whole matter rest with the manner in which orders or specifications are handled after they are received. The work starts with the sales department, whose duties formerly were regarded as being confined to selling as much tonnage as possible and at as high prices as possible. Now the duties and responsibilities of the sales department are much broader. It must pick the best customers, those whose orders will prove most profitable, price and actual cost of production being considered. It must endeavor to sell tonnages that will stay sold and to customers whose trade can be counted upon year after year. The sales department and the operating department work more and more closely together.

The railroad furnishing the best passenger service may make the least money. The steel mill furnishing the best service should make the most money, for the rendering of good service is the result of system and efficiency, which are always certain to pay. Opportunity for competition or rivalry being afforded, there is less occasion for price competition, hence market prices have less disposition to fluctuate.

Service means holding customers, hence an intimate relation between producer and consumer is built up and the producer has not the former incentive to encourage buyers to place orders farther and farther ahead. Some of the great buying movements of the past in the steel market were produced by tactics directly calculated to induce buyers to place contracts for another quarter or half year, and then for still another period. The later policy is to sell only a reasonable distance ahead and to take regular customers on for another delivery period when the proper time arrives. Accordingly the sales de-

partment is not bent upon selling the mill up for greater and greater distances ahead, but upon making sales commitments with which the subsequent orders or specifications will closely harmonize. The salesman is helping to run the mill efficiently instead of gathering up orders promiscuously and letting the mill take its chances in filling them.

Imagination And Success

COLONEL JOHN J. CARTY of the American Telephone & Telegraph Co. has honorary degrees from universities and decorations from Governments and emperors and kings enough to satisfy almost anyone. Lately, however, he has received two more: the Distinguished Service Medal of the United States, and Commandant of the Legion of Honor of France. His achievements in establishing communications at the battlefield and elsewhere during the war have already been discussed and acknowledged, and the present official recognitions are abundantly warranted.

We recall after the war with Spain a little script that had an enormous circulation, called "A Message to Garcia." It told of a Navy Lieutenant who had a message to deliver, and he delivered it. This called for energy and perseverance and pluck and all the virtues which we may safely include in our advice to young men who are making a good start. CARTY's task was different; it called for a measure of invention that is beyond most of us, as well as the inspiration of a great force of men and women to pull together, to work and to endure with patience and with all their minds and hearts until the dawn of victory.

Once upon a time when the telephone company was in its beginning he was only one of a number of men working with their wires, until it was observed that he used his head outside of business hours. Then when the problems of the day seemed insoluble it was CARTY who had been thinking over what might happen and who had a solution ready. He had the knack of calling upon his own intellectual reserves and making them work. Others might have done it, perhaps, but he was the one who did, and so they made him chief electrician—because they had to call him something that indicated authority. That was the start, and those marvelous reserves of his have been functioning in applied science unto this day. In telephony he is usually the last word in the art, and he is not an old man yet, by any means. Of course his native gifts were unusual, and but few of us have such endowments of imagination coupled with precise and mathematical thinking.

We refuse to practice hypocrisy, and to tell any boy who works for the telephone company that he may follow in the footsteps of Dr. CARTY. The chances are against it. But while no two of us are alike we have, or the most of us have, the gift of imagination, and in the work to which we refer we find his imagination constantly in function.

In taking a cue from his career if we were to offer advice to young men we should restrict ourselves to those who have the gift of wondering about things. Then we should urge upon them to take this gift along with them into daily life and after a while to see what dreams come true. If it seems straining a point to say that the sound of the harp that once through Tara's halls its soul of music shed may accompany higher mathematics and physics—here's the evidence of it.

Readers' Views and Comments

Contributions by Metallography to L'Art Nouveau

To the Editor of Chemical & Metallurgical Engineering

SIR: Those who saw the Post-Impressionist Exhibition of paintings and sculpture held in New York shortly before the war will recall that one of the most engaging canvases bore the title, "Nude Descending a Staircase," that it might have hung with propriety in

FIG. 1. AJAX DEFYING THE LIGHTNING
Brass (Cu 67, Zn 33) annealed $\frac{1}{2}$ hr. at 650 deg. C. and $\frac{1}{2}$ hr. at 850 deg. C.

any Sunday School library, and that all that was visible to the properly naked human eye was the effigy of many shingles flying through the air. Those who have followed the Cubist and other Post-Impressionistic schools of art will immediately recognize in the accompanying

FIG. 2. ALASKAN SNOWS
Brass (Cu 67, Zn 33) annealed $\frac{1}{2}$ hr. at 550 deg. C. and $\frac{1}{2}$ hr. at 850 deg. C.

microphotographs taken from a paper by F. G. Smith read before the Institute of Metals Division the remarkable designs which develop in twinned crystal forms of certain non-ferrous metals, more especially in brass and alloys of tin.

Fig. 1 indicates, from a Cubist standpoint, a representation of Ajax Defying the Lightning. Ajax will be recognized as standing at the extreme left, in the shadow of a rock in the lower left foreground (which explains his dark color). The lightning is clearly defined in bold zigzag strokes, and the flying timbers at the left indicate a Kansas cyclone. The somewhat exaggerated but subtle note of a blown leaf is rather distinctive of Matisse than of Pares. The real origin of the picture is a field of twinned crystals in brass: (67 per cent Cu, 33 cent Zn) reannealed at 850 deg. C. for $\frac{1}{2}$ hr. after $\frac{1}{2}$ hr. at 650 deg. C.

The same brass reannealed for $\frac{1}{2}$ hr. at 850 deg. C. after $\frac{1}{2}$ hr. at 550 deg. C. reveals a remarkable Cubistic impression of Alaskan Snows. The door of the prospector's cabin is shown on the right, with the surging billows of snow in the foreground on the left. The

FIG. 3. THE APPROACHING STORM
Same as Fig. 2 after 3000 kg. pressure and reannealing

study is full of pathos, showing the cabin door open to the blast, the frail tenement obviously abandoned, while the observer perceives in the visible distance the rear of the dog-sled as it is drawn away. This indicates that the prospector is out of provisions, and is setting forth in quest of food. The sub-title might well be The Drive or Hunger.

The structure shown by a field of the same brass that has been under 3000 kg. pressure after reannealing under the same conditions as in the case of that shown in Fig. 2 is entitled, as a picture, The Approaching Storm. One sees the deluge of rain beating against a

FIG. 4. WOUNDED BIRD IN NEST
Alloy (Sn 70, Sb 20, As 5) etched 12 hr., $\times 4$

wayside signboard on the right, while on the left the lightning flashes through the sky and rends the brown bosom of the earth.

Very different indeed are the results obtained by alloys of tin with arsenic and antimony. The accompanying microphotographs are of crystals found in a ternary system between tin, antimony and arsenic. Fig. 4 shows a Sn 70, Sb 20, and As 5 per cent alloy etched

12 hr., $\times 4$, and reveals the change of cuboidal crystals into curvilinear forms as the arsenic content reaches approximately 5 per cent. The value of these designs in Cubistic art is slight, but if we hark back to the long, curved lines of that phase of draughtsmanship following Aubrey Beardsley and his cult, we find them full of inspiration. We have named Fig. 4 Wounded Bird in Nest. Of course wounded birds do not usually take to their nests, but we claim the privilege of artistic license.

No. 5, which is an alloy of Sn 77, Sb 18, and As 5 per cent, contributed, as in the case of No. 4, by Messrs. Stead and Spencer at a recent meeting of the older organization, the Institute of Metals of Great Britain,

FIG. 6. THE HOST
($\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$)

is a Japanese scene which might be called Morning-Glories in the Rice-fields After a Storm.

We have heard so much of the need of Art courses for students engaged in science and engineering that we offer this sketch to demonstrate that our metallographers are making contributions fully as good as, if not better than, the most advanced of the school of Post-Impressionist painters.

To prove our contention we submit along with the microphotograph of the metallographers a bona fide reproduction of a piece of modern sculpture now on exhibition at the famous galleries of Messrs. Knoedler & Co. on Fifth Avenue, New York. It is entitled "The Host," and is by the well-known artist Elie Nadelman. It stands about two feet in height as we recall the original, and the price in plaster is eight hundred dollars.

University and College Endowment

To the Editor of Chemical & Metallurgical Engineering

SIR:—In these days when the demands upon our income are more multitudinous and insistent than ever before there is greater need and reason than ever that each new claimant present as clearly and convincingly as possible the facts upon which his claim to support is based, and as the Massachusetts Institute of Technology has found it necessary to appeal to its friends for the great sum of \$10,000,000 I shall be grateful if you can allow me the space required to state briefly the case for the Institute and the justifying reasons for this appeal.

The international standing of the Institute as probably the foremost school of technology in the world is generally recognized and further demonstrated by the fact that its student body includes a larger proportion of foreign pupils than any other institution in the country, while the influence of the school upon our own industrial development has been far reaching and profound. This was strikingly brought out at the Congress of Technology held in 1911 in commemoration of the fiftieth anniversary of the signing of the charter of the school. The papers presented by Institute graduates at that time covered the entire field of engineering and science in their applications to industry. The fundamental principles on which the school is founded are the importance of being useful and the way to learn is to do, and these principles have been consistently practiced and developed for more than half a century.

That the community is not unmindful of the value of the Institute training is shown by the recent phenomenal and even embarrassing increase in the number of its students. The magnificent new buildings in which the school is housed were, with what seemed to be ample foresight, designed to accommodate an attendance of 2000, and until this year the student body was well below that figure. This year the number of students has suddenly jumped to more than 3000, thereby straining to the utmost the physical equipment of the school and placing an undue burden upon an already overworked teaching staff.

The devoted and highly trained teachers who constitute the faculty of the Institute have no thought of turning aside from the pressing problems which confront them, but can a self-respecting community continue indefinitely to accept such loyal service without removing the present necessity of sacrifice which it entails? Under normal conditions a member of the teaching staff at the Institute, after an expensive education, is about 30 years of age when he is made assistant professor at a salary of \$2000, and about 40 years of age when he becomes a full professor at \$3000. The average salary of the full professors is now \$3600, and only five out of a staff of nearly 300 receive the maximum salary, which is \$5000. Under the present economic conditions it is obviously difficult and may soon become impossible for men of this capacity to resist the constantly increasing pressure from the industries. Dr. Maclaurin, the president of the Institute, states that if this condition continues for five years the results will be most serious and if it continues for ten years the results will be disastrous. It is to remedy this condition and to provide the new facilities required for housing and training the men who are seeking its instruction and upon whom the industrial future of our country must so largely depend that the school calls

for these new funds and confidently directs that call to all those who believe in the importance of being useful.

ARTHUR D. LITTLE.

Cambridge, Mass.

M.I.T. Alumni Vocations

In connection with the endowment campaign now going on among the alumni and friends of the Massachusetts Institute of Technology, approximate figures have been compiled which indicate the relative distribution of the graduates in industry. It appears that about one-half practice the engineering professions, one-quarter go into manufacturing and the remainder follow lines in which their engineering education can have beneficial application.

There have been 14,000 registered students at Tech. and 7015 graduates, 6000 of whom are included in the following classifications. The groups are somewhat arbitrary and might be re-arranged. However, the subclasses are not definite enough to permit any very detailed deductions. The professional engineers' class is mainly made up as follows:

ENGINEERING PROFESSIONS CLASSIFICATION	
Electrical engineers	560
Teachers of engineering	503
Mechanical engineers	446
Railroad engineers	322
Architects	301
Civil engineers	262
Draftsmen	64
Naval architects	40
Marine engineers	44

The chemical, metallurgical and mining engineers will be included in the manufacturing class because it is assumed that the majority are so engaged. The mechanical engineers are also extensively occupied in manufacturing, and the number so engaged approximately offsets the engineers erroneously included in the following manufacturing classification:

MANUFACTURING CLASSIFICATION	
Mining and metallurgical engineers	351
Miscellaneous manufacturing	350
Manufacturing chemists	252
Steel and iron companies	161
Textile companies	105
Chemists	90
Rubber companies	59
Soap and glue companies	44
Paper companies	40
Gas companies	36
Sugar and starch companies	28
Powder and explosives companies	26
Electrochemical engineers	23

The small number of men reporting themselves as chemists is quite illuminating, when it is considered that several times this number have graduated as chemists. However, this is no reflection on the chemical course given, for it may rightly be assumed that the training of these missing chemists has been such that they could apply themselves more profitably out of the laboratory. The course a man takes does not necessarily have everything to do with his final vocation. David Wesson graduated as a metallurgical engineer, and no doubt he was an able one. However, better opportunities opened up in the edible-oil industry and he applied his thorough Tech. Met. training to this field, with the well known result that the name Wesson has largely supplanted that of olive in the edible-oil industry.

The benefit of our technical institutions to the community is much broader than can ever be appreciated, and it is hoped that the community will generously square up a few of the silent but evident bills receivable now held against it.

National Conference of Business Paper Editors

Responding to the call issued by Samuel O. Dunn, president of The Associated Business Papers, Inc., in pursuance of the resolution adopted by the executive committee of The Associated Business Papers, Inc., at New York, Oct. 6, 1919, 67 editors and editorial representatives assembled at the Hotel Astor, New York City, Nov. 13, to consider the formation of an editorial conference of The Associated Business Papers, Inc. It was decided to form a National Conference of Business Paper Editors, the purpose of which is:

To provide an organization for the discussion and formulation of constructive editorial policies, held in common by the business press; to furnish the medium for disseminating the results of these discussions through co-operation; to provide by close contact of the editors, inspiration for editorial achievement and the fuller realization of the existing individual and collective responsibility as leaders of thought in the industries they serve; and to perform such other functions as may further the aims of this Conference.

The officers elected are: President, A. I. Findley, *Iron Age*, New York; vice president, Clay Cooper, *Mill Supplies*, Chicago; secretary-treasurer, R. Dawson Hall, *Coal Age*, New York; executive committee, J. C. Chase, *Class Journal Co.*, New York; B. O. Hough, *American Exporter*, New York; W. R. McQuilkin, *National Builder*, Chicago; E. T. Hawson, *Railway Maintenance Engineer*, Chicago; C. J. Stark, *Iron Trade Review*, Cleveland; Harvey Whipple, *Concrete*, Detroit.

There will be three meetings each year, one in midwinter, one in the spring and the third in conjunction with the annual meeting of The Associated Business Papers, Inc. One of the two editorial meetings will be held in the East and the other in the West. Special meetings may be called at the discretion of the executive committee.

The time and place for the midwinter meeting was left to the discretion of the executive committee.

Extension of Trading-With-the-Enemy Act

Continuation of the trading-with-the-enemy act until Jan. 15 has been provided by a joint resolution passed by the Senate and the House of Representatives. The resolution was made necessary because of the possibility of ratification of the Peace Treaty by the Senate. Ratification of the Treaty would terminate the trading-with-the-enemy act and would permit the dumping of German dyes, as no law has been enacted to protect the domestic dye industry. While the House has enacted such legislation, the Senate, due to the consideration of the Peace Treaty, was unable to take up the consideration of the dyestuffs bill. The resolution which has been adopted by the two houses provides "That notwithstanding the prior termination of the present war, the provisions of the trading-with-the-enemy act, approved Oct. 6, 1917, and of any proclamation of the President issued in pursuance thereof, which prohibit or control the importation into the United States of dyes or other products derived directly or indirectly from coal tar, are continued until Jan. 15, 1920." The only objection which was offered, and that later was withdrawn, was caused by a telegram from a textile manufacturer which read as follows: "Very important for cotton mill industry that foreign fast color dyes are admitted without further delay or hindrance. One cotton manufacturer has a

million and a half dollars worth of shirting cloth requiring these dyes. He is unable to deliver it without the dye. Meanwhile many million dollars worth of these shirtings with fast dyes recently have been bought in England for importation to this country. Our print works has many thousand pieces held up for lack of fast colors. We certainly will lose our export trade in shirting unless permitted to secure dyes available to foreign competitors."

During the discussion of the resolution, it was stated on the floor of the Senate that the War Trade section of the State Department is not functioning as efficiently as it should. It is anticipated that the resolution will have to be extended, as it is not probable that the consideration of the dyestuffs bill will have been completed by Jan. 15. The Senate is unalterably opposed to the licensing system, and Senator Smoot of Utah, as strong a protectionist as he is, declared in the course of the debate that he would not vote for a license system even though he knows it to be necessary to the protection of the dyestuffs industry.

Anti-Tuberculosis Campaign

While science is making rapid strides in chemistry, adding each year to the productivity and comfort of the civilized world, the physical vigor of that world is threatened by an insidious disease. The centuries-old plague—tuberculosis—is now killing hundreds of thousands of persons and incapacitating millions every year in three big nations for which reliable figures are available. In each of these nations, Great Britain, France and the United States, a determined effort is being made to check the ravages of the disease, which, experts agree, is not hereditary and is both preventable and curable.

The death toll in the United States is 150,000 a year, the active cases number more than 1,000,000 and the unsuspected cases greatly exceed the known. To combat this menace the National Tuberculosis Association has undertaken an intensive campaign on such a scale as to warrant expectations of saving tens of thousands of lives and averting the physical breakdown of many thousands of workers as the result of a year's work. The amount required for a nation-wide drive against the "White Plague" will be approximately \$6,500,000, which fund will be raised during December by the sale of Red Cross Christmas seals at a penny each.

Working in co-operation with its 1000 affiliated State and local organizations, the National Tuberculosis Association plans to carry to the great masses of the people the simple truths regarding the disease—that it is most effectively fought by fresh air, scrupulous cleanliness and good food, which build up the bodily resistance against disease germs. Employers are to be impressed with the necessity of keeping up to the minute in providing protective devices against dust and dyes and impure air, which weaken the lungs and thereby increase the danger of tuberculosis. Physicians everywhere will be asked to redouble their efforts to search out unsuspected cases, and communities will be urged to provide clinics, dispensaries, hospitals and sanatoria in sufficient numbers to assure proper treatment for all afflicted persons. By such means it is believed that a long step will be taken to the great goal, which is the bringing of the disease under complete control.

Savannah Meeting of the American Institute of Chemical Engineers

Report of the Annual Meeting Held at Savannah, Georgia—Election of Officers—Address of President-Elect David Wesson on the History and Development of the Cottonseed Oil Industry—Excursions

FOR several reasons the selection of Savannah is preference to one of the usual convention centers for the twelfth annual meeting of the American Institute of Chemical Engineers proved to be a very happy one. The four days, Dec. 3-6, were ideal, thus adding to the pleasure of those in attendance while getting better acquainted with one another as well as with the hospitality of Georgia. It was peculiarly fitting that recognition should be made on the twentieth anniversary of the process of refining cottonseed oil as devised and first operated in Savannah by the Institute's president-elect, Dr. David Wesson.

The commodious tourist hotel DeSoto was opened in advance of the usual winter season schedule especially, that its homelike attractions might give the meeting seclusion and an atmosphere of a great family gathering. The Hon. Murray M. Stewart, mayor of the city, gave the address of welcome, to which President Arthur D. Little responded. The reports of committees were received. That on the canvass of ballots reported the following officers elected:

President, David Wesson; first vice-president, Henry Howard; second vice-president, Albert W. Smith; third vice-president, Hugh K. Moore; secretary, John C. Olsen; treasurer, F. W. Frerichs; auditor, C. F. McKenna.

In the annual report of Secretary Olsen, it was stated that the total membership of the Institute had reached 344. This led to considerable discussion. Dr. Little stated that there were at least 2000 chemical engineers in this country and with such a restricted membership the society could not be considered as unqualifiedly representing the profession. It was finally decided that the council, when it seemed desirable, could waive any or all the qualifications required by the constitution for an applicant to have his name placed on the ballot. This

was especially designed to bring into the society certain men of undoubted professional qualifications and attainments now disqualified.

Resolutions were passed indorsing the Longworth bill providing for the licensing system on dye importations, and immediately forwarded to the Senate. Longer and more thorough courses in chemistry and engineering were recommended for technical students.

Because of the attractions provided by the entertainment committee headed by Mr. Frank N. Smalley, the sessions allotted for the reading of papers were not allowed to take their usual dominant position. The available time was used in reading selections which were then discussed. Space will not now be devoted to the details of this part of the program, as nearly all the manuscripts will be published in full at an early date, collectively in the semi-annual *Transactions* of the Institute and separately in subsequent issues of this and other journals. The addresses of the retiring and incoming presidents, Doctors Arthur D. Little and David Wesson, dealt especially with the South. The former will be published in full in a later issue, while the latter is given herewith, in part.

NOTES ON EXCURSIONS

The weather was favorable for the excursions, which were both pleasant and instructive. A motor trip to Bethesda (Wednesday), a steamer trip on the Savannah River with stopover at Port Wentworth's lumber mill, sulphate pine pulp mill and shipyard and at various warehouses along the route (Thursday), visits to the plants of the Southern Cotton Oil Co. and the American Agricultural Chemical Co. (Friday), all contributed to make these side lines of the annual meeting long to be remembered.

History and Development of the Cottonseed Oil Industry

BY DAVID WESSON

It seems particularly appropriate at this first meeting of the Institute of Chemical Engineers in a Southern city that an effort should be made to tell the story of how a great industry has been founded and built up on what was once a by-product and a nuisance.

The early records do not tell us much. We find in the statistics of South Carolina published in 1826 that Dr. Benjamin Waring established a mill at Columbia, S. C., and expressed from cottonseed a very good oil. Georgia had an oil mill in 1832, but little is known about it. C. D. Arfwedson, an English traveler, in his book entitled "The United States and Canada, 1832, 1833 and 1834," states, "In many places it is usual to manure the fields with the seed not used for planting, but of late years experience has taught the planters to set a higher price on it, as it contains a considerable quantity of oil which is extracted by pressure and is suitable both for burning and painting. The oil may in the course of years become an additional source of wealth to the planters."

Up to the time of the Civil War and in fact for some time after, the disposal of the seed was always more or less of a problem. Much of it was used for fertilizer, and a great deal of it was thrown into the water courses. In 1857 the State of Mississippi passed laws fining gin owners who allowed seed to accumulate at gins located near towns and villages, where it was apt to become a nuisance. The fine was \$20 per day after the fifth day. Another law imposed a fine of \$200 for throwing the seed into water courses the waters of which were used for drinking and fishing.

The industry began to assume some importance just prior to the Civil War, after which it commenced to grow. In 1860 there were seven factories employing 183 workers. In 1870 26 factories employed 644 workers, while today about 900 factories give employment to about 20,000 workers and 5000 officers and other salaried men.

The causes for the rapid growth of the industry are various.

First, the rapid increase of population all over the

civilized world made increased demands for food. The doing away with the large cattle ranches of the West reduced the meat supply so that the hogs which formerly furnished an adequate supply of lard were more and more eaten as pork and a demand was made for an edible fat to replace the lard. This demand is largely met at this time by cottonseed oil and the growth of the cottonseed oil industry is largely coincident with the decrease per capita of the hog lard supply.

Second, the cottonseed oil produced in the early days of the industry was very irregular in quality. In 1879 it was used in small quantities to adulterate lard, but the quality was such that it did not improve the mixture. The application of chemistry to the industry at this time started it upon a rational basis and gave such a stimulus that it has grown by leaps and bounds ever since. The advent of the chemist started improvements in the quality of the oil and at the same time pointed the way to economies in production.

The most important work of the chemist has been in refining the oil and improving the products made therefrom. To do this principles had to be established in the laboratory and applied in the factory.

EARLY REFINERIES

The first crude oil was used for paint and burning in lamps. The early refineries kept their methods so secret that it has been difficult to discover when oil was first refined in this country. The writer remembers being told in 1870 that peanuts were pressed to obtain oil which was mixed with that of the cottonseed and sold for olive oil.

The early refineries were connected with the oil mills, but there soon arose people who recognized that refining the crude oil as furnished by the mills was an industry by itself and refineries started in several places.

The crude oil in the early '80s was sold on color and flavor and in case of disputes referred to committees. About this time the chemists discovered that free fatty acid in the crude oil was an index of quality and refining loss and applied the test in judging value of samples. A small-laboratory refining test was made to see if the samples of crude would refine to a good color. The writer used this method in Chicago in 1887 and when in 1890 he commenced to reject oil in New York on

account of high acidity he encountered much opposition, some mill owners protesting that they had never had any fatty acids on their premises.

Shortly after 1880 cottonseed oil began coming to Chicago in considerable quantities. Here it was refined with caustic soda, bleached with fuller's earth, mixed with prime steam lard and oleo stearine and went into commerce as refined lard. In 1887 it was discovered that more lard was shipped from Chicago than came there either on the hogs killed there or as lard itself. Congress started an investigation and discovered that cottonseed oil was the cause of this great increase. They also discovered that the 30 to 40 per cent of oil in the compounds did not injure them from a health standpoint, though the oil used at that time did not improve the flavor.

About 1892 or 1893 the practice of deodorizing was started in Chicago. This consisted in heating the oil in a tank provided with a large steam coil and then blowing live steam through the oil to remove flavor and odor. The oil was afterward cooled to normal temperature. This process, while producing a greatly improved oil, did not turn out a perfect one by any means. It allowed the lard substitute maker, however, to use a mixture of about 82 per cent oil and 18 per cent oleo stearine, which proved quite satisfactory to the trade.

THE WESSON PROCESS

In 1899 the "Wesson process," so called, was discovered and the first plant was put in operation in Savannah the following year. The product of this plant set a new standard for cottonseed oil, which has now become the chief source of edible fat next to butter in this country. From the discovery of the Wesson process to about 1910, lard substitutes were made almost entirely of mixtures of oleo stearine and deodorized cottonseed oil. The packer controlling the former put its price very high and the demand for a cheaper material was supplied by the discovery of the hydrogenation process which fulfilled the dream of the fats chemist by furnishing a ready means of saturating the double bonds of the fluid oils with hydrogen and converting olein and linolein to stearine. By passing hydrogen gas through oil at a temperature of 180 to 200 deg. C. in the presence of finely divided nickel, cottonseed oil can be hardened to any extent up to a melting point of about 60 deg. C.

The lard substitutes of the present day are almost entirely produced either by partly hardening the whole oil or by adding sufficient completely hardened oil to that which has not been so treated. Besides the use of the oil in lard substitutes, which utilizes at present about 75 per cent of the total production, large quantities are used for table oils, oleomargarine, or margarine, as it is called in Europe. Considerable oil is also used in medicine.

In refining the oil an average of 9 per cent is taken out by the alkali in the form of soap stock. In the early days this was made into cheap laundry and mill soaps. Later it was made into washing powder by first saponifying and washing, then mixing with soda ash or sal-soda. At best the soaps made directly from the soap stock were poor in color and possessed an unpleasant odor. It is the practice in several large plants to decompose the soap stock with acid, then saponify by the Twitchell process or otherwise and distill the fatty acids from the black elastic pitch which remains. This pitch is used in making paints used for roofing. During the

war considerable quantities of glycerine were recovered from the soap stock, but on account of changed conditions it has been found better to treat the soap stock with centrifugal machines of the cream separator type and recover a considerable quantity of the entrained neutral oil.

EARLY CRUDE OIL MILL PRACTICE

The first crude oil mills were somewhat primitive compared with those of the present day. No attempt was made to separate the lint from the seed before passing through the hullers. In those days the seed carried so much lint it was customary to figure meats and hulls as equal in quantity. The early mills burned the hulls under the boilers together with the trash in the seed. The separation was very poor and the hulls frequently carried large quantities of uncut seed and meats which heaped account for the high hull percentage.

The separated meats were crushed between rolls, cooked in jacketed heaters and pressed in box presses provided with thick camelshair mats between which the bags holding the meats were placed. The yield of oil was small, a large amount being left in the cake and lost with the meats which went into the hulls.

An important by-product of the old-time mills was hull ashes, which amounted to about 20 lb. per ton of hulls and were rich in potash and phosphoric acid. Actually the ash present was several times that recovered. On account of the character of the hulls much of the ash was carried up chimney. About 1887 it was found that the hulls could be used for fodder and cows have been eating them at increasing prices ever since. At the same time plat presses superseded the old boxes and better work was done in the press rooms. Linter or linter gins were also installed and the short fibers or lint was partly removed from the seed before hulling.

In 1887 the writer started a small laboratory in Chicago for analyzing mill products for the American Cotton Oil Co., which had just come into existence. The results on 244 samples of cake showed an average of 13.55 per cent oil, while 226 samples of meal averaged 12.18 per cent. Hulls were not analyzed, but inspected for meats and uncut seed. This was the beginning of mill control work in the industry. It has caused great economies and pointed the way to the use of better machinery. At the present time the meal runs from 6 to 7 per cent oil.

The cottonseed cake has always been either exported as such or ground into meal and used as a cattle food or fertilizer. One of the latest developments is the extraction of the oil from the cake and meal by solvents. At present prices this is a profitable industry. There is no good reason why solvent extraction should not be applied to the entire meats, cutting out the press-room expense and recovering 50 to 60 lb. of oil per ton of seed. If this were done it would have saved last year nearly 500,000 bbl. of oil, worth about \$34,000,000. There is nothing to prevent this development except fear of fire risk and investment of capital. It is a comparatively simple engineering problem which many of us will doubtless live to see accomplished.

Owing to war conditions many oil-bearing materials and oils have been brought to this country and handled in the cotton oil mills and refineries. So great has been the variety and quantity of these different oils that it would seem more proper at the present time and in the future to talk of the vegetable industry.

Commercial Possibilities in the Electrochemical Production of Organic Compounds*

Description of Prospective Industrial Applications of Organic Electrochemistry—Advantages and Disadvantages Inherent in Electrochemical Methods—Conditions Favoring Economy in Operation, Catalytic Effect, Diaphragms—Some Suggested Organic Electrosyntheses—Status of the Industry

By C. J. THATCHER, PH.D.

WE ALL know that, in industrial applications at least, the electrochemistry of the organic compounds has not kept pace with the progress in other lines of electrochemical activity. Probably most of us would have difficulty in naming more than a few organic compounds which have been successfully manufactured by electrochemical methods, at least in this country. Indeed, progress in this direction has been so restricted that there has been, or seems to be, hardly any interest in this branch of the electrochemical industry.

It is true that in February, 1915, this Society held a symposium consisting of three papers on the subject of organic electrochemical manufacturing, followed by a discussion in which a number of members took part. Both optimistic and pessimistic opinions regarding the future were expressed in the papers and discussions. Whatever may have been the general consensus of opinion, it is certain that the symposium did not cause any noticeable activity in the electrochemical production of the carbon compounds despite the apparently favorable opportunity presented by the war. At that time I myself was preparing to manufacture and have since manufactured, electrochemically, several tons of paramidophenol sulphate—an intermediate and a photographic developer—and have also since then made anthraquinone and hydroquinone on a small-factory scale; but no other serious attempts to establish organic electrochemical operations during the war now ended have come to my attention.

Perhaps the period intervening since that symposium has not been the most propitious; for old and established processes were almost certain to bring needed and highly profitable results, and there was little or no time for laboratory or plant experimentation. However, that period is now passed, and enterprising American manufacturers are again confronted with the necessity for improvement and economy in production, in order that they may keep ahead of domestic and foreign competition.

PROSPECTIVE INDUSTRIAL APPLICATIONS OF ORGANIC ELECTROCHEMISTRY

Since it is in the new and comparatively favored field of dyestuff and other organic products that industrial preparedness against foreign competition will be most necessary, it would seem that we electrochemists should now seriously consider, with an open mind, whether we cannot blaze a path in this as we have in other directions. We do not need to be reminded that Yankee optimism, courage and ingenuity have, when once aroused, turned failures into successes, and confounded the wise

in other countries. Our friends the enemy—in war as in chemistry—have had recent surprises along that line in the Argonne and elsewhere.

Now we have not really tried to manufacture organic derivatives here electrochemically. There is much that we do not know about what has been done or tried in other countries, particularly in Germany. But the mere fact—if it be a fact—that others have tried or failed does not conclusively prove anything as to what the American electrochemist can do.

The real question, which we ought to consider in all seriousness, is whether now and in this country are not the time and place to begin more or less extensive industrial applications of organic electrochemistry. To awaken some sustained interest, consideration and discussion of this question in this or other meetings is the object of my paper, and for this purpose I would ask you to consider, first, the basic principles which may indicate the kind of electrochemical operation which could be expected to be successful commercially; and thereafter to briefly consider specific electrochemical processes.

ECONOMIC BASIS OF ORGANIC ELECTROCHEMISTRY

To this end we may inquire first as to how economic values are created by industrial electrochemistry. That is a question which Dr. Roeber considered in his presidential address before this Society in April, 1914, and it seems well to apply some of Dr. Roeber's considerations to the subject of this paper.

Economic values are created by industrial electrochemistry—as in other similar lines of activity—either as time value, place value, or form value. Time or place value of organic electrochemical products is mainly due to their high energy content, which can be imparted to them more economically by the electric current. Such products are valuable mainly because they enable us to transmit their stored energy to another time or place. Calcium carbide and aluminum when used in aluminothermic reactions are examples of electrochemical products having a high time and place value. Their potential energy becomes kinetic whenever or wherever desired. These and other products of electrochemical industries acquire their economic value by serving as a medium for electrochemical power transmission. Many or most of this class of products are made by electrothermic methods.

But another and important class of electrochemical products has nothing to do with chemical power transmission. These are products which have a high form value, i. e., those which derive their intrinsic value from the mechanical and chemical work expended and dissipated in transforming the raw materials into the de-

*Read at the Chicago meeting of the American Electrochemical Society, Sept. 26, 1919.

sired finished product. Qualities other than a high specific content of energy impart the economic value to this class of compounds. Caustic soda, bleaching powder and electrolytically refined copper are examples. Such products are made by electrolysis, for the most part; they have a high form value due to the work expended during electrolysis upon comparatively cheap raw material. In the production of nitric acid or nitrates by atmospheric fixation, the raw material, air, is more than cheap, it has no economic value, we may say. Therefore the form value of nitric acid and nitrates so produced is unusually high.

On the basis of past experience, and reasoning by analogy, we may conclude, therefore, that products which have a high form value are such as stand the best chance of being economically produced by electrolytic methods. The comparatively wide margin between the value of the raw material and the finished product permits a considerable saving whenever electrolytic methods reduce the cost of the mechanical and chemical work put into the operation. This comparatively large saving often more than offsets the interest and other charges due to the design and construction of electrochemical equipment.

This somewhat abstruse consideration has a very practical bearing upon the subject of this paper, for it will help to decide whether electrochemical methods of production may be expected to be economical in the manufacture of organic compounds, and it should enable us to tackle the problem along the lines of least resistance. Electrothermic methods are almost but not quite excluded in the manufacture of the carbon compounds. It is in the technical applications of electrolysis that electrochemical operations should succeed if at all. And our prior consideration teaches that a very large number of organic compounds should be capable of being produced electrochemically, because of the vast number of organic compounds which have a high form value. The carbon compounds (particularly the aromatic compounds, such as dyestuffs) have a high form value, more so than inorganic compounds as a class. The average high value of such compounds is not due to a high energy content, nor to the value of the organic raw material, which is often comparatively low. Their value is due, rather, to the amount of manual, mechanical and chemical energy expended and dissipated in transforming the relatively cheap raw materials or intermediate into pure, finished product. And we have seen that just such transformations are a most promising field for industrial electrolytic operations.

We are forced to conclude, therefore, that the basic economic principles are favorable for the profitable production, by electrochemical methods, of a very large number of organic chemicals—all such as have a high form value.

ADVANTAGES WHICH MAY INHERE IN ELECTROCHEMICAL METHODS

Obviously, in the final analysis, electrochemical methods are advantageous only when they are more economical. But economy may be due to several causes. We will consider only the production of known products already in demand, and now produced by chemical methods, and not new compounds which the characteristics of the electrode processes might enable us to produce.

Electrochemical methods may supplant chemical methods:

First: When the same organic raw material is used.

(a) By increasing the yield through control of conditions to be later considered.

(b) By eliminating inorganic raw materials such as oxidizing or reducing agents, as by substituting electrolytically generated oxygen and hydrogen.

(c) By electrolytic regeneration of inorganic raw materials, as for example spent chromic acid liquors.

Calculation will show that with but few exceptions, it is cheaper to oxidize, reduce or substitute by electrolytic than by chemical means, a fact which was brought out by Mr. Liddbury in the symposium previously referred to¹.

This is particularly true when, as is sometimes possible, both the anode and cathode reactions may be made to perform useful work, either in the preparation of the same or different organic products.

But even without such possible economy, electrochemical transformations, figured on an equivalent basis, are usually surprisingly cheaper. For example, with power at metropolitan rates, it costs about ten times as much to oxidize with bichromate as at the anode of a well designed cell. And if an electrolytic oxidation saves 35c. per lb. buying power at metropolitan rates, it is not necessary and may not pay to locate the plant in an inaccessible locality in order to use hydro-electric power at an additional saving of only a few cents per pound.

Whenever, therefore, electrolytic oxygen, hydrogen, chlorine, etc., give as good a yield per unit of organic raw material, we have every reason to expect economy. For any increased charges, inherent in the use of electrolytic equipment, such as interest and depreciation, need not, if the cell is properly designed, be enough nearly to eliminate the economy in favor of the electrolytic method.

There are numerous organic compounds now prepared chemically by oxidation, reduction or substitution, which, by skillful control of conditions in a properly designed cell, can be more economically made electrochemically from the same raw materials as those now used, for one or more of the reasons specified above. Only poor yields, excessive depreciation, etc., can prevent success, and it will be shown that improvement in these particulars can be effected.

Secondly: When a cheaper organic raw material may be used.

It would carry us beyond the scope of this paper to consider the various instances in which such a substitution may be made. Briefly stated, the conditions obtaining at the surface of an electrode are much more variable and controllable than in purely chemical transformations, so that new reactions can be used technically, or a number of intermediate steps may be combined into one operation.

One of the features of electrode processes which accounts for the economy thereby effected is the wide range of gas pressure obtainable at the surface of an electrode by suitable variation of the electrode potential. Referring to this point, Prof. Nernst stated² that it was possible to liberate a gas, such as chlorine, at the anode either in greater than homeopathic dilution or at

¹Met. & Chem. Eng., vol. 13, No. 4, p. 211; April, 1915.

²Berichte, 1897, p. 1562.

pressures which amount to millions of atmospheres, and that this vast range of pressure made it possible to readily chlorinate organic compounds to every conceivable degree. The importance of the regulation of gas pressure in organic synthesis has been shown in many hundreds of instances. Thus, in organic substitution processes, the number of substituted atoms is often dependent upon the pressure at which the reaction occurs. Since any desired pressure can be so conveniently created, and maintained at an electrode, solely by variation in electrode potential, it is obvious that electrochemical methods should frequently be more direct and economical. As Prof. Haber once stated:

"Whereas the nucleus of the aromatic compound is not attacked by most chemical oxidizing materials, or is completely destroyed, accompanied by the disruption of the ring, electrolysis under favorable conditions permits a smooth oxidation, with the result that the hydroxyl group is introduced into the benzol nucleus. Benzol is thus oxidized in sulphuric acid solution at the anode to hydroquinone, aniline to paramidophenol, azobenzol to tetraoxybenzol, anthracene to alizarine."

No explanation of the economy resulting from such direct syntheses of coal-tar crudes is needed.

Thirdly: When a high degree of purity is desirable.

We can oxidize or reduce by electrical energy without contaminating the finished product by foreign materials the complete removal of which is generally troublesome and expensive.

The three general considerations above outlined should be sufficient to show why it will be advantageous and economical to use electrochemical methods in manufacturing organic compounds. And we have also seen that the use of such methods may be expected to be successful in the manufacture of products having a high form value. Let us consider the other side briefly.

DISADVANTAGES WHICH MAY INHERE IN ELECTROCHEMICAL METHODS

The objections to the commercial use of electrochemical methods in preparing organic compounds were very concisely stated at the symposium in 1915, by Mr. Lidbury, in the following words:

"In the first place, to do a unit of chemical work in a unit of time, the electrolytic plant would be usually very much larger than a chemical plant; require very much more room; be usually very much more expensive; require more expert attention, and on account of the extreme severity of the demands of electrolytic methods on materials employed for plant, etc., the upkeep would usually be higher.

"In the second place, the working out of an electrolytic method requires a very much greater amount of time, thought, intelligence and expenditure than the working out of a chemical method. Though this might not amount to much as regards laboratory investigation, anyone acquainted with the electrochemical industry would be aware of the greater difficulties which invariably have to be overcome in preparing such a process for large-scale operation, and in that important phase known as 'establishing practice.'"

I am not sure that we can all agree as to the validity of the first of these objections. However, is it not a fact that such objections could be raised against the adoption of any electrolytic process, inorganic as well as organic? It would seem that almost any electro-

chemical plant is necessarily larger and is more expensive to design, construct, establish, practice and maintain. We cannot deny the commercial practicability of organic electrolytic plants upon grounds which would deny the practicability of existing successful electrolytic plants. Wherever, for reasons already given, there is any considerable economy of operation in electrolytic methods, higher interest charges due to greater expense in the design, equipment and maintenance of an electrolytic plant are more than offset, at least in any plant producing annually 100,000 lb. or more of an organic product.

CONDITIONS FAVORING ECONOMY IN OPERATION

Electrochemical methods of production are, of course, only economical when operated under skillfully selected and controlled conditions. It is not my purpose to consider such conditions at any great length in this paper. They include electrode material, chemical and electrical conditions, catalytic effects and diaphragm material. Excepting the latter two the complexity and range of variation are too great to be considered advantageously in any general manner. But it will be worth while to consider briefly factors capable of a more general consideration, such as catalytic effects and the use and nature of diaphragms.

CATALYTIC EFFECTS

The nature and importance of catalytic action upon electrode processes were set forth by Prof. Ostwald with customary insight in his paper presented at the International Electrical Congress at St. Louis in 1904¹. A few quotations from this paper will be most instructive. Prof. Ostwald stated:

"If there are several possibilities for the reaction at one electrode, the readily occurring chemical reaction depends not only on the nature of the possible chemical reactions, but upon the concentration of the substances which are present, and by suitably varying the latter we can bring any reaction to any point in the voltage series."

"In connection with this it should be emphasized that what is called briefly '*the electrode process*' is in reality a rather complex phenomenon."

"It will thus be seen that even the simplest electrode reactions are made up of a plurality of reactions following each other step by step. Since each of the same can be influenced catalytically, it is already evident that a very great variety of results is possible."

"Such means of changing the speed of a given reaction within very wide limits exists really in chemistry in what is called *catalyzers*. Herefrom it is at once evident which very important and essential part the catalyzers are able to play in electrolytic action. By retarding one of the possible reactions by means of a negative or retarding catalyzer, we are able to *exclude* its influence from the electrolytic process. By accelerating by means of a catalyzer a reaction which is of itself slow, we can *include* it into the electrolytic process. In other words, we are no longer compelled to let the current act in the way stated by the above simple law, but in principle we are now able, by applying suitable catalyzers, to prescribe to the current that reaction which we want to take place, and it does not matter at which point in the voltage series this reaction is situ-

¹Electrochemical Industry (Now MET. & CHEM. ENG.), vol. 2, No. 10, p. 393; October, 1904.

ated. This fundamental idea may be applied in two directions. First, in synthetic work; if we suppress by negative catalyzers those reactions which would take place before the desired one, we can bring the desired reaction to the front, or if the reactions which take place before the desired one take place with a low speed, we can accelerate the speed of the desired reaction by means of a positive catalyzer and can thus produce the same effect. The second application is for *analyzing the reactions which really take place at the electrodes.*"

The improvements which may be effected in industrial organic syntheses by suitable control of catalytic action is sufficiently outlined for present purposes in the foregoing. A more detailed consideration of the subject will be found in Prof. Ostwald's paper, in President Bancroft's recent address on "Poisoning of Catalytic Agents", and in papers⁴ describing my investigations in Prof. Ostwald's laboratories which called his attention to the subject.

USE AND NATURE OF DIAPHRAGMS

It is probable that the need of suitable diaphragms for an electrolytic cell for the manufacture of organic compounds has hindered the development of the industry as much as or more than any other factor. On account of the nature of organic compounds, many of which are either insoluble or non-electrolytes, it is usually necessary to employ a solvent electrolyte, which tends to disintegrate diaphragms so rapidly as to prohibit commercial operations. Few materials suitable for diaphragms will withstand the corrosive effect of strong acids, alkalis or oxidizing liquids for any length of time. Other materials which might be more resistant become clogged during use, accompanied by a prohibitive increase in resistance.

I encountered such difficulties at the outset of my own organic electrochemical manufacturing, and was obliged to devise a diaphragm suitable for the purpose. This diaphragm, known as Electro-Filtros, has been in commercial use in organic electrochemical operations since 1915; and experience has shown that it is absolutely permanent in acid and neutral solutions and adapted to the purpose. It is described in METALLURGICAL & CHEMICAL ENGINEERING, May, 1915, pages 336-338, and is manufactured and sold by the General Filtration Co. It is not suitable for use in strong alkalis; but organic electrolytic operations involving the use of any other kind of solvent need not be unsuccessful through lack of a suitable diaphragm.

SOME SUGGESTED ORGANIC ELECTROSYNTHESES

Approximately 150 patents have been granted, most of them prior to 1910, for electrochemical processes producing organic compounds. The bulk of these are German patents, which fact alone tends to indicate the interest in Germany in this line. A list of a few of these and other suggested organic compounds will be sufficient for the purpose of this paper; but in preparing the list it has not been restricted to preparations of known or proved commercial practicability.

With this understanding it might be said that the following offer some possibilities: Alcohols, aldehydes and ketones of fatty acids, iodoform, vanillin, chloral,

azo and hydrazo compounds, oxidation products of fusel oils, dyestuffs of the triphenylmethane type, aniline blue, aniline black, Hofmann's violet, anthraquinone, alizarine, congo red, orange II, sulpho acids, piperidine, dihydroquinoline, benzidine, amidophenol, chlorbenzols, quinone, hydroquinone, saccharine and phthalic acid.

STATUS OF THE INDUSTRY

The technology of organic electrochemistry has, of course, reached its greatest development in Germany, as a natural consequence of Germany's attention to the organic field. The great secrecy maintained there in this line has made it impossible to obtain exact knowledge regarding the status of the industry. It has been stated on good authority that chloral, vanillin, iodoform, azo and hydrazo compounds have been profitably manufactured electrochemically and that one concern at least was, prior to the war, operating a large electrochemical plant devoted to the production of anthraquinone.

In Switzerland, according to my information, at least one electrolytic plant has been engaged in the production of chloroform, chloral and phosphorous chlorides, and has been utilizing electrolytic chlorine in the manufacture of synthetic indigo.

If there have been any extensive developments in this country they have escaped my attention, excepting the use of electrolytic chlorine for the indirect production of monochlorobenzol and dichlorobenzol and similar organic compounds. As already stated, I myself have made several tons of photographic developers electrochemically in the last few years and have produced hydroquinone and anthraquinone on a small-factory scale.

One of the greatest obstacles to the progress of the industry has been the scepticism of manufacturers and financiers regarding the possibilities. That, however, is nothing unusual, for it was not many years ago that the manufacture of steel in the electric furnace was ridiculed by both manufacturers and technologists. The next ten years or so will witness a development of the organic electrochemical industry which will surprise many, for, as has been shown in this paper, the underlying economic principles are favorable.

Cotton Consumption During Fiscal Years 1918 and 1919

The consumption of cotton during the year ended July 31, 1919, was 5,767,519 bales, against 6,566,489 bales during the previous year. Linters consumed amounted to 455,337 bales in 1919 and 1,118,840 bales in 1918.

Imports of foreign cotton during July were 19,403 bales of 500 lb. in 1919 and 25,002 bales in 1918. Imports for the year ended July 31 reached 201,586 bales in 1919 and 221,216 bales in 1918.

The exports of domestic cotton and linters during July, 1919, amounted to 528,902 bales, against 218,877 bales in July, 1918. The total export for the twelve months ended July 31, 1919, was 5,605,736 bales, against 4,476,124 bales for the previous year. These figures include 1879 bales of linters exported during July in 1919 and 16,802 bales in 1918 and 71,534 bales for the year ended July 31 in 1919 and 187,704 bales in 1918.—*Fortnightly Information Review*, Nov. 1, 1919.

Stretched Wire Apparatus for Measuring Thermal Expansions

BY ARTIUR W. GRAY

DETERMINATIONS of linear thermal expansivity involve:

- (1) Production of temperature uniformity.
- (2) Determination of temperature.
- (3) Measurement of small length changes.

Of these, the last is by far the most difficult.

DIFFICULTIES IN MAKING RELIABLE MEASUREMENTS

The difficulties that arise in connection with the measurement of length changes are of two kinds:

First, the displacements are generally so small that in order to attain even moderate percentage accuracy, high absolute accuracy is necessary. It is comparatively easy to arrange devices of sensitivity sufficient to indicate displacements smaller than one-tenth of a micron; but it is not quite so easy to attain such precision upon repeated attempts to measure the same length. It is not at all easy to make sure that such precision, when attained, represents real accuracy, that is to say, correctness.

In the second place, measurements of thermal expansions are far more difficult than ordinary length measurements requiring the same degree of accuracy. The very nature of the case demands that the body under investigation be measured at several different temperatures; and changes of temperature are always accompanied by displacements in various parts of the measuring apparatus. Unless special precautions are taken, these displacements give rise to errors which are always difficult, and often quite impossible, to determine with certainty. So-called compensating devices are generally unreliable. Rather than trust them when accuracy is of importance, it is better to design apparatus which will render the errors negligible, or at least will make them determinable with certainty.

It was for the reasons just given that the writer introduced the use of stretched wires in 1911 when designing for the Bureau of Standards the equipment still used in determining the thermal expansivity of materials in the form of bars.

STRETCHED WIRE METHOD FOR MEASURING LINEAR DISPLACEMENTS

With the aid of such a simple device as a tightly stretched fine wire it is fairly easy to measure with great accuracy a displacement which occurs within a region otherwise difficult of access.¹

Apparatus on this principle has been employed for the past eight years in the determination of thermal expansions. Two such arrangements of stretched wires are represented diagrammatically by Figs. 1 and 2. In each the expanding bar is indicated by *AB*. In Fig. 1, wires are freely suspended in contact with the ends of the bar and are stretched vertically by the weight of vanes immersed in oil, the viscosity of which

is adjusted to damp any swinging of the wires so that their motions will be almost, but not quite, aperiodic. In Fig. 2, suitable for cases in which the bar is immersed in a liquid, wires are stretched upward to another bar *CD* rigidly connected with the central portion of *AB*. In both arrangements the transverse motions of the wires are observed through micrometer microscopes focused at convenient points *E* and *F*. Disturbances from changes in level are avoided by grinding ends of *AB* to form portions of a horizontal cylinder, the axis of which passes through the center of the bar.

ACCURACY AND RANGE OF THE METHOD

Unless one has had actual experience with this method of rendering displacements accessible to measurement, it is difficult to believe the accuracy attainable when proper precautions are taken. Thousands of observations have convinced me that the method is the most reliable yet devised for the measurement of thermal

FIG. 1 & 2. DIAGRAM OF STRETCHED WIRE DILATOMETER

expansions. I have used the arrangement of Fig. 2 in an oil bath maintained at any desired temperature from near -150°C. up to $+350^{\circ}\text{C.}$, and I have used the arrangement of Fig. 1 in an electric furnace at various temperatures up to about 650°C. I have not personally tested the method at temperatures much above 650°C. Sufficiently fine wires of nichrome or other non-oxidizable material strong enough at higher temperatures to sustain the weights of the damping vanes were not obtainable while I was at the Bureau of Standards. Nor were my arrangements completed for an atmosphere within the furnace which would permit the use of tungsten wires. Recently, however, Dr. Souder, who is now in charge of the Expansion Laboratory, informed me that the Bureau had obtained fine enough wires of a nickel-chromium alloy which, even in air, remained sufficiently strong at temperatures up to 1000°C. Tungsten, if protected from oxidation, could probably be used up to 1400°C. or perhaps even higher.²

The stretched wire method of measuring expansions has not yet been tried at temperatures below -150°C. , because suitable temperature baths have not been conveniently available. The pentane which was used for the bath liquid becomes so viscous when cooled to near -150°C. that proper circulation is no longer possible. It would, however, be a simple

¹Expansion measurements by this method were reported to the American Physical Society at the Washington meeting in December, 1911, and at various times since then. (A. W. Gray, "A New Type of Apparatus for Measuring Linear Expansion," *Phys. Rev.*, vol. 34, p. 139, 1912.) The principle of the method was also described in a communication to the Washington Academy of Sciences. ("New Methods for Displacement Measurements and Temperature Uniformity Applied to the Determination of Linear Expansivity," *Journ., Wash. Acad. Sc.*, vol. 2, p. 248, 1912.) See also "Production of Temperature Uniformity in an Electric Furnace," *Bull. Bureau of Standards*, vol. 10, p. 451, 1914; Scientific Paper No. 219.

²Jeffries recently found the eul-cohesive temperature of platinum to lie between 525 and 550°C. This explains why I could not get platinum wire to sustain continuously the weights of even very light damping vanes when the temperature rose much above 600°C. Jeffries found the eul-cohesive temperature of tungsten to be about 1350°C. (Zay Jeffries, "The Amorphous Metal Hypothesis and Eul-cohesive Temperatures," *Journ., Am. Inst. Metals*, vol. 11, pp. 309-323, 1917.)

matter to modify the apparatus so as to use a bath of liquid air; and, with such refrigerating facilities as are available in the Cryogenic Laboratory of Kamerlingh Onnes, the wire method could be used down to the very lowest temperatures producible with the aid of liquefied helium. It is merely a question of sufficient refrigeration and a suitable container for the bath.

The complete equipment which I planned for the Bureau of Standards has never been finished, and consequently has not been described; but some accounts of measurements made with this apparatus at various temperatures ranging from below -140 deg. C. to above 600 deg. C. have recently been published by my former assistants Schad and Hidnert, by Merica and Schad, and by Price and Davidson.³

The data contained in these papers, some of which are presented graphically, illustrate the performance

FIG. 3.
DILATOMETER WITHOUT
HEATING BATH

FIG. 4. SKETCH OF ESSENTIAL
PARTS OF DILATOMETER

of stretched wire expansion apparatus under conditions of ordinary routine tests. The precision is most clearly shown by Schad's and Hidnert's measurements of the expansivity of molybdenum. They found that all their length observations made at temperatures ranging from -142.5 deg. to $+18.7$ deg. C. were expressible by a quadratic equation with such precision that the probable error of a single observation was ± 2.6 microns per

meter. Likewise, the probable error of a single observation on heating from 18.7 to 305.3 deg. C. was found to be ± 2.5 microns per meter. Since the specimen tested was only 20 cm. long, these values indicate that the probable error in making a single expansion measurement was about ± 0.5 micron. Moreover, a second set of observations from room temperature to 304 deg. C., taken several days later, yielded an equation which agreed so closely with that obtained during the first test that the lengths determined from the two equations did not differ by more than 4 microns per meter, or 0.8 micron in the length actually measured. Some of the slight differences observable between heating and cooling curves, and between curves obtained from different tests of the same specimen, are due to the fact that no solid has yet been found which assumes exactly the same dimensions every time it is brought to the same temperature. Molybdenum repeats better than most substances, and is, therefore, well suited for expansion apparatus is also well illustrated by the is useful not only for adjusting observations, but also be seen by examining the deviation curves published by Merica and Schad.⁴

SIMPLE STRETCHED WIRE DILATOMETER

While the equipment developed at the Bureau of Standards is very efficient for the accurate investigation of thermal expansivity over a wide temperature range, it is more elaborate than is necessary for most scientific or industrial purposes. A simple but reliable dilatometer which the writer made from material to be found in almost any physical laboratory may therefore be of sufficient interest to warrant a more detailed description than that already published.⁵ The apparatus, which uses the stretched wire method of measuring linear displacements, could easily be adapted for commercial testing. It differs from the precision apparatus at the Bureau of Standards mainly in the substitution of an ordinary Brown & Sharpe micrometer screw for the expensive microscope comparator and reference bar. Fig. 3 is a photograph of the dilatometer without the oil-bath for heating the specimen under test. Fig. 4 is a somewhat diagrammatic vertical projection partly in section. Minor constructional details are not represented in order that the essentials may stand out more clearly.

DETAILED DESCRIPTION OF SIMPLIFIED APPARATUS

Extending vertically downward from the cover A of the temperature bath made of asbestos wood are two tubes B and C, the axes of which are separated by approximately the length of the specimen D. At the

³In specifying the accuracy of the method, Merica and Schad (*Journ., Am. Inst. Metals*, vol. 11, 1917, p. 399; *Bull. Bur. Stand.*, vol. 14, 1918, p. 577) state: "The length changes measured in this way are accurate to about ± 0.001 mm. when on a specimen of 300 mm. long (the standard length of the specimen) would be ± 0.0003 per cent." The last part of this statement, however, is misleading, because percentage accuracy in expansion measurements should be expressed as a certain per cent not of the length of the specimen, but of the elongation measured. This will depend not only upon the accuracy of the apparatus and upon the length of the specimen, but also upon the expansivity of the latter and upon the temperature range employed. Since apparatus using a given method of determining thermal expansivity can usually be constructed to accommodate specimens of any convenient length, the essential elements that should enter into a description of the accuracy obtainable by a particular type of apparatus are absolute accuracy in the measurement of elongations and absolute accuracy in the production and the determination of uniform temperatures.

Metals*, vol. 11, pp. 396-407, 1917; *Bull. Bur. Standards*, vol. 14, pp. 571-590, 1918. W. B. Price and Philip Davidson: "Physical Tests on Common High Brass Taken Parallel and at Right Angles to the Direction of Rolling-Appendix," *Trans., Am. Inst. Metals*, vol. 10, 1916.

The expansion determinations reported by Price and Davidson were planned in detail by the present writer; the measurements and charts were made by Messrs. Schad and Hidnert; the specimens of brass were furnished by Mr. Price.

lower end of each tube are two pointed co-axial screws *E* for clamping *D* from opposite sides. One of the tubes, *B*, is rigidly attached to the cover *A*; the other, *C*, is hinged at *F* so as to permit free expansion of the specimen. Fine wires, *G* and *H*, of annealed tungsten, clamped to the lower ends of the tubes by means of the screws *J* and *AK*, extend vertically upward through the tubes and the cover for several decimeters above the latter, where they pass over pulleys and support weights *AA* and *AB*, which keep them tight and straight. The pins *AC* and *AD* cause the wires to bear firmly against the rounded ends of the specimen *D*. Small circumferential V-grooves in these pins center the wires and prevent them from slipping across the ends of the specimen.

At the upper end of the apparatus are two smooth round pins *AE* and *AF*, which bear against the wires *G* and *H*, a decimeter or so below the pulleys. By means of the screws *AG* and *AH* these pins move horizontally in the plane of the wires, so that the upper portions of these wires can be brought closer together or separated a measured distance.

Just above the cover of the temperature bath is placed a horizontal bar *AJ*, of low and known thermal expansivity, protected as far as possible from temperature changes accompanying warming and cooling of the bath below.

This bath, which is not shown in the illustrations, is of oil, heated electrically, and continuously stirred by a screw propeller, the containing tank being provided with suitable guides for insuring thorough mixing and circulation. If air is excluded to prevent flashing, "Renown" engine oil can be used to over 300 deg. C. Pentane gasoline remains sufficiently fluid down to about -150 deg. C. Although these two liquids will cover the entire range, kerosene is usually the most convenient substance when measurements do not have to be extended much beyond either 0 deg. or 75 deg.

After the specimen has been placed in the heating bath and temperature equilibrium has been reached, the upper end of each stretched wire is moved until the wire just touches the end of the bar *AJ*. Contact is indicated electrically by means of an inexpensive reflecting galvanometer in series with a dry cell and a suitable resistance. As the specimen *D* expands, it moves the wires away from the contact bar *AJ*. The magnitude of the expansion is determined from the movements of the screws *AG* and *AH* required to restore contact.

Only one graduated screw is actually used. The ordinary screw *AG*, of moderately fine pitch, moves a horizontal bar *BK*, to which are rigidly attached both the pin *AE*, which communicates the motion to the left-hand wire *G*, and the nut of the graduated screw *AH*, which moves the right-hand wire *H*. In this way a single micrometer screw is made to measure the total displacement of both wires. A Brown & Sharpe micrometer head is convenient for this purpose.

The movement of the bar *BK* is guided without lost motion by means of the thin flat strips of spring metal *BA* and *BE*, which suspend it from the bar *BC*. The smaller bar *BD*, which carries the pin *AF*, is likewise supported by the flexible strips *BE* and *BF* so that it is freely movable horizontally within a rectangular cavity cut through the central portion of *BK*. The spiral spring *BG* surrounding the rod *BH* presses *BD*

firmly against the end of the measuring screw *AH*. The steel ball *BJ*, pressed tightly into the end of *BD*, makes an excellent bearing for the end of the screw.

The bar *AJ* is merely a piece of Pyrex glass tubing. (Fused quartz, because of its still smaller thermal expansivity, would be better.) Bearing firmly against each end of the tube, a tungsten wire (*CK* and *CA*) about 0.1 mm. in diameter is tightly stretched horizontally between two posts, one of which serves to connect the wire electrically with the galvanometer for detecting contact with the adjacent vertically stretched measuring wire. These posts, which may be ordinary machine screws with nuts, are not represented in Fig. 4, but are visible in Fig. 3. The ends of the tube are, of course, suitably ground so that the horizontal wires will be parallel to each other, and so that there will be no interference with the motions of the vertical wires. The horizontal wires define the effective length of the contact bar *AJ*.

PREPARATION OF SPECIMENS FOR TESTING

The preparation of a specimen for an expansivity determination is an easy matter. All that is necessary is to cut off a rod of the required length and to round the ends smoothly, so that they form portions of a cylindrical surface. The rounding should, however, be accurately done, since its purpose is to prevent small angular displacements in the plane of the wires, causing errors by changing the distance between contacts. The easiest and best way of producing the cylindrical surfaces is by grinding.

Fig. 5 illustrates a simple tool for holding a specimen during this operation. By means of radial screws near each end the rod is firmly clamped within a metal tube. Midway between its ends this tube is pivoted between two co-axial pointed screws which hold it with-

FIG. 5. FIXTURE FOR GRINDING TEST SPECIMEN

in the arms of a forked bar of rectangular cross-section. As the bar is gradually advanced toward the edge of the grinding wheel, the tube containing the specimen is rotated between the pivot screws of the fork.

A screw-operated slide-rest is not at all necessary for feeding the specimen toward the grinding wheel. With the exercise of a little care the movement can be sufficiently well guided by pressing one corner of the forked bar into the dihedral angle of a support formed by fastening a straight strip of wood or metal upon a flat surface. The bar is advanced toward the wheel by gentle tapping against the farther end. Even glass can be ground in this way without difficulty.

Near each end of the tube which holds the specimen during grinding are two small holes, one from each side. These form convenient guides for drilling the little conical depressions or holes (*CB*, Fig. 4) that receive the pointed ends of the clamping screws *E*.

SOURCES OF ERROR

The accuracy of the simple dilatometer described

above is limited mainly by the accuracy with which contact can be detected between the stretched wires and the bar *AJ* above the temperature bath. Immediately before taking a series of readings the contact surfaces of both the wires and the bar should be washed with a little ether applied by means of a camel's hair brush. With delicate touch the left-hand screw *AG* is then cautiously and steadily turned until the galvanometer gives the first slight indication of contact between the wire *G* and the end of the contact bar *AJ*. A small deflection that increases with continued advance of the screw indicates a better contact than a sudden, large deflection. After contact has been established with the left-hand wire, the measuring screw *AH* is advanced until the right-hand wire *H* makes contact with *AJ*. At each temperature or measurement, settings of both screws should be repeated a sufficient number of times to make sure that good contacts are being obtained. Failure to obtain a series of concordant readings is evidence that something is wrong—probably a dirty contact or lack of care in turning one of the screws.

The effect of errors in the measuring screw varies inversely as the ratio of the distances from the contact bar *AJ* to the pins *AE* and *AF* for moving the wires and to the specimen *D*. In the apparatus actually used these pins were 600 mm. above and the specimen 150 mm. below the bar, so that the micrometer screw *AH* measured four times the expansion of the specimen. The results showed that with proper use deviations of individual screw readings from the average should not exceed 5 microns. The average deviation of 107 individual readings from the average reading for each temperature was less than 2 microns, corresponding to an average deviation of 0.5 micron in determining the expansion of the specimen.

Corrections must be applied on account of length changes in *AJ* and in *BK* brought about by temperature changes occurring in these bars during the course of an expansivity determination. With a dilatometer in which the wires multiply the elongations by 4, the apparent expansion of the specimen must be corrected by the expansion of *AJ* and $\frac{1}{4}$ the expansion of *BK*. Although it is easy to calculate these corrections if the expansivities and the temperatures of *AJ* and *BK* are known, it is more convenient to render the corrections negligible, or at least very small, both by using materials of low expansivity for these parts of the apparatus and by protecting them from temperature changes—especially changes caused by convection, conduction and radiation from the bath for heating the specimen under test.

CONCRETE ILLUSTRATION OF AN EXPANSIVE DETERMINATION

A concrete example illustrating the capabilities of the above-described simple apparatus is afforded by a determination of the thermal expansivity of some optical glass.^a

A summary of the measurements made is contained in the accompanying table. In this table Column A gives in degrees Centigrade the temperatures of the oil bath in which the specimen was heated. These tem-

peratures were determined by means of the platinum resistance thermometer visible in Fig. 3. The mercurial thermometer also shown was used merely as a rough indicator. Column B gives in microns the expansion of the specimen observed on heating it from 23.45 deg. to each temperature recorded in Column A. In obtaining these values the corrections given in Column D were added to the apparent expansions indicated by the measuring screw. For calculating the corrections the linear expansivities of the brass bar *BK* and of the Pyrex glass tube *AJ* were assumed to be 0.000018 and 0.0000032 per degree Centigrade, respectively. The magnitudes of these corrections could have been greatly reduced by proper choice of materials together with proper thermal insulation.

The precision attained in measuring the expansions is indicated by Column C, which gives opposite each temperature the average deviation in microns of the

FIG. 6. THERMAL EXPANSION OF OPTICAL GLASS

individual indications of the measuring screw from the average value observed at that temperature. The deviations here recorded, which correspond to elongation of the specimen under measurement, were obtained by dividing the corresponding deviations of the actual screw readings by 4, since the stretched wires multiplied the specimen elongations by 4. Column E shows the number of micrometer screw observations that were averaged at each temperature to obtain the values under B and C. Examination of the table shows that, for the 107 contact observations represented, the average deviation was only about 0.46 micron. This gives some idea of the high precision attainable with a stretched wire dilatometer even when the construction is as crude as that pictured in Fig. 3, which is a photograph of the apparatus actually used for obtaining these results.

THERMAL EXPANSION OF OPTICAL GLASS

A	B	C	D	E

A plot representing the observations recorded in the table is shown in Fig. 6. The straight line corre-

^aAt the request of Dr. Arthur L. Day, Optical Glass Committee, War Industries Board, the writer undertook to determine the expansivity of this glass, which had been produced under the direction of the former for naval searchlight mirrors. The dilatometer pictured in Fig. 3 was hastily designed and constructed especially for this work.

sponds to an expansivity of 0.00000794 per degree Centigrade. The last two observations, which were made the day following the observation near 308 deg., are represented by the open circles. Such failure of a glass to return to its original length upon cooling after strong heating is frequently observed.

Although Fig. 6 indicates an accuracy sufficient for most scientific or industrial purposes, it should be borne in mind that the specimen tested was only 60 mm. long and that the corrections given in Column D of the table are both considerably larger and considerably more uncertain than need be. If the errors involved in the corrections be rendered negligible by the means indicated above, the relative accuracy of the expansion measurements will be increased in the same ratio as the length of the specimen under test is increased, since the deviations in Column C represent absolute, not relative, precision in length measurement.

VARIATIONS OF THE STRETCHED WIRE DILATOMETER

The apparatus actually constructed as outlined above illustrates merely one particular arrangement for applying the general principles of the stretched wire method. It was hastily designed and built to meet an emergency.

Various details could obviously be modified. For example, two independent graduated screws for moving the stretched wires *G* and *H* would be a convenience; any sensitive detector of contact is usable; tungsten wires are not necessary, etc. Moreover, micrometer screws can be arranged to replace microscopes for use with either an air bath (as in an electric furnace) or a liquid bath; so that the range of application even in the simplified form of dilatometer is not limited to the interval between room temperature and 300 deg. C.

Nor is the application of the stretched wire method limited to the case of thermal expansion. The writer has already used wires for measuring magnetostriction in nickel steels at temperatures ranging from -75 deg. to +300 deg. C.¹ Wires could easily be adapted to the construction of an extensometer for measuring deformations of materials during any kind of testing, especially when it was desired to control the temperature of the test piece. In fact, there appears to be no other method that is quite so reliable for accurately following linear displacements that occur in regions which are difficult of access.

The Magnesite Industry in Austria

THOUGH the term "magnesite" is generally applied to the iron-bearing carbonate of magnesium, such is found in Austria and Hungary, by some Austrian magnesite is referred to as bruennerite. The mineral bruennerite has become of commercial importance only in Austria. The important deposits are found in Styria, lower Austria and northern Hungary. The mineral occurs at Eisenerz, Styria, while the world's largest deposit of spathic iron ore, or iron carbonate (FeCO_3), occurs at Eisenerz, Styria, while the world's largest deposit of spathic bruennerite is found at Veitsch, in the same province.

The Styrian and lower Austrian deposits are located much nearer the Adriatic Sea than are the deposits of northern Hungary; and it is from the former that most of the exported magnesite has come. They are located southwest of Vienna, and extend west from Semmering through the Murz Valley to Tyrol. The chief deposits reckoning from east to west are those of Semmering, Veitsch, Breitenau, Trieben, Radenthein and Dienten.

The largest and most important deposit is that at Veitsch, located near Mitterdorf, on the South Austrian Railroad in the Murz Valley, Styria. Here the magnesite, which occurs in the form of a lens, is quarried on the slope of a hill in a series of terraces about 50 ft. apart. The entire work extends through a vertical distance of 500 ft. The huge magnesite lens is nearly $\frac{1}{2}$ of a mile long and over 1000 ft. in width, and probably extends to a considerable depth.

The formation containing the magnesite extends where magnesite is quarried beyond Jolsva and Nyustya, in the Gomer district. In spite of the remote location of these deposits as compared with those in Styria, magnesite was shipped from them before the war a distance of 360 mi. to the port of Fiume for overseas shipments to other parts of Europe and to America.

The average analysis showing the composition of the mineral found in Austria-Hungary is as follows:

	Per Cent	Per Cent
Magnesite.....	33 to 44 Silica.....	1 to 5
Lime.....	1 to 3 Carbon dioxide.....	50
Ferrous oxide and alumina.....	2 to 7 Water.....	

CHARACTER OF THE SINTERED PRODUCT

The magnesite occurs as lenticular masses in a belt of carboniferous rocks consisting mainly of metamorphosed shales, sandstones, conglomerates and limestone. It is grayish in color when fresh, and contains sufficient ferrous carbonate to blacken it when calcined. It turns brown owing to the oxidation of the ferrous carbonate when exposed to the air. The quantity of carbonate of iron is variable and different analyses show that it ranges up to 13 or 14 per cent.

For the most part, only the sintered article has been imported into the United States. This material has achieved an enviable reputation for its uniformity both as to chemical and physical characteristics. The homogeneity of the sintered Austrian magnesite is doubtless due in part to the averaging effect of the different operations, such as crushing, dressing, sintering and mixing, an effect which is not obtainable in mere hand samples.

There is comparatively little variability in the sintered magnesite as marketed, and five analyses of this sintered magnesite as quoted by Cornu¹ are as follows:

	Per Cent
Magnesite (MgO).....	85 53 to 90 07
Lime (CaO).....	0 96 to 3 32
Ferrous oxide (Fe_2O_3).....	7 43 to 9 96
Alumina (Al_2O_3).....	0 00 to 2 22
Manganese oxide (Mn_2O_3).....	0 51 to 0 76
Silica (SiO_2).....	0 26 to 1 34

QUARRYING AND PREPARATION

The methods of quarrying and preparing magnesite

¹F. Cornu, *Z. Prakt. Geol.*, 1908.

²A. W. Gray, D. H. Sweet and L. W. Schad: "Some Effects of Magnetization on the Length of a 35.25 Per Cent Nickel Steel," *Phys. Rev.*, vol. 7, p. 684, 1916.

in Austria and Hungary are similar at most of the different plants. On the outskirts of the village of Veitsch, about 56 mi. southwest of Vienna, is found one of the largest deposits, and one which has been worked the longest. Since the methods of mining and preparation here are fairly typical, they will be outlined.

As stated above, the magnesite quarry at Veitsch is worked in a series of steps or levels about 50 ft. apart vertically. The material is blasted out of the solid by the ordinary methods of rock quarrying. It is next broken in pieces which can be handled readily by one man, and the dolomite and quartz are carefully picked out. Even in the best of the deposit, there is a large quantity of this gangue material, and estimates of the waste rock vary from 50 to 66% per cent of all the material quarried. Terrace quarrying and working conditions in general like these at Veitsch are practiced at Breitenau and at Eichberg.

The coarse quarried material is cobbled to free it as far as possible from impurities like chist, dolomite and quartz, and the lumps are sorted. The cleaner portions of the magnesite are reduced to pieces about the size of a man's head. Less pure portions have to be broken into pieces about the size of a man's fist. These dressing operations involve a considerable loss of magnesite in the form of small fragments, too small to be burned in shaft kilns. The raw material thus obtained in the quarries at Veitsch is transported by gravity planes to the sintering kilns at the foot of the hill.

SINTERING TEMPERATURE

According to Morganroth,² continuous kilns of the bottle variety are used and producer gas is employed as fuel. These kilns burn on an average of 15 to 24 tons of calcines per 24-hr. day. Within the last few years, a few plants have installed rotary kilns of the cement type to burn the magnesite, powdered coal being used as fuel. The capacity of these kilns is 50 to 60 tons per 24-hr. The magnesite can be burned as thoroughly in these kilns as in the bottle kilns, but they have one disadvantage in that a larger per cent of fines is produced. The magnesite as burned in the bottle kiln is drawn every 6 hours.

The sintering temperature varies from 1500 deg. C. (2350 deg. F.) for bruennerte containing considerable iron oxide to 1700 deg. C. (3100 deg. F.) for material poor in iron oxide. However easily the material sinters, it appears desirable to carry the temperature up to at least 1500 deg. C. (2700 deg. F.), but this temperature seems to be exceeded, as a rule, in the shaft kilns in Styria.

TREATMENT OF THE CRUSHED SINTER

The magnesite, after being drawn from the kilns, is quenched with water and crushed to walnut size or less. It is then classified mechanically by screening or sizing into three different sizes. Much of the caustic lime or calcined dolomite is removed in the first screening owing to its finely divided condition. From the screens it goes to the picking tables, where the underburned magnesite, together with the dolo-

mite and quartz, present in particles too small to have been removed at the quarries, is picked out. These are light colored, and consequently readily distinguishable. The magnesite in the larger sizes is again crushed and the smaller pieces repicked. The magnesite is finally crushed to the size of kernels of corn, picked over again, and sacked for the trade in packages of 150 to 200 lb. each.

In recent years, magnetic separators have been introduced which have resulted in an economy in the picking or sorting operation. If not magnetically treated, the finely divided material marketed would necessarily contain particles of schist, quartz or other non-magnetic minerals. It must be said, however, that the magnetic treatment involves some waste, since only magnesite containing iron is removable by this treatment. It adds to the expense and is presumably employed only when it is necessary to obtain a concentrated, uniform and most highly refractory product.

In addition to the milling and sintering plant at Veitsch, where operations are as outlined above, there are other localities in Styria where work is done in a similar manner, for example at Breitenau, Trieben and in lower Austria at Eichberg, near Gloggnitz.

FUEL REQUIRED

The amount of fuel required to sinter Austrian magnesite varies and is dependent in part on the quantity of the ferrous carbonate present. With good flaring brown coal, having a heating value of 6000 calories, the quantity required varies from 600 to 800 lb. per ton of sintered magnesite. The fuel requirement has been estimated by others at 1000 lb. per ton of sintered magnesite produced. The latter coal, however, has a calorific value of only 4000.

The abundance and accessibility of the brown coal used in sintering Austrian magnesite has been a very important factor in the cheapness of past production.

OTHER COMMERCIAL CONDITIONS

At Veitsch the marketable sinter is trammed on an aerial tramway about 4 mi. long to Wartberg Station. The works at Trieben are near the station, which is located about 3 mi. from the deposit at Sunk, where the material is quarried. At Pradenthein, work was begun by American capital in 1908, and from that time till the war cut off the supply a great deal was shipped to Philadelphia, New Orleans and New York. The shipments from Europe were usually made through the port of Trieste, and before the war ocean freight per ton was \$2.50.

The facts that the Austrian deposits are large and are easily quarried; that they are within easy reach of transportation facilities, and the additional fact that labor, at least before the war, was cheap have all tended to give Austrian magnesite commercial supremacy in the world's markets. These conditions, moreover, help to explain the success which Austrian magnesite has achieved in the past and indicate the possibility of the competition which it may be able to exert in the future. Only the massive deposits of the Veitsch type can be quarried and worked at a profit, however, and some of the larger deposits, not well located, have been unable to compete in the past.

²Bulletin, American Institute of Mining Engineers, No. 93, 1914, pp. 2345-2452.

Melting of Some Non-Ferrous Metals and Their Alloys in Electric Furnace

Requirements for Economic Melting of Non-Ferrous Metals and Their Alloys—Adaptability of a Contact Arc Resistance Type Furnace—Melting Cost in Electric vs. Fuel-Fired Furnaces—Sources of Losses—Tabulated Data

By E. F. COLLINS

SATISFACTORY and economical melting of non-ferrous metals and alloys requires a furnace of the following specifications:

Dependability and continuity of operation.

Freedom from oxidation of metals or alloys while in the furnace; in fact, deoxidation of metals or alloys in some degree is usually advantageous.

Freedom from volatilization of metals should exist subsequent to their liquefaction and while in the molten state, to prevent loss of metal in the form of escaping vapor, which usually oxidizes upon its escape from furnace to air, when the furnace atmosphere is neutral or reducing, i.e., free from oxygen.

FREEDOM FROM SLAGS

The slags, which are due to overheated linings, dirt from scrap, oxides from metals, etc., should not mix with the melted metal. This allows of dry skimming (during melting) of dirt, sand and other impurities, without entrained metal in the form of shot in the fused slag, that must subsequently be crushed and the metal reclaimed by more or less elaborate process. The furnace should not require the maintenance of an elaborate and expensive reclaiming plant. In other words, impurities should float on top of the bath in the furnace and allow of skimming this from the surface of the bath. It should allow of the use of sal ammoniac or other flux to aid in cleaning the metal while molten in the furnace, but should not regularly require the use of such flux to give perfect metal; neither should the bath require charcoal covering while melting or subsequently while held in furnace.

Uniformity of alloy and absence of segregation should exist when the furnace charge has reached the pouring stage, i.e., test bars should show uniform physical characteristics throughout their length, a perfect fracture, satisfactory crystallization and lack of segregation under microscopic examination.

MELTING CHAMBERS AND THEIR SIZE

The furnace linings and atmosphere must be free from the slightest degree of sulphur, and the furnace atmosphere must be controllable as regards oxygen when melting copper and many alloys rich in copper, in order to produce satisfactory foundry castings of sound metal, since copper greedily absorbs sulphur and oxygen when hot, which gives rise to trouble on cooling. In fact, furnace melting chambers should be free from contaminating influences, coupled with a controllable atmosphere with respect to oxygen, in which case electrolytic cathodes, free from salts of the electrolytic bath, may be melted down and poured "at pitch" without "rabbling and poling." This will eliminate the use of the present day reverberatory copper refining furnace and allow of making brass directly from cathode copper as well as

cathode zinc, thus saving one refining operation on copper and one melting or "pigging" operation on zinc.

The melting chamber should be arranged so that its atmosphere may be reducing, neutral or oxidizing for certain metals and alloys, i.e., its oxygen should be controlled. A certain flow of gas through the furnace may be required at times and at others a "dead" or "still" atmosphere is absolutely necessary. No advantage, however, is secured in attempting to seal hermetically the furnace unless some process of distillation is attempted. Hence, if the furnace is provided with doors, it is only necessary that they close in such a manner, and are of such construction, as to prevent an undue loss of heat and circulation of gases in the furnace when they are closed. A single small opening in the furnace, such as is required for stirring the bath or pouring, may produce a sort of breathing of the furnace when the vent is open, but the loss of heat or metal is not appreciable if the furnace is being properly manipulated.

Large-capacity furnaces which do not involve the use and handling of crucibles are desirable where local conditions will permit. Large furnaces promote economy, due to higher thermal efficiency, saving floor space in proportion to metal melted, saving in labor, saving in cost of lining per ton of metal melted, especially when compared to crucible cost, their storage, drying and tempering, spill from broken crucibles, etc.

Where metal is melted in large furnaces, preheated hand ladles or crucibles are used to transfer the molten metal to molds where small foundry castings are being made, and it is important that these ladles or crucibles be well and properly preheated before using, especially when pouring small parts such as $\frac{1}{2}$ -in. brass valves, etc., in order to get satisfactory work. The burden of the preheated crucible is eliminated several times over by the many advantages coupled with the use of the non-crucible tilting furnace above ordinary crucible capacities.

FURNACE LININGS

Furnace linings should in the main be built of commercial refractories of moderate cost, which are at all times available, such as standard fire brick and shapes, with limited use of special refractories where the results justify their usage, rather than of special refractories, which can be procured only at high price and with more or less difficulty and uncertainty. If the foundryman or metal melter will make repairs upon his linings at least once every two weeks, and when in severe service once each week, his lining cost will be much less than when special high priced refractories are used and repairs and inspection of linings are less frequent. The refractoriness of linings should be such that they will not fuse or slag perceptibly at melting temperatures. Their inner surface should be glazed over at tempera-

tures above the metal melting zone. This guards against slag formation during the melting process, assuming that no chemical reaction occurs between metal and hearth to reduce the fusion point of the refractories. As an illustration, the presence of lead in brass melting fluxes the refractories at temperatures at which they are immune in contact with the same bath free from lead.

HEAT DISTRIBUTION

Shallow baths promote a more uniform and rapid melting and freedom from segregation than the deep bath. The source of heat should be a uniform, mild, "soaking" heat, and its temperature gradient above the bath should be moderate; that is, due to a large absorbing surface, the bath takes in a large quantity of heat at a low heat potential. The transfer of heat to the metal is accomplished most successfully by radiation to the top of the bath and conduction to the bottom. In case the source of heat is only slightly higher than the charge when the fusing point of metal is reached, the metal may be held for an indefinite period within that zone of temperature above the fusing point in which vapor tensions are not sufficiently high to cause appreciable loss of metal from volatilization. In other words, if the source of heat is such that its temperature lies in the temperature zone safely below the destructive distillation point of the metal, then the bath can in no manner exceed it. A safe way in securing this heat control is to limit the temperature of the heat source by means of a pyrometer. Pyrometers are available at present which live for a satisfactory period in certain brass furnaces, which makes their use entirely practical. It follows from the above that furnace design should be such as to allow of the source of heat being held at any temperature desired.

The heat distribution should be fixed and if possible automatically controlled; i.e., heat received by radiation as related to that received by conduction should be such as to secure a uniform heat of the bath. If any variation in the ratio of heat radiated to top of the bath and that conducted to bottom is permissible, this variation should allow of a reduction of radiant heat at the top of the bath at once when the fusing temperature is reached, because when the bath is liquid its bottom convected heat will give uniformity of temperature to the bath.

The foregoing sets forth more or less in detail the requirements for economy in melting brass alloys. It is now desired to consider the characteristics of the electric furnace and see how completely it overcomes the obstacles met with in the fuel-fired furnaces for melting non-ferrous metals and their alloys.

CLASSIFICATION OF ELECTRIC FURNACES

Class I comprises furnaces in which heat is developed by the passage of current through a solid, laminated or granular conducting medium or resistor.

(A). The conducting medium may consist of material that is to be treated.

(B). The heat developed in the "resistor" is transferred to the charge by conduction or radiation or both; a wall may or may not intervene between the "resistor" and the charge.

(C). A readily controllable amount of heat is generated between a fixed and movable carbon electrode, their distance apart being maintained such that the granular carbon lying between the faces gives rise to many chains

of series and multiple contact or resistance arcs, enveloping adjacent electrode faces.

Class II comprises furnaces in which heat is developed by the flow of current through a liquid or solid conductor.

(A). Electrolytic.

(B). Non-electrolytic.

Class III comprises furnaces in which heat is developed by flow of current through gas or air arc furnaces.

In the making of brass, furnaces lying in each of the three classes have been tried out. Furnaces lying in Classes I and II lend themselves readily to the generation and control of a mild, "soaking" heat such as is required for melting volatile alloys. As illustration, the common resistance furnace lies in Class I, and the induction furnace in Class II. Furnaces in Class III generate a too intense and burning heat to be used with even questionable success in melting volatile alloys without the use of much unnecessary manipulation and watchfulness requiring much skill. Control of the electric arcs in atmospheres high or low in volatile gases, freedom from surging, low power factor and high metal loss are some of the serious problems confronting the man who would melt volatile alloys in the Class III arc furnace. Their employment had best be left for steel.

ADAPTABILITY OF TYPE C RESISTANCE FURNACE

A furnace falling in Class I and Type C of the above classification has proved, upon experience gained from many tests as well as from its commercial operation in the foundry, that it is the best adapted for melting non-ferrous metals and their alloys.

Its design, construction and the reasons why it is suited to melting the non-ferrous metals and their alloys are given below somewhat in detail.

DESCRIPTION AND DESIGN OF FURNACE

An example of this type of furnace is shown in Figs. 1 and 2. It will be noticed that it consists essentially of a refractory lined case within which are located in the same chamber the heating units lying on either side of the melting hearth (3). The source of heat is 13 and lies in a duct separated from the bath by carborundum walls 5 and 6. This duct is fitted with cross electrodes 9 and with wearing blocks 12 under each of two vertical electrodes projecting through the arched roof. These cross electrodes in the bottom of the duct, as well as the wearing blocks between them and the vertical electrodes, are of carbon. The whole duct is filled with granular soke to the height of the bridge wall 5 and 6 on either side of the hearth. Neutral electrodes 16 and 17 make contact with the cross electrodes 8 and 9. These neutral electrodes are for the sake of automatic control, as will be seen later. The vertical electrode carries a water-cooled ring where it emerges from the top arch. The cable clamp for electrode 15 is also water-cooled. The two vertical electrodes 11 are terminals of one phase, while those marked 10 are terminals of another. In other words, the furnace is inherently 2-phase. By multiplying the 2-phase, however, it may be operated single phase, or by using Scott transformer connections it may operate from 3-phase source. The phase voltage most satisfactory has been found to be 60 to 70 v. The detailed arrangement of the electrodes, etc., in resistor duct is evident.

The operation of the furnace in generating heat is as follows:

The current supplied to the furnace flows through the vertical electrodes 10 and 11 through a short space filled with granular carbon to the wearing block 12, into the cross electrodes 9, into second wearing block 12' and out to line through second granular coke strata and second vertical electrode. The value of the current is regulated automatically by varying the distance between the vertical electrodes and the wearing block. In other words, by means of a current-controlled relay the distance between 11' and 12' is governed; also by means of a voltage-controlled relay connected to neutral bottom

FIG. 1. SCHEMATIC VIEW CONTACT ARC RESISTANCE TYPE FURNACE

electrodes and vertical electrode 11. The distance between electrode 11 and wearing block 12 is held to correspond to one-half the phase voltage, i.e., 30 to 40 volts. A rheostat on the control panel allows of setting control for any current value required, and when once set for a given value, such value is held until the rheostat position is changed by the furnace operator. Hence the power input is automatically held constant and is

FIG. 2. SECTION OF CONTACT ARC RESISTANCE TYPE FURNACE

subdivided equally between the vertical electrodes. Starting with a cold furnace the heat is generated first in the granular carbon separator lying under the bottom face of the vertical electrode. This immediately becomes

incandescence by virtue of the current carried by the carbon granules, and heat is also generated by a multitude of contact arcs enveloping the lower end of the vertical electrode. Heat is at once taken from this source by the granular coke in the trench and its whole surface becomes heated to the desired point. The surface of the granular carbon radiates heat to the arched roof, and the body of granular carbon and wearing block with the cross electrodes conduct heat to the furnace walls and to the sides and bottom of the hearth with which they are in contact. Furthermore, as the furnace becomes heated a certain amount of current flows from the vertical electrode 11 to vertical electrode 11' directly through the granular coke in a way similar to the simple carbon resistance furnace. This heat may be as much as 30 per cent of that developed locally at each vertical electrode as above described through contact arcs and resistance. This heat is largely radiated to the roof, since it is generated largely in the upper surface of the coke body. In addition to serving as enclosing wall of the furnace, the roof is so shaped that it acts also as a highly efficient reflector, throwing the heat received from the incandescent coke ducts on either side of the hearth uniformly on the hearth or bath. This heat is very uniform and what is called a mild "soaking heat," and

FIG. 3. CHART SHOWING CONTINUITY OF SERVICE OF ELECTRIC FURNACE MELTING BRASS IN

hence lends itself well to the melting of brass or volatile metals; especially is this a fact since a part of the heat is supplied to the bath from the bottom and sides.

SOME CHARACTERISTICS OF THE FURNACE

To enumerate briefly some characteristics of the above-described furnace which makes it essentially suited to melting non-ferrous metals and their alloys, we have the following:

1. The temperature of the heat generating source is controllable at will.
2. The heat generated is of the mild "soaking" type, uniformly distributed, and any workable temperature gradient may be maintained between the charge and the heat source.
3. The heat is received by the charge from above, on the sides and through the bottom.
4. The bath is comparatively shallow and a large surface is exposed to receive the heat. (The bath depth is approximately 6 in. in a 1500-lb. furnace.)
5. The furnace has normally a reducing atmosphere, which may readily be made neutral or oxidizing.
6. Automatic control of power, requiring little attendance.
7. The furnace atmosphere is free from contaminating gases.
8. A "dead atmosphere" practically restrained from escape exists normally in the furnace.

9. The temperature is controllable, so that slags do not form in melting brass. Hence simplicity of metal recovery from the dirt skimmed from the top of the bath in the furnace.

10. The furnace may be "forced," i.e., the heat may be fed to the metal as fast as it is absorbed, and a high rate of melting results with all its advantages and with none of the disadvantages met with in fuel-fired furnaces.

11. Dependability of furnace and continuity of operation under commercial conditions as illustrated in Fig. 3. The delays due to the furnace are of short duration when compared to the time the furnace was delayed due to foundry conditions; in other words, little melting capacity was lost and chargeable to the furnace as compared to that lost due to delays for which the foundry alone was to blame.

Fig. 4 shows a working installation of a furnace of the type described, which has a melting capacity of 1500 lb. of brass per hour. The most recent design of this type of 1500-lb. furnace is shown in Fig. 5.

INDUCTION FURNACE VS. RESISTANCE FURNACE

The induction furnace is said to be exceptionally efficient thermally while melting. Its overall working efficiency for the week is not appreciably different from that of the resistance furnace; but it is desired to call attention to the fact that kw.-hr. per ton consumed in melting may by no means indicate the highest overall working efficiency.

Suppose, for illustration, we concede that the induction type of furnace has the highest thermal efficiency in melting. A certain furnace of this type has a crucible capacity of 400 lb. and a load loss or radiation of 8 kw.-hr. per hr. and melts a charge of red brass each hour. Suppose the charge is poured at 1300 deg. C.; it is necessary to use hand ladles preheated in pouring the charge. The furnace must be kept hot 24 hr. per day

FIG. 4. 1500-LB. 300-KW. BRASS-MELTING FURNACE

when the crucible has once been heated up. Let us now compare the effective working kw.-hr. consumption per ton with that of a 2250-lb.-per-hour tilting type resistance furnace of the design described and melting 18,000 lb. of red brass per 8-hr. day. It will be noted that this furnace may be charged by machine, whereas the crucible furnace must be carefully charged by hand. The pouring of the charge will be by hand with preheated ladle, and should cost the same as pouring a like quantity of metal from crucibles.

It seems, since five to six 400-lb. crucible furnaces must be employed to give the same metal output as one 2250-lb. tilting furnace, that labor of attendance charging and melting per ton should cost at least $2\frac{1}{2}$ times as

FIG. 5. CLASS I, TYPE C, BRASS-MELTING FURNACE, CONTACT ARC RESISTANCE TYPE

much in a crucible furnace as in a tilting hearth type. Hence, it follows from the above:

Metal melted per week in 400-lb. crucible induction furnace 8-hr. working day	$48 \times 400 = 19,200$ lb.
Kw.-hr. to melt 19,200 lb. at 200 kw.-hr. per ton	$200 \times 96 = 19,200$ kw.-hr.
Kw.-hr. to keep furnace hot while not melting ($24 \times 7 = 168$), $168 - 48 = 120$ hr. per week	$120 \times 8 = 960$
Total kw.-hr. per week	2,880
Kw.-hr. per ton	$2,880 \div 96 = 300$
Power cost per ton at \$0.01 kw.-hr.	\$3.00
Excess labor cost of 400-lb. crucible furnace over 2250-lb. tilting hearth per ton	1.25
Total	\$4.25

This \$4.25 is the power cost that may be allotted per ton to the 2250-lb. furnace and maintain an equal all-week efficiency for the same total amount of metal melted by either furnace. In other words, if the large tilting furnace melts with the not unexpected consumption of 425 kw.-hr. per ton, it has equaled the performance of the induction crucible furnace, which, offhand, seems much more efficient because we say it melts for 200 kw.-hr. per ton. Large-capacity induction furnaces might change the above somewhat, but the writer does not know of any successful design on the market at present for melting brass in capacity exceeding 600 lb. In fact, these are limited in their use to certain mixtures only. Leaded brass above 3 per cent cannot be successfully handled, due to the fluxing action on crucibles, etc.

The above clearly shows that a furnace should not be selected merely because it melts at a low kw.-hr. per ton, but all its other characteristics should be studied and its overall cost of turning out metal should be considered, when conforming to local conditions, since different working cycles may give widely different overall results.

COST OF ELECTRIC MELTING VS. FUEL-FIRED FURNACES

Attention is called to certain characteristics, losses, handicaps, etc., which influence the overall cost of melting and must be considered in making up true melting costs. These will now be considered and their effect shown upon costs as tabulated in Table I.

This table gives average data by which one may judge correctly as to the general problem of electric vs. fuel-fired furnaces. Results for individual foundries may be readily found by substituting in the itemized costs those which correspond to local conditions. Thus: 1.5c. per

TABLE I—AVERAGE COST OF MELTING BRASS WITH FUEL-FIRED OR ELECTRIC FURNACE

kw.-hr. has been used as electricity or power cost; if this is 1c. in the plant under consideration, this figure should be substituted. Likewise other values may be converted to actual ones for an actual local condition.

melted down and 180 lb. of zinc added at 1100 deg. C. and pouring at 1100 deg. C., with results shown in Table III.

TABLE II—SOURCES OF METAL LOSS IN MELTING

	Electric	Fuel Fired
Temp. control	Excellent	Indifferent
Size of charge	Controllable	Controllable
Gas flow from furnace	Negligible	Large volumes if combustion gases must pass out
Furnace atmosphere	Free from oxygen and injurious gases	Contaminated by impurities of fuel. Protection against oxygen only through excess fuel supply
Chemical condition	Free from oxygen and injurious gases	Contaminated by impurities of fuel. Protection against oxygen only through excess fuel supply
Speed of melting	Much greater than fuel-fired	Much less than electric

It will be noted from Table II that conditions are under absolute control in the case of the electric, whereas in fuel-fired furnaces the control of temperature is indifferent, and large volumes of gases of combustion must pass through the furnace. Likewise, since heat is generated through the oxidation of fuels, the furnace chamber cannot be free from oxidizing and contaminating influences upon the metal.

FIRST SOURCE OF LOSS

Temperature Control. In a given electric furnace, the amount of metal lost in melting increases as the temperature for forming the alloy lies above the melting point of the alloy. Lack of temperature control may increase the metal losses in melting brass, as illustrated by the following tests: First, 70:30 brass is made in the electric furnace, taking 420 lb. of copper and melting down and then adding 180 lb. of zinc, at 1170 deg. C. pouring at 1150 deg. C. Second, 420 lb. of copper was

TABLE III.

Yellow Brass Metals	Temperature of Alloying	Pouring Temperature	Alloy Recovered lb.	Per Cent Zn Loss	Per Cent Metal Loss
(a) { 420 lb. Cu 180 lb. Zn }	{ 1170 deg. C. 2140 deg. F. }	{ 1150 deg. C. 2150 deg. C. }	565	19	5 8
(b) { 420 lb. Cu 180 lb. Zn }	{ 1100 deg. C. 2010 deg. F. }	1100 deg. C.	590	5.6	1 6

The chemical tests corresponding to the above are:

(a) { Cu 70 Zn 30 }	1170 deg. C.	1150 deg. C.	{ Cu 75 9 Zn 24.1 }	24	7 3
(b) { Cu 70 Zn 30 }	1100 deg. C.	1100 deg. C.	{ Cu 71 3 Zn 28 7 }	5.5	1 6

The results in Table III show the effect of temperature on the same metal (yellow brass) and how one may readily control the melting loss in the electric furnace by observing the alloying or pouring temperatures.

SECOND SOURCE OF LOSS

Size of Charge. Pounds metal lost on melting is independent of the charge in a given electric furnace, free from ventilation.

Metal Melted, Lb.	Charge Per Cent of Capacity	Temp. Melt, Deg. C.	Metal Loss, Per Cent
2696	674	70	1 4
3727	932	100	1 4

THIRD SOURCE OF LOSS

Gas Flow From Furnace. In the fuel-fired furnace the magnitude of loss from this source is influenced by the speed of melting, and by the pressure, volume and velocity of the gases flowing over the melting metal. Thus increasing the atmospheric pressure in the furnace and decreasing the volume and velocity of the gases tend to reduce the volatilization loss. For each fuel there is a maximum limit to gas speed or velocity through the

furnace, since each fuel in developing the required heat units to get the heat out at a given speed must develop a certain volume of gases which must pass out. Hence proper gas velocity is inseparably connected with products of combustion results from various fuels. Approximate volume of flue gases averages in coal, coke and

TABLE IV. METAL RECOVERY TEST

(Actual Test on Red Brass)		Per Cent	Type Furnace
Metal Charged	Metal Recovered	Loss	
1 heat, 1500 lb.	1465 lb.	2.33	Electric tilting
1 heat, 1500 lb.	1484 lb.	1.07	Electric tilting
4 heats, 250 lb.	980 lb.	2.00	Coal-fired crucible
4 heats, 250 lb.	990 lb.	.85	Coal-fired crucible

The chemical analysis for melting loss on the same electric furnace, and the same metals, showed approximately 0.4 per cent Zn loss.

Analysis of metal charged	Sn	Pb	Cu	Zn	Fe
	4.30	6.55	80.88	8.02	0.25
Analysis of metal poured (no charcoal)	4.29	6.60	81.46	7.61	0.25

TABLE V. ACTUAL TEST (YELLOW BRASS) ELECTRIC FURNACE

	Metal Charged	Metal Poured	Per Cent Loss
Metal recovery test	600 lb.	590 lb.	1.67
Analysis metal loss	Charged Cu 70 Poured Cu 71.3	Zn 30 Sn 28.6	

TABLE VI. ELECTRIC FURNACE MELTING PHOSPHOR BRONZE

Metal Recovery Test (Actual):			
Metal charged, 2696 lb.	Metal poured at 1100 deg. C.,	2656 lb.	Loss, 1.4%
Metal charged, 3727 lb.	Metal poured at 1200 deg. C.,	3678 lb.	Loss, 1.5%

Physical Test of Metal:

	Electric Furnace	Oil Furnace
Tensile strength	27,900	24,969
Yield point	10,444	9,850
Elastic limit	7,300	7,000
Elongation in 2 in., per cent	19.4	16.9
Elongation in 8 in., per cent	17.2	14.9
Reduction of area, per cent	21.4	19.7

	Crucible Furnace	Electric Furnace
Tensile strength	30,250	30,820
Elastic limit	17,833	18,000
Elongation in 2 in., per cent	16.14	19.57
Reduction of area, per cent	16.10	22.00

oil furnaces from 3350 to 5800 cu.ft. per 100 lb. of metal melted. Hence it is easy to see how the flow of gas may bring about a very large volatile loss in the fuel-fired furnace. In the electric furnace the gas flow is very small, and consequently, though its atmosphere be saturated with metal vapors, so little gas leaves the furnace during the melt that the loss resulting is negligible.

FOURTH SOURCE OF LOSS

Oxidation and Gas Absorption. Copper, zinc, tin and lead, the constituents of commercial brasses, are all very readily oxidizable at the temperatures to which they must be heated for melting and pouring. Oxidizing results in loss of metal and actually burns the metal to a dross. One can readily maintain a neutral or reducing atmosphere in the electric furnace, but it is certain that carbon monoxide must be so high and oxygen so low that one cannot, in ordinary furnaces, hope to maintain a reducing atmosphere without sacrificing many heat units through burning carbon to CO instead of CO₂.

Gas absorption is proportional to the temperature and the time the metal is held in contact with the gases. Incidental and intimately connected with oxidation of the metal is the absorption of gases. In melting the constituents of an alloy, a gas may enter into chemical union with some of its metals, forming oxides, or they may be occluded in the alloy. As an illustration: When silver is molten (1020 deg. C.), it can absorb about 20 times its own volume of oxygen. On cooling it gives up the oxygen absorbed, as evidenced by the well known spitting of silver on freezing. Absorption of gases is greater as the temperature increases. Since, when the

metals freeze, absorbed or dissolved gases are given up, if these are unable to pass through the metal before it freezes it will produce sponginess and blow-holes in the alloy. The same effect may be produced by air trapped in pouring, by gases evolved by molds or cores when hot metal enters them; but dissolved gas is unquestionably a principal source of porosity and blow-holes. All fuels used in the foundry at the present time contain sulphur in some degree. This sulphur is a very common cause of trouble. Melted brass absorbs sulphur greedily and gives it up on cooling in the sand molds and forms porosity and blow-holes. One successful brass foundry asserts that many of the failures usually attributed to oxygen are really due to sulphur. In the most careful crucible melting in coke-fired furnaces, the metal will absorb 0.002 to 0.005 per cent sulphur. Sulphur accumulates in a metal each time it is melted, which accounts for dark skin on re-run castings as compared with first melt metal. In fact, even though melted under a charcoal cover and CO blanket, copper needs a deoxidizer to free it completely from oxygen. These troubles should not occur in connection with electric melting, since the

TABLE VII. NON-FERROUS METALS MELTED IN ELECTRIC FURNACE

Metal	Condition of Metal Charged	State of Metal After Melting	Kw-Hr. per Ton to Melt	Metal Loss in Melting
Copper	Electrolytic cathode	Pig at pitch without rabbling or pouring	300	No oxidation; a certain amount of copper oxide is reduced
	Pig Scrap, heavy Scrap, light Scrap, dirty Chips, oily Chips, clean	Wire bar Foundry castings	to 500	
Zinc	Electrolytic cathode	Pig Foundry castings Billets for rolling Battery electrodes	90 to 120	Dross and oxidation under 2 per cent
	Pig Scrap, heavy Scrap, light Scrap, dirty Chips, oily Chips, clean	Wire bar Foundry castings Billets for rolling Battery electrodes	to 500	
Nickel	Shot Bar Scrap	Pig Foundry castings Billets for rolling	500 to 750	No oxidation loss
	Pig Scrap, heavy Scrap, light Scrap, dirty Chips, oily Chips, clean	Wire bar Foundry castings Billets for rolling	to 500	
Aluminum	Pig Scrap, heavy Scrap, light Scrap, dirty Chips, oily Chips, clean	Wire bar Foundry castings Billets for rolling	400 to 750	Less than 1 per cent oxidation
	Pig Scrap, heavy Scrap, light Scrap, dirty Chips, oily Chips, clean	Wire bar Foundry castings Billets for rolling	to 500	
Tin	Bar Pig Scrap	Bar Pig Wire	40 to 60	No oxidation
	Pig Scrap, heavy Scrap, light Scrap, dirty Chips, oily Chips, clean	Wire bar Foundry castings Billets for rolling	to 500	
Lead	Bar Pig Scrap	Bar Pig Wire	40 to 60	No oxidation
	Pig Scrap, heavy Scrap, light Scrap, dirty Chips, oily Chips, clean	Wire bar Foundry castings Billets for rolling	to 500	

furnace chamber may be kept uncontaminated and free from oxygen and injurious gases.

FIFTH SOURCE OF MELTING LOSS

Speed of Melting. The loss of zinc is proportional to the temperature and length of time the metal is held at the high temperature. This statement means that if you melt one charge at the rate of 100 lb. per hr., and a second charge at the rate of 200 lb. per hr., all other conditions being the same, the melting loss of the second charge will be less than that of the first charge. Electric methods of melting lend themselves to much quicker melting or higher melting rates than with fuel-fired furnaces.

DETERMINATION AND MEASUREMENT OF METAL LOSS

Metal loss in melting is ordinarily best judged from chemical analysis of the metals charged. This test eliminates errors arising from furnace walls, absorption or the reverse, and also the losses in pouring.

To show the inconsistency of the actual recovery method of loss test, results of comparative tests on coal-fired crucible furnaces and electric furnaces are given in Table IV. Crucible capacity 250 lb. Electric furnace capacity 1500 lb. The metal was poured from the crucible directly, whereas an auxiliary ladle was used to pour the 1500 lb. from the electric furnace, thus giving chances for greater loss in pouring.

Tables VII, VIII and IX show the average performance to be expected from the use of the electric furnace, with the furnace charge in different physical form, etc. Table X shows like results for fuel-fired furnaces.

FIG. 6. POWER REQUIRED FOR MAKING RED BRASS FROM DIRTY SCRAP IN ELECTRIC FURNACE

TABLE VIII. NON-FERROUS ALLOYS MADE IN ELECTRIC FURNACE

Metals	Condition of Metal Charge	State of Alloy After Melting	Kw - Hr. per Ton	Metal Loss, Per Cent
Red Brass				
Cu 80	Scrap pig, electro. cathodes	Foundry castings	250	0.25 to 0.75,
Zn 10	Scrap bar	Wire bar	225	to depending up-
Sa 6	Scrap pig	Billets	400	on manipulation
Pb 4				of furnace
Yellow Brass				
Cu 60	Scrap pig, electro. cathodes	Foundry castings	220	0.50 to 1.5
Zn 39.5	Scrap, pig	Wire bar		
Pb 00.5		Billets for rolling	350	

TABLE IX

Alloy	Condition of Alloy Charged	State of Alloy After Melting	Kw - Hr. per Ton	Loss per Cent	Temp. Deg. C
Red Brass	Yellow brass and copper or red brass and zinc, pig scrap and spruce, turnings and chips	Foundry castings	225	0.15	
		Wire bar	300	0.50	1300
Yellow Brass	Red brass and zinc or yellow brass and zinc, pig scrap and spruce, turnings and chips	Foundry castings	200	0.40	
		Wire bar, Billets	275	1.00	1100
Monel	Copper nickel Scrap and billets	Foundry castings, Billets	500		No oxidation
			750		1600
Aterite	Cu spruce, scrap Ni virgin metal Zn	Foundry castings, Billets for drawing and rolling	500	2% Zn, 32 per cent loss	1650

TABLE X. AVERAGE MELTING RESULTS, REALIZED IN THE AVERAGE FOUNDRY WITH FUEL-FIRED FURNACES

Type	Furnace Draught	Fuel, Kind	Per Ton	Metal Loss	Red Brass, Low Zn, 10 per Cent and Less	Yellow Brass, High Zn, More Than 10 per Cent
Pit	Nat.	Coke	1400 lb.	3.5	Red brass	
			1000 lb.	5	Yellow brass	
Pit	Forced	Coke	700 lb.	1.5	Red brass	
			600 lb.	2	Yellow brass	
Tilting	Forced	Coke	600 lb.	1.5	Red brass	
			400 lb.	2.8	Yellow brass	
Pit	Nat.	Coal	1200 lb.	3.5	Red brass	
			700 lb.	5	Yellow brass	
Reverb.	Nat.	Coal	900 lb.	6.2	Red brass	
			400 lb.	1	Yellow brass	
Pit	Bumers	Oil	50 gal.	1.5	Red brass	
	Tangential		40 gal.	3	Yellow brass	
Tilting	Open flame	Oil	60 gal.	2.2	Red brass	
	Atomizing					
Bumers			45 gal.	3.5	Yellow brass	
Tilting	Bumers	Nat. gas	4800 cu ft.	2.75	Yellow brass	
Tilting	Tangential					
Tilting	Bumers	City gas	7000 cu ft.	2.75	Yellow brass	
Crucible	Tangential					

The results given in the tables are average figures and will be influenced to meet any particular foundry by

- (a) Promptness of pouring.
- (b) Temperature.
- (c) Local conditions, such as physical condition of metal charged, its cleanliness, volume of air and products of combustion which pass through the furnace in natural draught furnaces.
- This varies from day to day, depending on the weather.
- (d) Design of furnace.
- (e) Manipulation of furnace.
- (f) Size of crucible.
- (g) Percentages of composition.
- (h) Length of working day.
- (i) Whether observations are based on hot furnace and hot crucibles or whether the first heat of the day is excluded.
- (j) Whether pouring light or heavy castings. Pouring light castings requires hot metal, and pouring heavy ones requires metal at lower temperature.
- (k) Whether results are from careful tests or whether they represent actual foundry or rolling mill practice and extend over a considerable period.

Curve sheet (Fig. 6) illustrates how the furnace which is able to turn out metals for 300 kw-hr. per ton requires in reality an average of 350 kw-hr. per ton due to foundry handicap.

CONCLUSION

In conclusion, the chart, Fig. 7, shows the excess cost for melting brass, and is made up from curves and tables preceding it. It is assumed that all the brass in the country is melted, (1) in fuel-fired furnaces, all types being employed equally; (2) that the same work

FIG. 7. CHART SHOWING EXCESS COST MELTING BRASS

is done in the electric furnace. The cases of red brass and yellow brass have been considered. Four conditions are shown, viz.: 10-hr. day—(1) melting yellow brass, (2) melting red brass; 24-hr. day—(3) melting yellow brass, (4) melting red brass.

The shaded portion of each wedge shows the saving in total cost between melting with fuel and with electricity. This chart stated in words and figures is as follows:

Furnace	Alloy Melting	Length Working Day, Hr.	Per Cent Saving Over Fuel Fired
Electric	Yellow brass	10	100
Electric	Red brass	10	80
Electric	Yellow brass	24	110
Electric	Red brass	24	70

These margins of savings are of such magnitude that we cannot longer doubt that the electric furnace is destined to dominate completely the brass-melting field.

Potassium Permanganate From Ferromanganese by Electrolysis

BY M. DEKAY THOMPSON

THE fact that permanganate is produced by the electrolysis of manganese or ferromanganese anodes in alkaline solutions was first recorded by R. Lorenz (*Z. f. anorg. Chem.*, vol. 12, p. 393, 1896) in a brief notice which gave no further information than the statement above. The anodic behavior of manganese in solutions of sodium sulphate alone and with additions of sodium hydrate, and in solutions of acid sodium phosphate (NaH_2PO_4), with and without additions of sodium hydrate, is the subject of part of an article by W. J. Müller (*Z. f. Elektrochem.*, vol. 11, p. 755, 1905). His principal result is that hydroxyl ions produced passivity, as shown by potential measurements.

A study of ferromanganese anodes in caustic soda solutions was made by G. R. White (*J. Phys. Chem.*, vol. 10, pp. 502-513, 1906). This paper, however, is largely taken up with a discussion of the reduction of permanganate to manganate in alkaline solutions, and scarcely any electrochemical data are given. The anode current densities were 2.5 to 12.5 amp. per sq.dm., the temperatures from 20 deg. C. to 95 deg. C., the concentrations 2 to 10 per cent. The maximum current efficiency was 12 per cent (under what conditions is not stated).

C. J. A. Griner patented the process of making permanganate by the electrolysis of manganese carbide anodes in concentrated sodium hydrate (German patent 125,060, July, 1900). It is claimed that manganese carbide anodes are superior to ferromanganese, as it is stated ferromanganese anodes have to be cleaned frequently on account of the formation of manganese dioxide, and also the yield with these is low. This patent evidently has no value, as manganese carbide decomposes water with the formation of hydrogen and methane. (Roscoe and Schorlemer, vol. 2, p. 1155.)

EXPERIMENTAL WORK ON THE ELECTROLYTIC METHOD OF MAKING POTASSIUM PERMANGANATE

The object of the following work (carried on in the spring and summer of 1918) was to see whether this method of making potassium permanganate could be used commercially. The ferromanganese used had the following composition:

	Per Cent.		Per Cent.
Manganese.....	75.1	Silicon.....	0.9
Iron.....	16.7	Phosphorus.....	0.2
Carbon.....	6.1		
		Total.....	99.0

It also contained copper, nickel, calcium, magnesium, and arsenic.

Small-scale experiments with a solution of potassium hydrate containing 24 g. per 100 cc., with an anode current density of 20 amp. per sq.dm. (180 amp. per sq.ft.) at 45 to 50 deg. C. showed that the electrolysis proceeded for a few hours with a current efficiency of 15 per cent, but that there was a coating of oxides formed on the anode, which gradually protected the metal beneath from the further action of the current. An attempt to overcome this by using a pulsating current was not successful.

On replacing the hydrate solution by a 20 per cent carbonate solution no further trouble was encountered by the scale protecting the metal, other conditions remaining the same.

On a subsequent occasion, when the hydrate solution was used again, the anode was not attacked, but gas was evolved instead. This would appear to be a case of passivity, which was doubtless due in part to the hydroxyl ions. Why it appeared in this case and not in the first experiments is not clear.

EXPERIMENTS IN LARGE CELL

The next step in the evolution of this process was to try it on a semi-commercial scale. A cast iron plater's tank of the following inside dimensions was used: at top, 53 x 33 cm., at bottom 47 x 26 cm., and 38 cm. deep. A wooden pattern 2 cm. thick, of the shape of an anode used in copper refining, was made, and several attempts were made at casting anodes in a closed sand mold. The metal was melted in a Dixon graphite crucible in a pot furnace, requiring about four or five hours. It poured and filled the mold, but the metal always cracked on cooling. It was found subsequently that this could be prevented by cutting vertical slots in the pattern, but the anodes used in this tank were made by casting bars of the metal in open sand molds, and attaching these to an iron crosspiece. They were not annealed. A hole was left in one end for a bolt. The dimensions were 2.5 x 5 x 36 cm. The cathodes were sheet iron, the diaphragms asbestos cloth bags, the edges held together by bent iron strips. On account of the expense, the quality of the asbestos was not as good as that used in the small-scale experiments, and holes could be seen in it on holding it up to the light. An attempt was made later to improve the diaphragms by painting them with some of the anode mud. There were five anodes and six cathodes. The experiments were not successful, because the cell heated up to 70 deg. C. from the passage of the current and this caused a layer of oxides to form on the anode, which prevented electrolytic attack, as in the case with hydrate solutions. The electrolytic tank was then placed in a tub through which tap water circulated. This kept the temperature down to 40 deg. C. and there was no further difficulty and the anodes never needed cleaning. The current used was limited by the temperature of the tap water, which allowed only a limited amount of cooling. In the following runs the full number of anodes was not always used because of breakage. The current density was approximately 7 amp. per sq.dm. (65 amp. per sq.ft.) at about 4.2 volts, and the total current about 350 amp. The concentration of potassium carbonate was maintained at about 200 g. per liter. The volume of electrolyte was about 35 liters. The electrolysis lasted only from 9 a.m. to 9 p.m. and the cell stood idle over night. After electrolyzing four or five days, the liquid and anode mud were removed and heated to about 90 deg. C. to cause all permanganate crystals to dissolve. The liquid was then filtered through a large asbestos filter under suction, and the filtrate was allowed to crystallize. The anode mud was removed from the filter, was washed several times with hot water and the wash water added to the main solution, but it would have required many washings to get the mud free from permanganate and carbonate. Even after four washings crystals of permanganate would appear on the surface of the mud on drying. This suggested the idea that it would be more efficient to allow the mud to dry before the final washings, and while no accurate data were obtained to confirm this point, this procedure did seem to give better results.

On cooling, the mother liquor was drained off and the

crystals centrifuged with a little washing by sprinkling. They analyzed over 98 per cent pure. Approximately 40 lb. was made during these experiments.

RESULTS WITH LARGE CELL.

No	Amp	Amp Hr.	Kg K ₂ MnO ₄ Produced	Per Cent Current Eff.	Kw.-Hr Per Kg.	Per Cent Mn Converted to Anodes, K ₂ MnO ₄	Loss in Weight of Anodes, Kg.
2	350	17,370	1.68	11.0	44		
3	350	16,000	2.00	17.6	32		
4	350	21,200	3.84	21.6	25		
5	350	18,880	2.79	18.6	30	34.5	3.78
6	350	19,820	2.15	13.2	40	62.5	2.1
7	350	21,330	3.42	19.2	28	62.5	2.52
Average.....				17.0	33		

The total anode mud made weighed 21.5 kg., the permanganate 20.7 kg. A considerable portion of this mud was found in the cathode compartments, showing that permanganate diffused through the diaphragm and was reduced. This would occur to a less extent with better diaphragms, and would increase the current efficiency.

It was found that the anodes were attacked very much more near the surface of the electrolyte than at the lower end, evidently on account of relatively poor electrical conductivity of this alloy. It would therefore seem advisable to cast the anodes with a taper toward the lower end.

These experiments sufficed to determine only the cost of materials and power for the manufacture of potassium permanganate. These are the following, assuming the ferromanganese to cost \$260 per 2240 lb., power \$20 per hp.-yr., and 85 per cent potassium carbonate 40c. a lb.:

Required for 1 lb. of potassium permanganate:

1 lb. ferromanganese.....	\$0.12
15 kw.-hr.....	.05
0.52 lb. 85 per cent K ₂ CO ₃	.21
Total.....	\$0.38
For 1 kg. the cost would be.....	\$0.84

Other expenses of this manufacture which would have to be determined by a small experimental plant are: Cost of casting anodes, cost of installation, labor, etc. The anode mud, consisting of oxides of iron and manganese, could doubtless be sold for something.

Since writing the above an article on sodium permanganate by Wilson and Horsch¹ has appeared.

The results of their work differed from those above in that the higher current efficiency of 35 per cent was obtained, and 7 volts per cell were used. Perhaps the most important difference is that the anodes had to be cleaned by sand-blasting every 24 hr. In order to see whether this was due to using sodium carbonate in place of potassium carbonate, the original anode used by me was tested in sodium carbonate, without cleaning since last used in potassium carbonate.

The results were the following:

G. Na ₂ CO ₃ per 100 cc.....	15.7	Amp per sq. dm.....	5.2
Duration, hr.....	85	Amp hr.....	254
Temp. deg.....	40	Per cent current eff.....	20.5
Volts.....	4.2	Per cent Mn converted to MnO ₂	66

The run was continuous for 3, 26, 27 and 30 hr., but the anode was not cleaned at any time. This shows the lack of necessity for cleaning the anode is a property of the anode, as it behaves the same in sodium carbonate as in potassium carbonate, at this temperature.

Some ferromanganese used by Wilson and Horsch,

which required periodic cleaning when used as anode was analyzed, with the following result:

Manganese.....	78.5	Silicon.....	1.2
Iron.....	13.8	Phosphorus.....	0.2
Carbon.....	6.8	Total.....	100.5

The principal difference between this alloy and that used in the above work is that this contained about 3.5 per cent more manganese and a corresponding less amount of iron. This would hardly seem to be sufficient to account for the different anodic behavior, but in order to test this point an anode was made by melting some of the 78.5 per cent ferromanganese with the calculated amount of steel turnings to make 75 per cent ferromanganese. This anode was not analyzed, so the composition may not have been exactly that desired. This anode electrolyzed for a longer time without requiring cleaning, but eventually the voltage did rise and the scale had to be removed before the electrolysis could be continued. This merely indicates that the anodic behavior of ferromanganese is quite sensitive to its composition.

The author hopes to resume this investigation later, but as the work has to be discontinued for the present, it is not considered advisable to delay further the publication of the results obtained.

SUMMARY

These experiments show it is possible to manufacture potassium permanganate from commercial ferromanganese, containing about 75 per cent manganese, by electrolysis in a potassium carbonate solution without the necessity of ever cleaning the anodes. The temperature must not be allowed to rise much above 40 deg. C., for if it does an insulating coating of oxides is formed, which prevents the production of permanganate. Carbonic acid is not lost in the electrolysis. The current efficiency was about 17 per cent, but it would be higher with better diaphragms. The current density was 65 amp. per sq.ft. The anodes are attacked more at the top than at the bottom.

The anodic behavior, as regards formation of insulating scale, is affected by a small change in the relative amounts of iron and manganese in the anode.

Massachusetts Institute of Technology,
Cambridge, Mass.

Short Course in Ceramic Engineering

The Department of Ceramic Engineering of the University of Illinois is engaged in making preparations to give a two-weeks short course in ceramic engineering in February, 1920. This short course will follow in general the same lines as the short course given in 1918, and will include lectures and laboratory work in the physics and chemistry of ceramic materials and processes; mining, sampling, handling and testing of clays; shaping, drying and burning; machinery and equipment for the ceramic plant; refractories, glass, glazes, etc. The complete program of the course will be sent free to all who apply for it. The course is open to any person interested.

Explosive Plant at Nitro Sold

After some negotiation with bidders the Government has sold its explosive plant at Nitro, W. Va., to the Charleston Industrial Corporation of Charleston, W. Va. The figure agreed upon was \$8,551,000.

¹Trans., Am. Electroch. Soc., April, 1919.

Industrial Magazines and Labor Conditions*

BY HARRY E. CLELAND

IN JULY and August of this year there was an average of 336 strikes going on daily in the United States.

In the general fog there are at least two things clear: First, that there has been a pronounced and progressive decline in production. Second, that shorter hours and higher wages have not been compensated for by increased efficiency.

That portion of capital and management which regards labor as a commodity to be bought and sold, hired and fired must come out of its comatose condition. And that portion of labor which looks upon capital as an arch enemy and which is ruled by its radicals must throw the hobgoblin to the scrap heap and consign the swashbucklers to the same place.

Capital cannot afford to be reactionary. Labor cannot afford to be revolutionary.

There must be a real partnership before there can be a true industrial democracy. Fundamentally, real partnerships are based upon mutual confidence. Labor unrest is the result of a lack of such confidence.

Labor thinks that its cravings will be satisfied with more money. That is not true. Capital thinks that all that labor wants is more money and certainly labor does everything to give capital that idea. That, too, is untrue.

Labor wants a decent living wage based on what it produces plus as much interest in the things it produces as is possessed by the other hired men in the front office.

Business papers are the organs of industrial management in this country.

LABOR QUESTION WITHIN SCOPE OF BUSINESS PAPERS

It has been recognized for years past by the ablest business papers that the labor question as such comes within their sphere of activities. You will find that business papers as a rule have had and will have some constructive things to say on capital, management and labor, with the added advantage that they are not of necessity confined to the glittering generalities of the question but are able, because of their highly specialized character, to focus their comments upon the particular labor problems of the single industry they represent.

In the new light of things they will recognize fundamentally that capital and management are very seldom one and the same thing. Management is usually a hired man exactly as is any other worker in the plant.

And business papers will write it down as a basic principle that management must manage not only for the interests of capital but for the interests of labor as well. Otherwise its job is poorly done for both parties to the transaction.

Business papers, I believe, must point out clearly to their readers that a new industrialism is at hand. They must show that capital, management and labor are infested with certain fallacies and that these must be removed before any basis of mutual understanding can be reached.

It is a fallacy on the part of labor to say that production must be curtailed and that labor-saving machinery must be fought in order to make more work for more people.

It is a fallacy for labor to believe that it is the sole creator of wealth. The products of industry are only partly the work of labor.

It is a fallacy for labor to believe that the objects sought by capital are opposed to the objects sought by labor.

It is a fallacy for management to assume that it is accountable only to capital.

It is a fallacy for management to regard labor as a commodity to be bought and sold according to the law of supply and demand.

It is a fallacy for capital to contend that it is the sole factor because it supplies the funds.

It is a fallacy for capital to assume that it has no responsibility beyond supplying the funds.

It is a fallacy for capital to contend that all profits belong to it.

PAPERS SHOULD EXPOSE ALL PROFITEERING

I believe that business papers must expose to the light of publicity every flagrant case of profiteering it finds whether it be on the part of capital or labor. The man who pays \$18 a ton for pig iron and sells it for \$55 is a profiteer. The worker, who, having received advances amounting to nearly 75 per cent in two years, now demands—as New York printers are demanding—an immediate further increase of 65 per cent, is a profiteer plus. Certain elements of labor are howling to high heaven about the pitiless profiteers, but when it comes to sheer and unadulterated arrogance in profiteering, I commend you to the average insurgent union which, having broken loose from the wiser counsel of its international leaders, runs its rampant ruining race.

Business papers must report the progress, success or failure of all attempts on the part of capital, management and labor to form industrial democracies within the individual plants. They must show plainly why such attempts succeed or fail. Already there is a wealth of material. The pioneering of such concerns as the Colorado Fuel & Iron Co., the Midvale Steel & Ordnance Co., the International Harvester Co., Hydraulic Pressed Steel Co., the Multigraph Co. and many others is a matter of vital importance to every man, woman and child in the country.

Business papers should advocate that capital choose its managers on a basis first, of their ability to handle men, second, of their technical skill. The reverse has been the rule. And the reasons for this are so apparent that why any other course should have been chosen will remain a mystery always.

Why is it that one concern pays its men an average of \$38 a week and gets unswerving loyalty and full production while another in the same locality pays an average of \$41 a week, has labor trouble continuously and never reaches full production? It is because the manager of the first concern treats the workers like human beings, makes a point of knowing them personally, takes them into his confidence, and makes their shop life something more than a daily grind, while the other tries to cultivate loyalty with a slide rule and a micrometer.

Loyalty—and loyalty means production—is only incidentally a matter of money and hours; loyalty is

*Abstracts from a paper read before the Associated Advertising Clubs of the World, New Orleans, September, 1919.

a matter of mind and heart, and you can't produce it by any strong-arm methods—to get, the concern must give.

THE OPEN SHOP ADVOCATED

It is also my belief that business papers should advocate the open shop.

The closed shop is un-American, and nothing un-American should be tolerated for a minute. Every American is born with or inherits the right to say where he shall work. Every American employer has the right to say whom he shall hire.

The closed shop tends to put all workers on the same dead level of mediocrity, throttles individuality, stifles initiative, curtails production and destroys the dignity and power of labor.

The opportunity for individual initiative, the possibility for any workman to become a master, has made this country what it is in manufacturing and all other industries.

The closed shop means the changing of all this to the foreign standard, where a workman is always a workman, where ambition is still-born and hope is dead.

The open shop means the freedom of every man to do what he thinks best for himself, provided he does not encroach upon the liberty of others.

This imported closed shop, that prevents young men from learning the trade; that restricts output; that keeps improved machinery products down; that forbids the owner of the plant from having his own foreman or any other representative in the workroom, is in itself wrong. It is against the liberty of men. It is slavery. It cannot be tolerated in a free country.

CAUSES OF LABOR TROUBLE

I said awhile ago that business papers ought to look into the causes of labor trouble and seek a remedy.

One of the principal causes of labor trouble is the reduction in piece rates.

If the worker on piece rates does exceptionally well and makes big money he is afraid, and usually justifiably, that his rate will be cut. In those circumstances, he produces just enough to make what seems to him will correspond to his possible maximum wage.

For instance: A boy in a New England factory was tapping nuts at a piece rate of 10 cents a hundred. His average production was 3000 nuts per day. One day he overheard the superintendent tell his foreman that the concern had decided to quit making that particular kind and size of nut. In that one day the kid tapped 8200 nuts!

No matter whether the employer pays by bonus, differential piece system, premium or what not, he must play fair if he expects full production. Business papers must advocate the square deal.

Now let us find out as nearly as we can what the sentiment of business in this country is on the labor question.

SENTIMENT OF THE COUNTRY AS POLLED

The United States Chamber of Commerce submitted 13 principles of industrial relations to the vote of its member organizations representing business associations of all kinds. Capital and management did this voting, mind you, not labor.

Four hundred and thirty-three organizations filed

ballots in 44 States, the District of Columbia, Alaska and Hawaii. The vote was overwhelmingly in favor of 12 of the principles, and the Chamber of Commerce is now committed to the following:

1. Industrial enterprise, as a source of livelihood for both employer and employee, should be so conducted that due consideration is given to the situation of all persons dependent upon it.

2. The public interest requires adjustment of industrial relations by peaceful methods.

3. Regularity and continuity of employment should be sought to the fullest extent possible and constitute a responsibility resting alike upon employers, wage earners and the public.

4. The right of workers to organize is as clearly recognized as that of any other element or part of the community.

5. Industrial harmony and prosperity will be most effectually promoted by adequate representation of the parties in interest. Existing forms of representation should be carefully studied and availed of in so far as they may be found to have merit and are adaptable to the peculiar conditions in the various industries.

6. Whenever agreements are made with respect to industrial relations they should be faithfully observed.

7. Such agreements should contain provision for prompt and final interpretation in the event of controversy regarding meaning or application.

8. Wages should be adjusted with due regard to the purchasing power of the wage and to the right of every man to an opportunity to earn a living at fair wages, to reasonable hours of work and working conditions, to a decent home, and to the enjoyment of proper social conditions.

9. Fixing of a basic day as a device for increasing compensation is a subterfuge that should be condemned.

10. Efficient production in conjunction with adequate wages is essential to successful industry. Arbitrary restriction on output below reasonable standards is harmful to the interests of wage earners, employers and the public, and should not be permitted. Industry, efficiency and initiative, wherever found, should be encouraged and adequately rewarded, while indolence and indifference should be condemned.

11. Consideration of reduction in wages should not be reached until possibility of reduction of costs in all other directions has been exhausted.

12. Administration of employment and management of labor should be recognized as a distinct and important function of management and accorded its proper responsibility in administrative organization.

13. A majority was in favor of the thirteenth, which had to do with national employment offices, but it did not receive the required two-thirds vote.

Doesn't the action of the Chamber of Commerce look as if the spirit of fair play were abroad in the land?

There will always be differences of opinion, but they need not lead to riot and rape, bloodshed and murder, closed factories and open almshouses.

Fair play and co-operation fully exercised between capital and labor is after all a sovereign remedy for the ills of both. Co-operation saved the world. It can save this situation.

America's Case in Chemistry*

BY ELLWOOD HENDRICK

TOWARD the end of the eighteenth century, and in the beginning of the nineteenth, there were in this country distinguished and active contributors to research in chemistry. We have but to read the charming biographies of that delightful savant Dr. Edgar S. Smith, provost of the University of Pennsylvania, to appreciate not only the scholarship attained by such men as James Woodhouse, Robert Hare, Benjamin Silliman and others, but also their very considerable gifts to the common store of knowledge and understanding. It will be recalled that in those days Joseph Priestley, having discovered oxygen in England, came to America, not only to enjoy freedom of worship, but, being Unitarian in religious disposition, in order to avoid in a literal sense the brickbats of orthodoxy. To the end of his days Priestley held to the theory of phlogiston. It was an idea fixed in his mind that every dancing flame was a manifestation of the escape of this imaginary body, except when the ash weighed more than the burned substance. Then phlogiston was assumed to reverse itself and go backward. Woodhouse was modern in his views of combustion, championing those we hold today, following Lavoisier in France, and Klaproth in Germany. He had a doughty opponent, and, since Priestley spoke with great authority, the battle waged long and fierce, till the Englishman cried quits, although he remained unconvinced to the end of his days. I know of no more illuminating sidelight to throw upon the quality of the men at that time engaged in science in the United States than to point out that whenever Priestley was attacked on any other ground than that of the scientific heresy of phlogiston, Woodhouse would rush to his aid, supporting him in all his dignity as a great philosopher in science. Then, for a long time, chemistry seemed almost forgotten.

FRANKLIN'S AID TO SCIENCE

As a reason for this I venture to propose that in our earliest days as a nation we had a world figure in Benjamin Franklin, who was intensely interested in science, to aid us. It was he who advertised research in physical science in America. Now business men know the value of advertising. If they sell goods in packages with a trade mark, and can get this trade name sufficiently talked about, they can dispose of their product in vast quantities, and at a higher figure than the market price for the same goods. Other merchants may hold vast stocks of the identical wares and be unable to find a market for them. In later years scientific achievement in this country was sporadic, the contributions came from men born to their work, while recognition was infrequent and difficult to obtain. Joseph Henry would have been the master of physics that he was under any circumstances, but even today we do not accord him the full honor to which he is entitled. Simon Newcomb would have been a great astronomer whether he went to Washington or not, and Willard Gibbs worked in utter loneliness because his own colleagues did not appreciate or even understand him. Unlike the model child who may be seen but not heard, the man of science may be neither seen nor heard while engaged at his

task. And afterward his findings are likely to be recorded in language almost cryptic, so that whatever rewards attach themselves to his name seldom reach him during his lifetime. Or if they do, they lack the trumpet-and-drum quality that appeal to us in youth while we are determining what career we shall pursue.

Had Abraham Lincoln or Theodore Roosevelt been a chemist the profession of chemistry would have had a far higher standing in this country than it has enjoyed. It would not have got out of focus. Even in public pronouncements these men, whose every word had news value, would have employed the illuminating chemical similes which are now slowly finding their way into the public consciousness.

The profession, I repeat, was out of focus. We did not have chemists enough because the subject was not talked about enough. Now, the special bent of brilliant minds is not always disclosed in youth. They have to feel their way along until they strike their *metier*, and it goes without saying that many a brilliant mind would have addressed itself to chemistry had the subject enjoyed the general consideration which is warranted by its importance. Chemistry was, in fact, a learned profession long before the tradition lost weight that law and divinity were the only suitable callings for a thoughtful man.

WAR REVEALED IMPORTANCE OF CHEMISTRY

When the great war came upon us the eyes of the people were opened. Chemists were suddenly needed, needed as never before—and how ours responded the world knows. We should not let the occasion pass without mentioning the ringing appeal of Dr. Julius Stieglitz of Chicago, then president of the American Chemical Society. Dr. Stieglitz knew neither rest nor sleep until he had sounded the country's resources in chemists and, with Dr. Parsons and the Bureau of Mines, had completed the rapid census of available men. We must note the competent organizing ability of Dr. W. H. Nichols that was called into play, and the forward march to Washington of chemical manufacturers who placed all their possessions at the service of the Government. Nor must we forget the organization of the Naval Advisory Board, and the earnest, constant and weighty contributions of such men as Willis R. Whitney and Leo H. Baekeland, the American University and its passionate tension of work in research, the seven-league boots in which W. H. Walker strode to production at the Edgewood Arsenal, the great work of by far too many of our leaders in chemistry even to name them in passing, and the thousands of glorious young men who rushed in from universities and laboratories, the country over, and threw themselves into the mighty effort. It was great, it was magnificent, and it showed the spirit of America as surely as this was shown by our soldiers on the battlefield. Neither did the Chemical Warfare Service fail. Working together with the British and the French under General Fries, it was ever on hand, the laboratories co-ordinating with the front, stubborn in defense, valiant in attack, until victory was won. It is a glorious record.

But here again we need the Voice of Authority in council. We lack our Benjamin Franklin to whom public opinion and men in office will give heed. We have no one who speaks with the Voice of Authority in science to the types of mind represented, for in-

*Paper read at the Fifth National Exposition of Chemical Industries, Chicago, Sept. 23, 1919.

stance, in the Congress of the United States. We have the men, and these men can speak, but Congress will not listen. Neither will others who also should give heed.

The fact is brought home to us by the passing of the Chemical Warfare Service. This organization provides a means of overcoming an unprepared enemy without loss of life even, since, by proper use of lachrymator or other gases, enemy soldiers may be put *hors de combat* and taken prisoner *en bloc*, and yet they recover in a few hours, fully restored to health. We have learned that, given on the one side chemical preparedness, and unpreparedness on the other, the army thus scientifically equipped is almost certain to win, while the unprepared opponent is equally likely to lose. After the Germans launched their first chlorine attack against an unprepared enemy the Channel ports were wide open to them, and why they did not take them is still unexplained. This first attack with gas was an ethical breach, the responsibility for which will always rest with the Germans, but when the convention had been broken and gas came into use, it straightway became a recognized instrument of warfare, employed by all.

USE OF GUNPOWDER ONCE CONSIDERED UNSPORTSMANLIKE

It was started, just as once upon a time the use of gunpowder was started. The early introduction of shooting an enemy beyond the range of the bow and arrow was condemned as unsportsmanlike, and it *was* unsportsmanlike. It is far more valiant and manly in every way to meet an enemy face to face, sword in hand, in battle array, and fight it out with him in the open, than to murder him unawares. But the advantage rested with gunpowder, and accordingly gunpowder remains in use. We have also learned that if both sides are prepared and equipped, then chemical warfare is the most humane method of fighting yet devised, and that, while it kills, it leaves hardly any soldiers maimed or seriously incapacitated. As for the argument that chemical attack may be carried so far as to blot out entire nations, this may be an argument against war in any form, and in favor of a League of Nations, but it will not prove a deterrent to the nation that is using it. Wars usually occur as the result of some breach of convention or of promise. And even if we establish the convention that chemical warfare shall be forbidden, none the less we should keep ourselves at all times fully informed concerning it. Otherwise we are placing our country and our people at the mercy of any power that may see fit to break its word. So we chemists hold that the work done in providing this instrument for our army, and in organizing laboratories for service, offensive and defensive, in chemical warfare, should be maintained as a regular branch of our military system, whether we ourselves adopt the convention forbidding its use or not.

This has been said, and urged, and repeated, and printed, again and again, but the West Point traditions are stronger than our utterance, if not than our argument. The Chemical Warfare Service for the most part has been scrapped. It is about to be filed, rather than turned over to the Corps of Engineers—for there is hardly enough left to turn over—provided the present army reorganization bill now before the

House is adopted. And even to-day to equip the Corps of Engineers with a competent chemical service would require, not only that much of the work be done over again, but that the Army should have something which the General Staff seems resolved not to have, and that is chemists!

CHEMISTS MUST EARN RECOGNITION

The Voice of Authority is not achieved by cultivation. It does not depend on pitch, nor on tone. It must be earned rather than trained. But sometimes its failure to function is due to the deafness of the auditors, and it may be that the Great American Ear is not yet sufficiently attuned to the call of Chemistry to hear even so urgent an appeal as that our Chemical Warfare Service be retained. In the bill for the reorganization of the Army now before Congress, the plans for the distant future are rosy enough. A great institute for scientific research is provided as an additional part of the Corps of Engineers, but for the present we chemists hold that if research is to continue, it must remain a separate corps. We recall the amazing wastes in preparing for war due to the lack of understanding of chemical reactions by men in authority, and we fear that if chemistry is now made a subordinate department of the Engineers, it will cease to function. The chief of the division, whose time in days of peace is devoted to the improvement of rivers and harbors and the digging of canals, is likely to detail the least useful engineer officers to direct chemical research. And that will mean, so far as chemical warfare is concerned, defenseless America once more!

THE BRIGHTER SIDE

So let's take a hitch in our belts and look to the morning. We are doing pretty well in industry and teaching. In pure research we are holding our own, and the outlook is good. There have lately appeared the Langmuir Postulates in regard to the constitution of atoms and molecules that are epoch-making. The lucid explanations of the nature of the nitrogen molecule as compared with its atom, of the characters of the halogens and the alkali metals, of carbon monoxide, and of other problems, are vastly illuminating and helpful. The researches of Professor W. D. Harkins of Chicago, always interesting and worth while, the great authority among chemists the world over achieved by the work of Theodore W. Richards of Cambridge, Mass., the clear thinking of G. N. Lewis of California, the masterly accomplishments of Edward C. Franklin on the ammonia system of acids, bases and salts, the constant and repeated flashes of light thrown from the brilliant mind of Wilder D. Bancroft—only to mention a few of our masters whose work suggests itself in passing—all are indicative of the fact that the chemists of America are alive—alive and awake. It is theory and not a condition that confronts us in chemistry, and unless we are sound in our theories of chemistry we are bound to fail.

In regard to teaching, we have the men and we have the students. We also have an advantage that is peculiarly noticeable in this country: we work together in both pure and applied science. In other words, chemistry is ready for industry. On the other hand, we are somewhat careless in the training of the imagination and the requirements of general culture de-

manded of our students. This is no appeal for chemical snobbery; it is rather an appeal for recognition of the fact that the man of research needs a trained imagination. And in industry especially it is needed that the chemist be proficient in that greatest of the arts, which is the art of living. In industry he meets men whose lines have not fallen in pleasant places. Here are those who have not had a fair chance, and he can give it to them. The chemist represents the scholastics and philosophy of manufacture. He can contribute the guiding hand, the thoughtful advice, the pleasant leadings that never can be put into the pay envelope. It is in the factory that his culture, his scholarship and his grace of living are most needed. Nor are we as generous as we might be in rewarding our professors with money, or with that which is equally important, the honors that are warranted by their posts of influence.

Industry has taken notice of chemistry, but it has not yet completely wedded itself to science by availing itself of its opportunities. There is need of many more general commercial laboratories than can find support. We need more industrial research. Again, we have not yet learned the need of men with trained scientific minds on boards of directors of corporations engaged in chemical manufacture. This is a serious defect, and its results are frequently shown in the inertia of industry in failing to profit by improvements that would make for great economies as well as for advancement in well-being. Most of us are familiar with large industrial establishments, the processes of which are based on chemical reactions, and these corporations are operated from the standpoint of salesmanship, banking and law. The company's legal advisor sits in council to pass upon contracts and procedure in dealings with men, but the chemical advisor who understands materials, and who, therefore, is responsible for the company's products and its good repute, is generally left out in the cold. American industry at large, with only a moderate number of exceptions, is still deficient in its calls upon the man of science to its councils.

NO SOLE RELIANCE ON A TARIFF WALL

Whenever such calls are made the American chemist has responded and has set himself to work with diligence. That so many of his efforts have been crowned with success is pleasant to contemplate—but the way of progress does not lie in contemplation alone. We are in the race with the wide, wide world. In some respects we are ahead, and in others we are behind. We cannot lean back and fold our arms in the belief that a high protective tariff will assure us success. We must maintain the co-ordination between pure science and that which is applied. We must hold up the hands of our great teachers and encourage them in their arduous task. We must increase the honors and distinction of their offices, and make the post of teacher as desirable as possible. We must do what we can to discover the exceptional man, and to create opportunity for him, because often the exceptionally gifted in research lack the gift of finding places for themselves. We must preach the gospel of chemistry, and bear its evangel to spots where its light is still unknown. And we must, in one way or another, conjure up the Voice of Authority so that it may speak for us!

Let us borrow an example from Arthur D. Little to show how the Voice of Authority might aid us. The water flowing incessantly over Niagara Falls represents the same power, the same energy, as would be obtained by the burning of a prodigious amount of coal. Except for the cost of installation and the slight charges for maintenance, it would be possible to use the power of that falling water in exchange for a colossal coal bonfire, developing the same energy expressed in terms of heat, for the edification of visiting brides and bridegrooms. Let us imagine this done, with miners working, and trains rushing constantly day and night, to feed this unheard-of bonfire. Suppose the Voice of Authority could present this picture to the public so that all could visualize the thousands of men at work, and the immense capital represented in the cost of the coal and its transportation—and all of it going up in smoke! Suppose it were made clear that none of that coal is being used to propel ships to and from Europe and trans-ocean markets, nor to give us warmth, nor to drive the wheels of industry, but that it is being spent, simply to keep our huge, international bonfire forever burning, and that people are paying for this spectacle in the increased cost of living, while the tremendous fund of power goes to waste. With this fact made clear—that that falling water represents an equivalent in millions of tons of coal which are charged to the people of this generation, these same people would soon declare themselves in favor of taking profit from that inexhaustible power for the benefit of the two countries it lies between, for the benefit of ourselves and Canada!

CHEMISTS MUST SHOW INTEREST IN PUBLIC AFFAIRS

We need the Voice of Authority to put a stop to waste of power, waste of fuel, waste of wood, waste of materials and waste of labor—and waste of men! We need this Voice to point out to us the way of progress.

I believe that we can conjure it up, not as the utterance of one individual, nor in the shout of thousands of voices, crying in unison. It will come, but rather in the benediction of things done. I believe we can accomplish it if, as chemists, we interest ourselves intensely in public affairs, struggling with all our might, both individual and collective, for the public weal, by doing this daily, and without thought of personal reward. If we dig into public affairs with diligence, preaching the gospel of chemistry with all the ardor of insistence shown by the Ancient Mariner in telling his weird tale, then, in time, our message is bound to be heard and heeded. Indeed, then, with God's help, we may advance toward a greater enlightenment, with a better art of living, and in a better-ordered world, where justice and peace abide.

American Electrochemical Society Meetings

At the last meeting of the board of directors of the American Electrochemical Society it was decided to hold the next meeting in Boston, April 8, 9 and 10, 1920. The American Institute of Electrical Engineers meets about the same time and a joint session will be held on April 10 on the subject of electrically produced alloys. Another feature of the meeting will be a symposium on colloids under the direction of the president, Wilder D. Bancroft.

Heat Treatment of 155-mm. High Explosive Shell *

BY WILLIAM J. MERTEN

HEAT treating the 155-mm. shell had been the cause of worry and delay in production in almost every plant manufacturing this size and type of projectile. Consequently, when the Twin City Forge & Foundry Co. entered upon large-scale production, I was informed from all sides that the man responsible for the heat-treating practice had a real metallurgical job, and consequently I was naturally guarding against any of the things which my experience had taught me to avoid, so that we could get results right from the start.

a position that the darker or cooler part of the metal might be exposed or subjected to direct impingement of flame. To this seemingly small and unimportant change I attribute more influence toward our success in heat treating than to any other single item in the chain of improvements over the style of equipment ordinarily used heretofore. Especially was this of extraordinary advantage in the drawing furnace, since an even temperature as low as, say, 1250 deg. F. is rather difficult to attain unless the shell may be juggled without having the rest of the load follow along by gravity and eject the one from the furnace before it has become "evenly heated." This one item of "even heat" is unquestionably the most essential factor and requirement to give satisfactory results.

FIG. 1. PLAN OF HEAT-TREATING DEPARTMENT AND AUXILIARY SERVICES

After a very thorough deliberation with our engineering department the following described equipment and layout was decided upon:

EQUIPMENT AND LAYOUT

Three batteries of oil-fired Ferguson furnaces with inclined floor and perforated arch were installed, each battery consisting of one heat-treating and one annealing furnace set in tandem, with automatic quenching tanks between them. These furnaces were placed in an available building near a disused cupola as shown in the general layout given in Fig. 1. The only change in the design of the furnace as furnished by the maker was to interrupt the continuous slope of the furnace floor some 4 ft. from the discharge end. This horizontal bottom comprised in effect a soaking chamber, permitting a limited degree of freedom of movement of the shells within this portion of the furnace, so that the final adjustment and equalization of heat in the body of the shell might be made by rolling it into such

DESIGN OF QUENCHING TANK

In designing the quenching tank we attempted to incorporate several ideas. First, we wished to reduce to an absolute minimum any inactive bodies of oil within the container during the journey of the hot shell. Second, we expected that the passage of the shell and the operation of the elevator would accomplish a correct circulation of the cooling medium without resorting to other mechanical stirring. Third and finally, we expected to simplify the problem of correctly directing the cool incoming oil and pumping the hot oil from the other extremity of the surface. The guides for lowering the shell into the oil are so constructed that the stirrup or carrier receives the shell base down and releases it at a point where the curvature of the elevator frame pushes the base clear of its support (shown in the general cross section Fig. 3). Lugs on a traveling chain then up-end the shell so that it is finally deposited nose down upon the chain conveyor, which elevates the shell out of the quenching bath. It is driven by a sprocket wheel and delivers the drained shell on the

*As conducted at the plant of the Twin City Forge & Foundry Co., Stillwater, Minn.

FIG. 2. OIL-FIRED HEAT-TREATING FURNACES

rear platform of the drawing furnace. This automatic tank successfully replaced not less than four men at each pair of furnaces at a point where the handling of hot metal is most inconvenient and difficult. The carriers are also provided with pockets to scrape up any scale from the bottom of the tank, dumping it upon a perforated shelf at the top of its travel, where oil is drained off and the scale may be removed.

OIL CIRCULATION AND COOLING SYSTEM

The planning of our cooling system was influenced by a happy combination of natural advantages. Two springs within our premises delivered a constant flow

of oil should be circulated at a rate of 150 gal. per min. in order that the oil might not exceed a temperature of 150 deg. The oil, after being pumped through the cooling coils, emptied into a sump tank, from where it flowed by gravity back into quenching tanks. A separate pipe line and pump were used to empty the oil from the quenching tanks into storage tanks. An analysis of the above data shows the following:

Having a good quenching medium (in this case Houghton Soluble No. 2) a bath of 2000 gal. of oil (roughly 16,000 lb.) circulating at the rate of 150 gal. per min. will dissipate the heat of 80 lb. of steel in the form of a shell, cooling this steel at the rate of 1100 deg. F. per min., and yet keep the oil at a temperature of 150 deg.

FUEL OIL STORAGE AND SUPPLY AND BLAST PIPING

The general drawing Fig. 1 shows location of these items of equipment. The fuel oil was stored in and supplied from a 25,000-gal. cylindrical tank about 25 ft. in height, giving a maximum pressure at the burners of about 9 lb. per sq.in. and an average pressure of about 5 lb. Air was supplied by three No. 45 blowers at about 8-oz. pressure per sq.in. The same drawing shows location of the pyrometer system, which was furnished by the Wilson-Maeulen Co. and gave satisfactory results. Pyrometer wiring was placed in conduit 1 ft. below ground, rising directly alongside the furnace. Indicators and tapalogs were supplied to each row of furnaces.

FIG. 3. GENERAL CROSS-SECTION OF HEAT-TREATING PLANT

of about 90 gal. of water per min. at a temperature of about 45 deg. F. The water from these springs overflowed into wooden cooling tanks and furnished the medium whereby we kept the temperature of the quenching oil at the proper point. In each of these cooling tanks were placed 1200 ft. of 21-in. pipe, the tanks themselves holding some 1200 gal. of water, constantly circulating at the rate of 90 gal. per min., which was the amount of water delivered by the springs above noted. Oil flowed through the piping at the rate of 150 gal. per min. per battery of quenching tanks. Cooled oil was in this manner returned to the tanks at a temperature of about 140 deg. F. when running continuously 24 hr. per day, the cooling water reaching a temperature of 100 deg. F. at the discharge end on hot summer days. In order to cool one shell per minute from 1550 deg. F., the temperature at which it was delivered from the heat-treating furnace, to about 400 deg. F., the temperature when entering the drawing furnace, about 2000 gal. of oil were found to be necessary in the tanks themselves, and this quantity

FUEL OIL AND QUENCHING OIL CONSUMPTION

Our fuel oil consumption was checked regularly and amounted to about 3.5 gal. per hr. per burner; 8 burners were used in each furnace, which gives a fuel consumption of 28 gal. of oil per furnace per hr., or per 60 shell. The consumption of quenching oil was due to its evaporation, plus leakage and the oil film adhering to shell carried out of the tank. This amounted to about 1 gal. of oil per 15 shell, a figure which well indicates the efficiency of our circulating and cooling system.

HEAT-TREATING PRACTICE

After rough turning, nosing-in of forging and rough turning the nose end, the shells are sorted into code lots, and piled or stacked in test lots upon the platform in the rear of the heating furnaces. Respective test lot numbers are stamped on the shell, these lots consisting of 700 pieces selected according to formula. This formula depended upon chemical analysis; after allowing a maximum carbon range of 0.06 per cent,

FIG. 4. OIL-QUENCHING TANK AND CONVEYOR

the maximum variation $3C + Mn$ must not be above 0.25.

The shell is then loaded on the rear platform of the heating furnace and rolled down its inclined bottom by gravity (Fig. 2), a furnace holding about 75. These are withdrawn at the discharge end at a rate of one every minute, thus giving a heating period of 1 hr. 15 min. to reach the required temperature of 1550 to 1575 deg. F. From this temperature they are automatically quenched in the tank described above and illustrated herewith, cooling to about 400 deg. F. before being deposited upon the rear platform of the drawing furnace. Quenched shells are immediately charged, reheated to the proper temperature and withdrawn. The annealing temperature is in the neighborhood of 1220 deg. F., depending upon the carbon and manganese analysis of the steel in that particular lot of shells. The time interval of the heating to this temperature is about the same as in the first furnace, namely, 1 hr. 15 min., although the shell was never withdrawn until a uniform heat was obtained.

Upon withdrawal the shell rolls into a chute which

lands it in an upright position on the floor in front of the furnace, from where it is carried by tongs inserted in the open end of the nose to a cooling floor where it is air-cooled in an upright position.

When cool, two shells are taken at random for testing and the lot is released upon meeting the physical requirements of the specification for a 155-mm. high explosive shell, each shell, however, being stamped with proper heat-treatment mark.

TEST SPECIMEN AND HOLDER

To facilitate the machining of test pieces and in order to avoid threading the ends, we adopted a specimen having ends with spherical shoulders. This is illustrated in Fig. 5, together with details of a holder of my design, which is in fact and principle a double ball joint. The use of this device eliminated side stresses to an extreme minimum and assured automatic alignment with more consistent results than any other holder or type of specimen in general use. Over 50 per cent of our broken test pieces show full cups, and we attribute this fact to the holder in use and its resulting perfect distribution of the tensile stresses.

CONCLUSION

The plant above described has a record of 100 per cent efficiency in heat treating, not a single failure being recorded for the entire contract. The results of our practice are therefore of a most gratifying character, and I attribute our success not only to the personal efforts of the officials and operatives, but more especially to a logically planned and correctly laid out equipment. We, therefore, feel that it may be of some value and benefit to give our methods this publicity, thinking that possibly it may add some useful information to that already available to the man who has to plan and develop an efficient heat-treating department.

Pittsburgh, Pa.

By-Product Coke Oven Operations

Some interesting figures compiled by the War Department comparing the operation of by-product coke oven plants in 1917 with operations in 1918 have been made public in the course of the probe in War Department expenditures being made by a committee of the House of Representatives. The percentage of capacity realized in production in 1917 averaged 88. In 1918 the average was 86.9 per cent. Plants realizing 100 per cent production in 1917 were the Ensley and Tuscaloosa plants of the Semet-Solvay Co., the Fairfield plant of the Tennessee Coal, Iron & Railroad Co., the South Chicago plant of the Semet-Solvay Co., the Sparrow's Point plant of the Bethlehem Steel Co., the Duluth plant of the Minnesota Steel Co., the West Duluth plant of the Zenith Furnace Co., the St. Louis plant of the Laclede Gas Light Co., and the Steelton plant of the Bethlehem Steel Co. In 1918 no plant realized 100 per cent production. In 1918 the per cent of capacity lost on account of no coal was 5.1. In 1917 the capacity lost on account of no coal was 18.75 per cent. In 1918 the toluol per ton of coal averaged 0.31 gal. In 1917 the toluol per ton of coal was 0.27 gal. The amount of ammonium sulphate equivalent per ton of coal in 1918 was 18.07. In 1917 it was 18.95.

FIG. 5. DETAILS OF TEST PIECE AND HOLDER

Industrial Research in Small Establishments*

BY M. E. LEEDS

IN THE past few years, and particularly during the war, research in connection with industry has had much consideration. Most of our large technical societies have devoted sessions to its discussion and have listened to admirable papers on the subject. I hope not to retrace the ground thus covered. In this audience the vital importance of research to our technical industries would not need arguing even if it had not been amply argued. In these discussions research has been considered as something to be carried on in large well organized laboratories, and for that reason possible only for large companies, for associated companies managing a co-operative laboratory or for Government laboratories and the like. I believe that this way of thinking of research unnecessarily restricts it, and that differently conceived its usefulness to small as well as large establishments would become evident and might result in its large extension.

RESEARCH IN A SMALL BUSINESS

The various activities covered by such titles as "Research," "Development" and "Technical Control" are those which should be assumed by a research department in a small business. In order to avoid a cumbersome name for such a department, I want to make a plea for a definition of technical research which some of you may think degrading. Doubtless you are accustomed to thinking of research as an adventure into the realms of the absolutely unknown. A department capable of research in this sense will be possible in a small business only when that business happens to have in it a real scientist. But every technical business (and what manufacturing business is not technical?) is continually confronted with the need of more information than is possessed by its regular staff in regard to processes, characteristics of materials, etc., and if it is to develop realizes that it must find new fields for its product and find new product to sell.

SUGGESTED DEFINITION OF INDUSTRIAL RESEARCH

The most advantageous solution of problems of this character cannot be left to people who are busied with the routine problems of sales and production. They can best be handled by a staff, even if a very small one, set aside for this purpose. I want to suggest that any department having such functions may be called a research department, and that industrial research may be defined for any given establishment as all that class of work which enlarges the technical horizon of the establishment beyond what is necessary for the routine production and test of its product.

You will note that this will make a sharp distinction between a research laboratory and a testing laboratory. I should not want to see a chemical laboratory, however large and elaborate its equipment or however highly trained its staff might be, called a research laboratory if its sole function happened to be routine analysis and check on the product. On the other hand, I should like to see any little room with even a very meager equipment and staff, perhaps only a single individual, called a research laboratory provided the func-

tions of that individual and equipment were solely the improvement of processes, investigation of properties of materials new to the industry, development of new products, etc. And I should want to have it called a research department even if the research be chiefly carried on in libraries or other places for the purpose of bringing information, elsewhere well known, to an establishment to which that information happens to be new.

LARGE CAPITAL NOT NEEDED FOR RESEARCH FUNCTIONS

This conception of research widely recognized might be the occasion for many small industries to start research departments, which these industries now regard as possible only for large capital. In this sense many small industries already have individuals with research functions who have other duties as well and do not clearly recognize their research functions. Under these circumstances both the research and the other work suffer, and as the business develops research does not find the best relation to the work as a whole.

Research, development and technical control merge into each other at many points, and in all but very large establishments can probably best be carried on by a group working under one head. Why attempt lines of demarcation?

CO-ORDINATION OF RESEARCH WITH INDUSTRY NEEDED

In order that research may find its fixed and recognized place in industry it is desirable that it be carefully planned and controlled, and that its results be carefully watched. So far as I know, these two conditions of the successful co-ordination of research with industry have not been discussed. Control in the sense of control of the research in the laboratory after it has been decided on has had discussion, and I do not refer to it, but to the determination of the subjects which shall be investigated in the research department and the decision as to when the research is completed, or, in case it is one that does not lead to satisfactory results, when it shall be abandoned.

For some five or six years this class of decisions in connection with our research department has been made by a committee of which the president of the company, the head of the research department, and representatives of the sales, engineering and production departments are members. This committee, called the research committee, meets once in two weeks, passes on all new subjects for the research department to handle, listens to reports on the progress of the work in hand and passes on recommendations in regard to the conclusion or discontinuance of work. In this way the work of the research department is well co-ordinated with the needs of the business as a whole. As a further factor in co-ordination the head of the research department is one of the board of directors and sits on the executive committee. The research committee has nothing to do with the internal administration of the department, which is left entirely to its own staff.

COSTS SHOULD BE CHARGED AND RESULTS CREDITED

Records of the results of a research department can best be kept by the accounting department. It is just as important to know the cost of research as of any other department, and, as in other cases, the usefulness of the record depends to a very large extent on its sub-

*Read before the Philadelphia meeting of the American Physical Society (Oct. 11, '19).

division. It is worth while to know what investigations contribute to business success and what ones do not.

Some years ago we worked out a plan of determining research cost and making credits to the department which has given us much valuable information. Each investigation undertaken has its cost record kept by the accounting department in the same way that a production order has. We of course do not ask our research men to register their time on a time clock or anything of that kind, but we do ask them to make a memorandum of the work on which they spend their time and turn in to the accounting department once a week a statement of the distribution of their time over the orders running in the department.

METHOD OF DETERMINING RESEARCH COSTS AND MAKING CREDITS

Similarly, expenses and costs of materials are kept, and when an investigation is closed its total cost is determined. If it happens to be one that has to do with manufacturing processes, such as test of new materials, etc., or development of new methods, it is either charged to general expense or to the expense of some particular product. If, however, it is a piece of work which results in the development of a new instrument or product for sale, it is treated in the same way that a new instrument developed and brought in by an

DIAGRAM SHOWING RELATION OF RESEARCH COSTS TO CREDITS

nately. Successful developments accumulate royalties that more than pay for the cost of their research and offset the costs of work that leads to nothing. The diagram shows the relation of annual and accumulated costs of research to the annual and accumulated credits since the department was given a distinct place. In a little over six years the total credits had equalled the total charges and the balance went to the credit side. On the books the account is closed out each year to profit and loss. It is carried forward as a memorandum account only. In the earlier years of the record the total volume of business done by the company was but a few hundred thousand dollars per year.

PLEA FOR DISTINCT DEPARTMENT HAVING ITS PROPER PLACE AS DO OTHER DEPARTMENTS

To summarize, I am making a plea for a conception and organization of research which will allow it to emerge as a distinct department in any growing technical business and take its proper place just as sales, production and accounting do. Any technical business ambitious to grow and render worthy service must in some way avail itself of research. Kenneth Mees and others have pointed out how industry in the past has developed around invention and research, although the distinctiveness of these functions was not clearly recognized, and in many cases they were not directly associated with the business which profited by them. Certainly an enterprise will have a more worthy and normal growth if its need for research is early and clearly recognized, and the research department will more easily find its proper relation to the business as a whole if it is established early and its place and functions are defined. After a business has assumed large proportions, and research functions are distributed in scattered manufacturing and engineering departments, it is difficult to gather them together and co-ordinate them.

THIS CONCEPTION OF RESEARCH NOT VIOLATIVE OF GOOD USAGE

Let me remind those of you who may think this conception of research degrading that the present scientific limitation of the word is modern and confined to the exact sciences. The Century Dictionary gives its definitions in this order:

1. Diligent inquiry, examination or study
2. Laborious or continued search after facts or principles
3. Investigation

and quotes from Cowper

He sucks intelligence in every clime
And spreads the honey of his deep research
At his return—a rich repast for me

so I think the definition which I propose does not violate good usage. Even if it did, would not the possibilities of development and usefulness to industry which this definition allows justify it in the same way that Bryce, in his American Commonwealth, writing of the third quarter of the last century, said that the application of the name "university" to many institutions which were no more than colleges or in some cases high schools was a favorable sign because it showed an aspiration, and that where the aspiration existed the reality would follow? We all know to what a large extent this forecast has come true.

Leeds & Northrup Co.,
Philadelphia, Pa.

outsider would be. The research committee decides how much royalty can properly be charged to the cost of the instrument, and then as each instrument is made the royalty is added to its cost and is credited against its cost account in the research department.

ROYALTIES CREDITED TO SUCCESSFUL DEVELOPMENTS PAY COST OF DEPARTMENT

In that way a continuous record of the usefulness of the research to the business is available. In cases of minor importance it is customary to discontinue credits when the cost has been covered. In cases where new products result they are allowed to run on indefi-

Convenient Chart in Chemical Works

There are any number of ways of assembling data for convenient use in chemical plants, one of which is shown below in the form of a chart with parallel temperature scales and an accompanying table. The Fan-steel Products Co., Chicago, makes the information of easy access throughout its buildings by posting this chart on heavy cardboard in the laboratories, offices, furnace rooms and other locations where it is likely to be needed.

The radial lines in the top half of the scale giving

the colors of metal opposite the corresponding temperature are especially valuable to the practical furnace operator in controlling the heats. At this plant, where a variety of furnaces are operating on the reduction of several of the rare metals, the table with atomic weights and melting points in both Centigrade and Fahrenheit is an added advantage.

Every one admits he knows the conversion factors for temperatures and the atomic weights of most of the elements, but with the chart at hand mental effort is saved and mistakes of memory eliminated.

Synopsis of Recent Chemical and Metallurgical Literature

Continuous Rectification of Crude Benzol.—Mr. A. BARIL gives, in the September, 1919, issue of *Chimie et Industrie**, an interesting description of the Gennevilliers gas works plant for the continuous rectification of crude benzol. The apparatus employed consists of three columns, each provided with its own heating arrangement. The crude benzol enters column A at a. By heating, the first distillate (CS., etc.)

SCHEMATIC ARRANGEMENT FOR THE CONTINUOUS RECTIFICATION OF CRUDE BENZOL

is separated at a'. Here testing apparatus is provided for the purpose of controlling the operation of the column. The partially rectified crude remaining in A enters column B at b. The heating of this column is so regulated that the pure benzene fraction is collected at b'. The product remaining in B passes through c to the column C, where, by a similar procedure, pure toluene is obtained at c'; the residual product, solvent naphtha, being drawn off through d to suitable storage tanks.

Allotropic Nitrogen.—The October number of the *Catalyst*† contains the following discussion on allotropic nitrogen by Dr. HENRY LEFFMANN:

"Until the discovery of the so-called 'noble' gases—the argon group—nitrogen was generally considered by chemists as the most indifferent of the elements as far as properties in the free state are concerned. In contrast with this is the fact that it occurs in nature in many combinations with a variety of elements, and while direct combination is difficult to bring about, many artificial compounds can be obtained by indirect means, among which is the effect of nascent state. Moreover, many of the compounds of nitrogen, however obtained, are not easily decomposed; even the associations with hydrogen and carbon, which from theoretic consideration would seem to be loose unions, are quite stable.

"Many years ago, Professor H. E. Armstrong expressed the view that an allotropic form of nitrogen

characterized by much higher affinity than the common form would be obtained, and it seems that such a form has been discovered. Allotropy is an interesting phenomenon and several striking examples have long been known. Two of the most interesting are seen in phosphorus and oxygen. It is curious that the active and inactive forms of these elements are reversed as to frequency of occurrence. Phosphorus, as obtained in the free state by standard processes, is always the active form, oxygen under similar conditions always the inactive form, with, it is true, often minute amounts of the active modification.

"In 1911 Strutt published in the *Proceedings of the Royal Society* (1911, vol. 85, p. 219), an account of experiments in which nitrogen was subjected to the action of electrical discharges by which new qualities were acquired. The methods and results given in this paper were in outline as follows: Pure nitrogen from any source subjected to jar discharge undergoes a change by which it acquires a short phosphorescence and much increased combining power, combining directly with phosphorus, also with sodium and mercury, at a gentle heat, forming, in the case of last named, an explosive compound. The action on phosphorus is accompanied by the formation of much red phosphorus. (In this is to be noted some analogy to the action of iodine on phosphorus, in which case red phosphorus is also formed.) The modified nitrogen attacks nitric oxide (NO), forming, strangely, nitrogen dioxide (NO₂).

"It attacks acetylene and many hydrocarbon haloids, setting free the halogen and forming cyanogen.

"Strutt's inferences were at once challenged by several investigators, especially in Germany, and for some years a running fire of criticism and counter-criticism has been going on. On Feb. 21, 1918, Strutt delivered before the Chemical Society a lecture on the subject in which he repeated some of his experiments and gave the results of later investigations, especially in the light of the objections that had been made. Among the most important of these objections is that the nitrogen he used was not pure, and that the effects observed were due to the impurities. Oxygen was claimed as the principal impurity. Strutt's lecture appears in the publication of the Society (*J. Chem. Soc.*, 1918, vol. 113, p. 200). He makes the following statements: Pure nitrogen does not give the modification, but traces of many other substances suffice to activate it. Oxygen is one of these, but hydrogen sulphide, ethylene and methane are also active. It seems, then, that a sort of catalysis is essential.

One of the most marked indications of the change in the nitrogen is that it acquires a peculiar glow under the influence of the electric discharge, which persists for a brief period after the discharge ceases. Here there seems to be some analogy to phosphorus, which is a member of the nitrogen group. The subject is interesting, and in the increase of work in pure science, which must soon begin under the conditions of peace, further interesting data concerning it will probably be obtained. Strutt obtained nitrogen mostly from liquid air.

"It is worth noting that Briner and Baerfuss (*J. Chim. Phys.*, 1919, vol. 17, p. 71), in studying the production of ammonia under the influence of arc discharges, did not observe any of the effects on the nitrogen such as Strutt records."

*La rectification continue des benzols. A. Baril. *Chimie et Industrie*, vol. 2, No. 9, September, 1919, pp. 1013-1016.

Recent Chemical and Metallurgical Patents

American Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Process of Recovering Quicksilver From Its Ores.—HENRY W. GOULD of San Francisco, Calif., improves the process of condensing quicksilver vapors which are liberated from roasting ores. The vapors from the furnace are passed through a dust chamber and thence into an inclined conduit made of terra cotta or tile pipe, which acts as a condenser, and the condensed quicksilver is collected from a receiver at the lower end of the conduit. In order to assist in the condensation and, principally, to prevent the precipitation of soot, dust and ash, air under pressure is introduced into this inclined conduit through a nozzle and in the direction of the flow of gases through the conduit. This prevents to a large extent the precipitation of soot, and the condensed quicksilver will readily coalesce. The conduit is of sufficient length to insure the condensation of a large portion of the quicksilver. Brick condensing chambers of the usual form are also provided. (1,315,663, Sept. 9, 1919.)

Process for the Extraction of Sulphur From Metal Sulphides.—MAX HELBIG of Fredriksstad, Norway, obtains sulphur from pyrites by mixing pyrites, apatite, coke and quartz in proportions calculated to correspond to the equation

An enclosed electric furnace to which is connected a condenser is used to carry out the process. (1,315,496, Sept. 9, 1919.)

Method of Briquetting Finely Pulverized Iron Ore.—J. R. H. A. LAMMERHIRT of Hoerde, Germany, has invented a process whereby finely pulverized ferrous-ferrous oxide of iron or magnetic iron ore concentrates may be formed into a briquet. The method consists of adding iron in the form of shavings and finely pulverized ferric oxides or oxyhydrates in a small proportion to the oxide or ore to be briquetted. The process is most efficient if the iron oxide be slightly moist. (1,315,315, Sept. 9, 1919.)

Shellac-Naphthalene Plastic Composition.—In the manufacture of shellac-impregnated paper and cloth for electrical insulating purposes, it has been customary either to mix the shellac with oil, which is a difficult matter, or to dissolve the shellac in wood alcohol. In the latter case, it is found that the presence of wood alcohol, which can be completely removed from the shellac only with great difficulty, lowers the dielectric strength of the product. JAMES P. A. MCCOY of Wilkinsburg, Pa., has found that a mixture of shellac and naphthalene is fluid when heated and forms an excellent impregnating and binding material. The resulting products are flexible, unless heated sufficiently to volatilize the naphthalene. If permanently flexible products are desired, the naphthalene should be replaced by naphthols or other naphthalene derivatives (except chloronaphthalene).

(1,317,204; assigned to Westinghouse Electric & Mfg. Co.; Sept. 30, 1919.)

Recovery of Carbon Bisulphide in Benzene Distillation.—The percentage composition of that fraction of light oil known as "90 per cent benzol" is about 70 per cent benzene, 24 per cent toluene, including a little xylene, and 4 to 6 per cent carbon bisulphide and light hydrocarbons. Attempts to recover the carbon bisulphide by fractional distillation have been unsuccessful, since the boiling points of pentane (the principal light hydrocarbon in this fraction) and CS_2 are so close together, i.e., 37 and 46 deg. C. respectively. By treating this fraction with a halogen in the presence of a suitable catalyst, HERBERT H. DOW obtains a mixture of CS_2 and a halogen derivative of pentane having a boiling point sufficiently above that of CS_2 to make practicable the process of separation by fractional distillation. For example, when chlorine is used pentyl chloride ($\text{C}_5\text{H}_{11}\text{Cl}$; b.p. 160 deg. C.) is formed. (1,317,359; assigned to the Dow Chemical Co.; Sept. 30, 1919.)

Purification of Nitrous Oxide.—Ammonium nitrate is heated to 250 deg. C. in an aluminum retort. The gases evolved pass through a condenser and are then purified by scrubbing with acid potassium permanganate solution, 10 per cent sodium hydroxide and 20 per cent sulphuric acid. All impurities are eliminated, with the possible exception of a trace of nitric oxide, which disappears when the gas is allowed to stand for a period of 48 hr. in an iron or other metallic container. (1,315,354; ANDREW R. WARNER, assignor to Lakeside Hospital, Cleveland, Ohio; Sept. 9, 1919.)

British Patents

Complete specifications of any British patents may be obtained by remitting 25c. each to the Superintendent British Patent office, Southampton Buildings, Chancery Lane, London, England.

Picric Acid.—Picric acid is obtained by nitrating with nitric acid and concentrated sulphuric acid, the dinitrophenol produced by treating 1-chlor-2,4-dinitrobenzene with caustic alkali. (British Patent 9962—1915. L. G. BADIER and L. B. HOLLIDAY, both in Huddersfield; May 14, 1919.)

Calcium Nitrate.—In the production of calcium nitrate by the reaction of calcium chloride on sodium nitrate in solution, the calcium chloride is employed in excess, for instance an excess of 10-20 per cent, and the mixed solution is evaporated, for instance until its boiling point is 130-140 deg. C., and then cooled or allowed to cool, for instance to 60 deg. C., the sodium chloride which separates during these operations being removed; then the solution is diluted, for instance until its boiling point would be about 128 deg. C., and is then further cooled, whereupon calcium nitrate crystallizes out and is washed with water or calcium nitrate solution, and, if desired, may be recrystallized. In recrystallizing, a solution of a boiling point of about 121 deg. C. may be employed, and the mother liquor may be used for washing the crystals first obtained or for diluting the original solution prior to the first crystallization. (British Patent 10595—1915. S. SMITH and AMMONIA SODA Co., Northwich; May 14, 1919.)

Nitrogen Oxides.—For obtaining nitrogen oxides by catalytic oxidation of ammonia, the catalysts employed consist of a mixture of iron oxide, oxide of metal electronegative to iron and reduced but not fused

under the working conditions, such as copper and oxide of an alkaline-earth metal. Hydroxides, carbonates, or other salts may be employed instead of oxides if they are converted into oxides under the working conditions and do not introduce contact poisons. In the examples a mixture of ferric and copper nitrate is precipitated by sodium hydrate or carbonate, and slaked lime is mixed with the washed precipitate, the mixture being molded, dried, and calcined; and a mixture of ferric, copper, and calcium nitrates is precipitated in a similar manner, and the precipitate is similarly treated. (British Patent 10781—1915. E. B. MAXTED and G. R. RIDSDALE, both in Walsall, Staffordshire; May 14, 1919.)

Picric Acid.—In the production of picric acid by sulphonating phenol and nitrating the sulphonation products, the temperature of nitration is not allowed to exceed 118 deg. C., and is maintained for approximately 8 hours. The temperature is preferably maintained at 110-118 deg. C., either by external regulation of temperature or by commencing the reaction at 80-95 deg. C. (British Patent 14367—1915. N. H. GRAESSER and A. W. TITHERLEY, Ruabon, Denbighshire; March 14, 1919.)

Acetone, Acetates and Pyruvates.—Method of making acetates and pyruvates by the action of the mold *Amylomyces rouxii* on a starchy or sugary mash in the presence of an alkaline-earth carbonate. The pyruvates can be converted into acetates by oxidation. The salts can be converted into free acetic acid and then into acetone; or acetone may be obtained directly by the destructive distillation of the salts, air or oxygen being admitted, if desired, to the apparatus in which the distillation is effected. (British Patent 14607—1915. A. FERNBACH, Paris, France, and E. H. STRANGE, London, England; May 14, 1919.)

Explosives.—Methods of preparing explosives which consist in gelatinizing nitrocellulose-nitroglycerine explosives containing more than 50 per cent of nitroglycerine at ordinary temperatures by the addition of 0.1 to 1.0 per cent, calculated on the nitroglycerine content, of aromatic nitro-compounds such as mono-, bi- and tri-nitrotoluenes, mononitronaphthalene, dinitrobenzene, nitroxylenes, and mixtures of these, also "liquid trinitrotoluene." One example contains nitroglycerine 89.8 per cent, soluble nitrocellulose 8.7 per cent, liquid trinitrotoluene 0.9 per cent, and calcium carbonate 0.6 per cent. (British Patent 14656—1915. W. RINTOUL, D. CROSS, and NOBEL'S EXPLOSIVES Co., Ardeer factory, Stevenston, Ayrshire; May 14, 1919.)

Explosives.—Methods of preparing explosives which consist in gelatinizing nitrocellulose-nitroglycerine explosives at ordinary temperatures by the addition of 0.1 to 1.0 per cent, calculated on the nitroglycerine content, of substances of the following classes: Urethanes or esters or carbaminic acid, anilides, substituted ureas, condensation products of glycol and other polyhydric alcohols with aldehydes, homologues of oxanilic ester, and the well known solvents of nitrocellulose such as acetone, acetic ester, and amyl acetate. One example contains nitroglycerine 91.6 per cent, soluble nitrocellulose 7.5 per cent, formamide 0.2 per cent, formotoluidide 0.1 per cent, and calcium carbonate 0.6 per cent. (British Patent 14655—1915. W. RINTOUL, D. CROSS, and NOBEL'S EXPLOSIVES Co., Ardeer factory, Stevenston, Ayrshire; May 14, 1919.)

Personal

Mr. H. R. BEAHM, formerly chemist with the Nitrate Division, Ordnance Department, has been appointed an instructor on the staff of the University of Wisconsin, Madison, Wis.

Lieut. J. H. BECQUE, who has been stationed at the U. S. Chemical Plant, Saltville, Virginia, has received his honorable discharge from the Army, and has accepted a fellowship at the Mellon Institute, Pittsburgh, Pa.

Mr. M. J. BLEW has been appointed assistant professor in analytical chemistry at the University of Louisville, Louisville, Ky.

Mr. JOHN G. BRICKEY has been recently employed as research chemist by the Miner Laboratories, Chicago, Ill.

Dr. C. B. CLEVENGER, recently with the U. S. Soil Survey, has been appointed on the staff of the University of Wisconsin, Madison, Wis.

Mr. FERDINAND P. EGERBERG, a distinguished Norwegian engineer, is at Salt Lake City, on his way to Arizona, where he will study methods of flotation.

Mr. J. B. FROST, formerly with the Semet-Solvay Co., has accepted a position on the staff of the Burgess Laboratories, Madison, Wis.

Mr. SAMUEL HERSCH, formerly metallurgist at the Rear Axle plant of the Maxwell Motor Co., Inc., Detroit, is now connected with the Forest City Machine & Forge Co., of Cleveland, in the same capacity.

Mr. ROBERT M. KEENEY has been retained by the Westinghouse Electric & Manufacturing Co. in a consulting capacity in connection with the development of ferro-alloys now being undertaken by the Westinghouse company.

Dr. S. C. LIND, formerly of the University of Michigan, has succeeded Dr. R. B. Moore as chief of the Colorado Station of the Bureau of Mines. Dr. MOORE has been appointed chief chemist and chief of the Division of Mineral Technology of the Bureau and will be located in Washington, D. C.

Mr. V. W. MELOCHE has accepted an appointment on the staff of the University of Wisconsin, Madison, Wis.

Mr. G. H. MONTILLON has been appointed an instructor in chemical engineering at the University of Wisconsin, Madison, Wis.

Mr. F. G. MOSES has resigned from the staff of the Salt Lake City Station of the Bureau of Mines and is now with The Barrett Co., with headquarters at Salt Lake City, Utah.

Dr. HUBERT L. OLIN, well known to the industry for his work in the chemistry and engineering of fuels, has been appointed chief of the department of industrial chemistry and chemical engineering, Iowa University, Iowa City, Ia.

Mr. J. BENJAMIN PARKER, metallurgist, Salt Lake City, Utah, has accepted a position as flotation engineer with the Interstate-Callahan Mining Co., Wallace, Idaho.

Mr. ROSS PARMELEE has accepted a position with the Redman Chemical Products Co., and will be employed chiefly on research work in Redman. Previous to entering the Chemical Warfare Service Mr. Parmelee was plant manager for the Armour Soap Works, Chicago, Ill.

Mr. FRANK M. SMITH, for many years, in fact since its construction, in charge of the East Helena smelter of the American Smelting & Refining Co., has become assistant director of the Bunker Hill & Sullivan Co., with offices in Spokane. Mr. Smith's wide knowledge of Western ore producers will be utilized by the new company in a vigorous cultivation of the custom smelting business.

Mr. E. GYBON SPILSBURY is on his way to Brazil to study the question of establishing steel works in that country, and expects to be absent three and one-half months.

Mr. E. P. STENGER has resigned from his position as metallurgist for the Sheldon Spring & Axle Co. to accept a position on the staff of Thompson & Black, financial accountants and engineers, Detroit, Michigan.

Mr. JOHN E. VALENTINE has accepted a position as chemist with the Synthetical Laboratories of Chicago, Ill. Mr. Valentine was previously employed in the Chemical Warfare Service, at Edgewood Arsenal.

Current Market Reports

The Non-Ferrous Metal Market

New York, December 12, 1919.

For the last week the copper market has been fairly steady, today's price being 18½¢. for spot. Fortunately, so far as supply is concerned, the curtailment of production because of fuel shortage is offset by exceptionally heavy stocks. With favorable financial conditions the export business would be heavy, as Europe stands in great need of copper. The demand for lead is strengthening as the offerings grow lighter. The market is rising, with brisk business at 7½¢. for spot. Indications are that Great Britain will be a steady buyer of zinc. The New York price was 8.70¢. for spot. Other metals are quoted as follows:

	Cents per Lb.
Aluminium, 98 and 99 per cent.....	32.00—33.00
Antimony.....	9.62½

The Iron and Steel Market

While the union bituminous coal miners began straggling back to work on Thursday, Dec. 11, following the Indianapolis settlement, it is probable that the iron and steel industry will feel the pinch of coal and coke shortage with increasing severity for a week or two after that date. A few steel mills and quite a number of finishing departments had closed from lack of coal at the time of the coal wage settlement, but quite a number of others are likely to be forced to close through their stocks being exhausted. The coal distribution regulations do not contemplate the distribution of more coal than enough to support a 50 per cent operation of by-product coke ovens and of steel mills, and there is no assurance of even such a quantity being actually furnished. A 50 per cent restriction in the production of beehive coke only began as the wage settlement was made, a 25 per cent restriction having been in more or less force for a few days previous, and coke from beehive ovens is usually in transit from one to two weeks, so that with the removal of the coking restrictions entirely problematical the blast-fur-

naces may have a coke shortage until the end of December, and possibly even longer.

SCARCITY OF STEEL

Appearances of steel being scarce have multiplied, but the coal strike itself can hardly be regarded as a cause of steel being scarce, since such observation as can be made rather suggests that the shortage of coal affects the consumption of steel more than its production. Many manufacturing consumers of steel have been closed by the coal shortage or the coal-consuming regulations.

Cases of buyers being in dire need of steel are impressive by reason of the severity of the condition rather than by reason of the tonnages required. Steel is much scarcer among jobbers than among manufacturing consumers, and a rough estimate is that normally only about 10 per cent of the steel produced passes through the hands of jobbers. In some quarters claims are made that mills have been favoring manufacturing consumers to the disadvantage of jobbers.

Fancy prices are being bid for steel, but only for a relatively small proportion of the various descriptions of finished steel turned out by the mills. There is much mention of sales of steel at prices above the March 21 schedule, but it seems certain that in all cases in which any considerable advance has been paid over March 21 prices, say an advance or premium of more than \$5 a ton, the delivery involved is prompt and the tonnage relatively small.

STEEL CORPORATION ADHERES TO SCHEDULE PRICES

The United States Steel Corporation adheres very firmly to its doctrine that steel should not be allowed to advance in price above the March 21 schedule, and it carries its theory into practice, seeing that its unfilled tonnage at the end of November is reported at 7,128,330 tons. This indicates an increase of 655,662 tons during the month, and as the shipments were not far from 800,000 tons the corporation is seen to have sold nearly 1,500,000 tons of its products in the month, in no case charging more than the March 21 price. Nor is the Steel Corporation hopelessly oversold, as some producers predicted recently would be the case if it continued to sell at the old prices, since on a conservative estimate of its prospective output, with gains bringing the output in March up to the pre-strike rate, about 85 per cent of rated capacity, the shipments by the middle of June would be approximately equal to the unfilled obligations now reported.

Several of the large independents are committed to the same price policy as the Steel Corporation, while many of the small independents are seeking advanced prices. As they can furnish little tonnage against fresh sales before about April 1, they are in some instances refraining from selling at all.

Foundry pig iron has advanced in some markets in the week, valley and Philadelphia quotations being up \$2 a ton, but bessemer and basic are unchanged. Quotations on foundry iron now are: Delivered Philadelphia, \$40.10; at furnace, Buffalo, \$39; Cleveland, \$33; Chicago, \$33; Birmingham, \$34. The valley market stands at \$35 to \$38 for foundry, depending on delivery, with basic at \$33 to \$34 and bessemer at \$35.

The Chemical Market

New York, December 12, 1919.

The demand for heavy chemicals remains strong, but trading is light owing to small stocks. Many firms have contracted three or four months into next year, but no further because of the unsettled conditions. The coal shortage which has slackened production will be felt in the market in a few months by buyers of these chemicals. Coal-tar products have advanced in some lines, with a large export demand that is being turned aside in favor of the domestic market. Vegetable oils have been dull, the buyers and sellers each looking at the market from a different angle. Naval stores have been firm, with a drop in some items in sympathy with the Southern market prices.

The crude rubber market has been inactive, except for a few small lot exchanges. Flotation oils are firm, with a

continued brisk inquiry. *Ammonium sulphate* went up and is now quoted at 13-23c. per lb.; there is a scarcity of raw material and the demand at present exceeds the quantity on hand.

The demand on *sodium bichromate* is excessive, and there is very little of it on hand even at 36-45c. per lb.

Formaldehyde and *caustic soda* have moved to the front both in demand and price, formaldehyde being listed at 32-35c. per lb., caustic at \$3.80-3.85 per cwt. Both can be obtained only in small lots. *Glauber's salts* have been active at \$1.50-2.25 per cwt. *Borax* at present is in large demand, increased from 8-8½c. per lb.

Benzol jumped from 25-29c. per gal. to 27-31c., and *toluol* rose from 30c. per gal. to 32c., with large demand for both. *Dimethylaniline* is quoted at 80-85c. per lb., while *aniline oil* can be had in carlots at 32c. per lb., with Japan a heavy buyer. *Alpha naphthol* and *paratoluidine* have been sold out for the first half of next year, with Japan a heavy buyer.

Denatured alcohol jumped to 68-70c. per gal. and no quotations on this item will be given after the first of the year. The demand has been both foreign and domestic and it is difficult to obtain this material, as all available will be used to fill contracts.

Paraffine waxes: Crude match wax (white) 105-110 m.p., is off the market, refined 118-120 m.p. jumped 9c. per lb. against 8½c. of last report, and refined 128-130 went up a cent to 10½c. per lb. This market has been active in exporting to Europe, Japan and South America.

Rosin B-D dropped to a low mark of \$17-17.50 for 280 lb., against \$17.30 of previous quotations, and *rosin E-1* sank to \$17.55-18.25 per 280 lb., from \$18.35-18.95 of last week. *Spirits of turpentine* took a jump from \$16-17 per 280 lb. to \$17-17.50, while *wood turpentine*, steam distilled, went to \$1.63 per gal., compared with \$1.50 of former report.

FERRO-ALLOYS

There have been no new developments recently, market prices in general continuing to rise and demand remaining about the same. Deliveries are a hazard, due to the coal shortage, and some plants have already cut down on their output. Despite these adverse conditions, however, the market continues to step along at its usual pace.

The uncertainty as to what tariff regulations will be imposed on *tungsten* has killed this market. *Scheelite* continues at \$10-15 per unit, and there has been no change in *wolframite*, still quoted at \$7-8 per unit.

Ferromanganese, 78-80 per cent Mn, has been active, with heavy demand and plentiful supply, at the following quotations: English at \$110, domestic \$120 per gross ton. The difficulty of obtaining freightage on manganese ore is holding up this item, which has been in large demand for furnace purposes, at 60-70c. per unit, 45 per cent and over, against 55c., the low market of last week. *Chrome ore*, 48 per cent and over, has jumped from 68c. to 70c. per unit. It is the opinion of some that a new price list will be effective about the first of the year. *Spiegeleisen* is quoted at \$38 spot, \$40 futures, f.o.b. furnace, with demand slightly increasing.

Government prices prevail on *coke*, with foundry nominally quoted at \$7-8 per net ton, compared with last week's quotation of \$5-6. *Furnace coke* has also gone up to \$6-7, against \$4-5 of the previous report. Exporting in this item has fallen off and all available material is being husbanded for domestic use in place of coal wherever possible. A serious shortage of *blanc fixe pulp* is accountable for the rise from \$30-40 to \$40-60 per ton, which is the present quotation. *Barytes white floated* remains firm at \$30-40 per ton, with a large domestic demand which is being filled immediately, the surplus being exported.

An unprecedented demand on *feldspar* has left this item in the position of being quoted nominally at \$13.50-18 per ton, which is the limit set by the Government. It is practically impossible to obtain any of this material, as the supply, which is greater now than it ever has been before, is going to fill up back orders. There has been no change in the general conditions of *talc*, domestic being quoted at \$55-70 per ton, while foreign grades are listed at \$16-60 per ton. *Soapstone* remains firm at \$15-25 per ton.

Chicago, December 12, 1919.

Of outstanding interest in all lines of industry and commerce at the present moment, at least in the Middle West, is the effect of the existing fuel shortage. The chemical industry, as far as production is concerned, is touched to a relatively slight degree. Fuel administrators have ruled that where interruption of a continuous process would result in damage to plant or goods in process, no shut-down is necessary. Chemical processes which generate their own heat are likewise permitted to run, and only those which fall out of these two classes are required to conform to the three-days-a-week ruling.

This is also true in the metallurgical field, so that refiners and smelters are affected only so far as their receipts of ores are cut by the reduction of working time at the mines. Distribution is being affected to a certain extent, many users of chemical products being forced to suspend or operate on part time. The great fertilizer plants in the Chicago district are entirely shut down, but, as no deliveries are being made at this season of the year, the effect of this is almost nil. There is apparently no possibility of the cessation of production lasting long enough to cause any shortage next year.

HEAVY CHEMICALS:—All prices are holding firm, with demand normal. A sudden unexplained shortage has developed in sodium bichromate, which, following its fluctuation between 13c. and 15c. in the last five months, has suddenly shot up to where 32c. would probably be a fair quotation today. Some offerings have been made at 40c., but none has changed hands at that figure. *Ammonium chloride* (white sal ammoniac) is also very scarce and has increased from 13c. a month ago to from 15c. to 16c.

Solid caustic soda is being sold heavily on export orders and the price is now up to about \$4.00 cwt. f.o.b. works. The granulated is bringing about the same figure. Aside from the above mentioned items, the heavy chemical list shows no changes from quotations of recent date.

COAL-TAR PRODUCTS:—Although no changes in quoted prices are seen, a decided stiffening of the market can be felt, due to scarcity of crudes. Spot stocks are very low and producers report output sold, in some cases, ninety days ahead. Continued difficulties with coal supply may lead to serious shortage. As previously noted, current prices are: On benzol, 25c.; toluol, 26c.; aniline oil, 32c. to 33c.; aniline salts, 36c.; salicylic acid, 45c.; benzoic acid, 95c.

VEGETABLE OILS:—Uncertain demand produced a spotty market in vegetable oils here recently. Cotton oil is firm, with crude quoted at 1c. advance, at 18c., and prime summer yellow in barrels at 25c. Demand seems to be slightly in excess of supply. Corn oil is fairly active, still being quoted at 18c. in sellers' tanks. Linseed took a big jump and is over \$2 in less than 5-bbl. lots, \$2.09 being asked. In larger quantities the price is around \$2.04.

Cocanut oil fluctuates between 17½c. and 18½c. for miller grade, with the general trend being toward the higher price, but with demand a little bit weak. Soya bean oil also showed strength, as sales were made at 17½c. in barrels, f.o.b. Chicago, with Pacific coast quotations ruling at 16½c. in sellers' tanks. The high price of silver in exchange with the Far Eastern countries will tend to strengthen greatly both copra and soya oils.

FLOTATION OILS—NAVAL STORES:—The upward trend of pine products, which was interrupted early in the fall, has, under pressure of export sales and exhaustion of stocks of small dealers, resumed its course, as had been anticipated. Turpentine heads the list with a quotation of from \$1.95 to \$1.98, and not much is available even at such figures. Pine tar oil is also higher, .933 pure steam distilled now bringing \$1.60 to \$1.65. Some industries requiring destructively distilled, and that commodity being so short as to be practically off the market, the usual differential between it and the pure has been wiped out, and it is now also quoted at \$1.60 to \$1.65. Rosin has held quiet since the last quotation, F grade still being obtainable at \$19 and W. W. at \$24.50.

NOTE: Owing to an error in proofreading, the price list printed in our last issue was dated Nov. 30 instead of Dec. 6.

Pine tar pitch, bbl.....	200 lb.	8 25	—	14 50
Tar, kiln burned, bbl. (500 lb.).....	bbl.	14 50	—	15 25
Retort tar, bbl.....	280 lb.	15 00	—	
Rosin oil, first run.....	gal.	.86	—	.91
Rosin oil, second run.....	gal.	.88	—	.93
Rosin oil, third run.....	gal.	.95	—	1 12
Rosin oil, fourth run.....	gal.	1 05	—	1 15

Solvents

73-76 deg., steel bbls. (85 lb.).....	gal.	\$0 33 1/2	—	
73-76 deg., steel bbls. (85 lb.).....	gal.	.33 1/2	—	.30 1/2
68-70 deg., steel bbls. (85 lb.).....	gal.	.30 1/2	—	.23 1/2
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	.23 1/2	—	

Crude Rubber

Para—Upriver fine.....	lb.	\$0 53	—	\$0 54
Upriver coarse.....	lb.			.35 1/2
Upriver cauchol bbl.....	lb.	.34 1/2	—	.35 1/2
Plantations—First latex crepe.....	lb.	.31 1/2	—	
Ribbed smoked sheet.....	lb.	.17 1/2	—	.47 1/2
Brown crepe, thin, clean.....	lb.	.46 1/2	—	
Amber crepe No. 1.....	lb.	.49	—	

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.				
Castor oil, No. 3, in bbls.....	lb.	\$0 18 1/2	—	\$0 19
Castor oil, AA, in bbls.....	lb.	.21 1/2	—	.22
China wood oil, in bbls.....	lb.	.22 1/2	—	.23
Cocanut oil, Ceylon grade, in bbls.....	lb.	.18 1/2	—	.19
Cocanut oil, Ceylon grade, in bbls.....	lb.	.18 1/2	—	.19
Corn oil, crude, in bbls.....	lb.			.21 1/2
Cottonseed oil, crude (f.o.b. mill).....	lb.	.18	—	.19
Cottonseed oil, summer yellow.....	lb.	.18	—	.19
Cottonseed oil, winter yellow.....	lb.	.18	—	.19
Lined oil, raw, car lots.....	gal.	1 87	—	1 83
Lined oil, raw, tank cars.....	gal.	1 83	—	1 80
Lined oil, boiled, car lots.....	gal.	1 79	—	1 76
Olive oil, commercial.....	gal.	2 50	—	2 80
Palm, Lagos.....	lb.	.17	—	.17 1/2
Palm, bright red.....	lb.	.16 1/2	—	.17 1/2
Palm, Nigra.....	lb.	.16 1/2	—	.17 1/2
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.23 1/2	—	.24
Peanut oil, refined, in bbls.....	lb.	.27	—	.28
Rapeseed oil, refined in bbls.....	gal.	1 45	—	1 50
Rapeseed oil, blown, in bbls.....	gal.	1 50	—	1 55
Soya bean oil (Manchurian), in bbls., N. Y.....	lb.	.17 1/2	—	.18 1/2
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.15 1/2	—	.16 1/2

FISH

Winter pressed Menhaden.....	gal.	\$1 20	—	
Yellow bleached Menhaden.....	gal.	1 25	—	
White bleached Menhaden.....	gal.	1 25	—	
Blown Menhaden.....	gal.	1 26	—	

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated.....	ton	\$35 00	—	\$40 00
Barytes, of color.....	ton	20 00	—	25 00
Black fire, dry.....	ton	.03 1/2	—	.04
Black fix, pulp.....	ton	30 00	—	50 00
Cacoin.....	ton	16	—	18

China clay (Kaolin), domestic, powdered.....	ton	25 00	—	40 00
Feldspar.....	ton	13 50	—	17 00
Fluorspar, acid grade, lump, f.o.b. mines.....	net ton	30 00	—	35 00
Fluorspar, acid grade, ground, f.o.b. mines.....	net ton	35 00	—	45 00
Fuller's earth, domestic, powdered.....	ton	25 00	—	30 00
Fuller's earth, imported, powdered.....	ton	35 00	—	40 00
Pumice stone, imported.....	lb.	.03	—	.06
Pumice stone, domestic.....	lb.	.02 1/2	—	
Shellite, T.V.....	lb.	1 10	—	1 15
Shellite, D. C.....	lb.			
Shellite, V. S. O.....	lb.			
Shellite, Diamond I.....	lb.	1 00	—	1 05
Shellite, orange, fine.....	lb.	1 25	—	1 30
Shellite, orange, superfine.....	lb.	1 20	—	1 30
Shellite, A. C. garnet.....	lb.	1 10	—	1 15
Shellite, bleached, bone dry.....	lb.	1 10	—	1 15
Shellite, bleached, fresh ground.....	lb.	1 10	—	1 15
Snaptone.....	ton	15 00	—	25 00
Talc, domestic.....	ton	16 00	—	60 00
Talc, imported.....	ton	60 00	—	70 00

Refractories

Following prices are f.o.b. works:

Chrome brick.....	net ton	80-90 at Chester, Penn		
Chrome cement.....	net ton	45-50 at Chester, Penn		
Clay brick, let quality freelay.....	1,000	35-45 at Clearfield, Penn		
Clay brick, 2nd quality.....	1,000	30-35 at Clearfield, Penn		
Magnetite, dead burned.....	net ton	50-55 at Chester, Penn		
Magnetite brick, 9 x 4 1/2 x 2 1/2 in.....	net ton	80-90 at Chester, Penn		
Silica brick.....	1,000	41-45 at Mt. Union, Penn.		

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200 00	—	\$250 00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon.....	lb.	25	—	40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon.....	lb.	20	—	
Ferro-manganese, 70-80% Mn.....	gross ton	110 00	—	115 00
Spiegel Eisen, 16-20% Mn.....	gross ton	33 00	—	36 00
Ferro-molybdenum, per lb. of Mo.....	lb.	3 00	—	3 50
Ferro-silicon, 50%.....	gross ton	85 00	—	95 00
Ferro-silicon, 75%.....	gross ton	150 00	—	175 00
Ferrosilicon, 80%.....	gross ton	45 00	—	60 00
Ferro-tungsten, 70-80%, per lb. of contained W.....	lb.	1 25	—	1 40
Ferro-uranium, 35-50%, of U.....	lb.	7 00	—	
Ferro-vanadium, 30-40%, per lb. of contained V.....	lb.	5 50	—	7 00

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr ₂ O ₃	unit	\$0 60	—	\$0 80
Chrome ore, 48% and over.....	unit	1 00	—	1 25
Coke, foundry, f.o.b. ovens.....	net ton	7 00	—	7 50
Coke, furnace, f.o.b. ovens.....	net ton	6 00	—	6 50
Petroleum coke, refinery, Atlantic seaboard.....	net ton	12 00	—	12 50
Fluorspar, gravel, f.o.b. mines.....	net ton			25 00
Manganese ore, 45% Mn and over.....	unit	.50	—	.75
Manganese ore, chemical (MnO ₂).....	gross ton	60 00	—	70 00
Molybdenum, 85% Mo, per lb. of MoS ₂	lb.	.75	—	.85
Tungsten, Scheelite, 60% WO ₃ and over, per unit of WO ₃	unit	9 00	—	15 00
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃	unit	7 50	—	10 00
Uranium oxide, 96%.....	lb.	2 75	—	3 00
Vanadium pentoxide, 99%.....	lb.	6 00	—	
Pyrites, foreign, lump.....	unit	.17	—	
Pyrites, foreign, fine.....	unit	.17	—	
Pyrites, domestic, fine.....	unit	.16	—	17 1/2
Ilmenite, 52% TiO ₂	lb.	.02	—	
Rutile, 95% TiO ₂	lb.	.11	—	
Carnotite, minimum 2% U ₃ O ₈ , per lb. of U ₃ O ₈	lb.	2 00	—	3 00
Zircon, washed, iron free.....	lb.	10	—	
Monazite, per unit of ThO ₃	unit	42 00	—	

* Government prices.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags.....	bbl.			\$2 80
Lump lime, common, including container.....	300 bbl.			2 65
Common brick, at dock.....	M.			16 00
Yellow pine, 3/4 to 8/8, 20 ft. and under.....	M.			48 00

Yellow pine, 3/4 to 8/8, 20 ft. and under at St. Louis, M.....	M.			40 00
Roofings, tar felt (14 lb. per 100 sq. ft.).....	ton			70 00
Roofings, tar pitch (in 400-lb. bbl.) carlots.....	ton			21 00
Roofings, asphalt pitch carlots.....	ton			34 00
Roofings, asphalt felt carlots.....	ton			63 00
Roofings, slate-surfaced, per roll of 108 sq. ft. carlots.....	ton			2 25
Roofings, slate-finished shingles, 100 sq. ft. carlots.....	ton			6 00
Lined oil, raw in barrels.....	gal.	1 75	—	1 75
Lined oil, 5 gal. cans.....	gal.	1 90	—	1 90
Red lead, dry, 100 lb. keg.....	lb.	13	—	13
Red lead, in oil, 100 lb. keg.....	lb.	13	—	14 1/2
Red lead, dry, 5 lb. cans.....	lb.	13	—	13
Red lead, in oil, 5 lb. cans.....	lb.	13	—	16 1/2
White lead, dry and in oil, 100 lb. keg.....	lb.	13	—	13
White lead, dry and in oil, 25 and 50 lb. kegs.....	lb.	13 1/2	—	13 1/2
White lead, dry and in oil, 5 lb. cans.....	lb.	13	—	13

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2 45	—	
Angles, 3 to 6-in, 1-in. thick.....	100 lb.	2 45	—	
Tees, 3-in. and larger.....	100 lb.	2 45	—	
Plates.....	100 lb.	2 66	—	
Rivets, structural, 1-in. and larger.....	100 lb.	4 20	—	
Rivets, conehead for boilers, 1-in. and larger.....	100 lb.	4 20	—	
Sheets, No. 28 black.....	100 lb.	4 35	—	
Sheets, No. 10 blue annealed.....	100 lb.	3 55	—	
Sheets, No. 28 galvanized.....	100 lb.	5 70	—	

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage. 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c. all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

NOTE—These items were compiled as of Dec. 12, but appear in this issue due to the delay in publication due to the printers' strike.

Connecticut

HARTFORD—The East Hartford District is having preliminary plans prepared for the construction of a 2-story, 62 x 124-ft. school with a 42 x 57-ft. ell. A chemical laboratory will be installed in same. Estimated cost, \$200,000. Johnson & Burns, 174 Bond St., architects.

HARTFORD—The Hartford Fairmont Co., 41 Arch St., will soon award the contract for the construction of an addition to its glass manufacturing plant on Arch St. Estimated cost, \$65,000. Ford, Buck & Sheldon, Inc., 60 Prospect St., engineer.

Illinois

CHICAGO—The Armour Fertilizer Works, Union Stock Yards, has awarded the contract for the construction of an acid plant to Westinghouse, Church, Kerr, Inc., 37 Wall St., New York City. Estimated cost, \$150,000.

EAST ST. LOUIS—The St. Louis Pressed Steel Co., Merchants Exchange Bldg., has purchased a site at 26th and Bond Sts. and plans to build a steel mill. Estimated cost, \$40,000. Fred Key, manager.

WEST FRANKFORT—The Board of Education will receive bids about Feb. 10 for the construction of a 2-story, 94 x 215-ft. school. A small laboratory will be installed in same. Estimated cost, \$200,000.

Indiana

AETNA—The Aetna Iron & Steel Co., Gary, has awarded the contract for the construction of 1-story, 225 x 600-ft. and 75 x 400-ft. rolling mills here, to the Northwestern Bridge & Iron Co., 132nd and Hopkins St., Milwaukee, Wis. Estimated cost, \$350,000.

HUNTINGBURG—The city is having plans prepared for the construction of a sewerage system and a disposal plant. Estimated cost, \$75,000. C. Crossman, Merchants' Bank Bldg., Indianapolis, engineer.

Iowa

DES MOINES—A. Clemens, chairman of the Building Committee, care of Granite Products Co., 725 2nd St., has awarded the contract for the construction of a 80 x 120-ft. factory, for the manufacture of ornamental concrete products, at 8th and Murphy Sts., to J. E. Lovejoy, 1006 Mulberry St. Estimated cost, \$300,000.

Kentucky

BOWLING GREEN—The Atlantic Producing & Refining Co. has purchased and will develop oil properties, also build additions to a plant for refining petroleum and manufacturing lubricating oil and wax. Estimated cost, \$300,000. W. G. Williams, president.

Massachusetts

CAMBRIDGE—The G. H. Dyer Co., (welder) 155 Brookline St., has awarded the contract for the construction of a 2-story, 55 x 100-ft. factory and a 1-story, 30 x 40-ft. boiler house on Brookline St., to F. J. Van Etten Co., 153 Milk St., Boston. Estimated cost, \$30,000.

EAST BOSTON—(Boston P. O.)—I. Young & Co., 85 Borden St., has awarded the contract for the construction of a 2-story, 74 x 80-ft. coppermith factory on Borden St., to Patrick Rich, 67 Byron St. Estimated cost, \$28,000. Noted Oct. 22.

HOLYOKE—The Valley Paper Co., 2nd Level Canal, has awarded the contract for the construction of a 2-story, 50 x 350-ft. factory, to E. J. Kenney & Co., 464 Maple St. Estimated cost, \$70,000.

MEDFORD—The American Radio & Research Corporation, Medford Hillside, will

soon receive bids for the construction of a 1 and 2-story, 140 x 200-ft. factory. Estimated cost, \$90,000. I. F. Bryant, 334 Washington St., Brookline, engineer.

WATERTOWN—The Hood Rubber Co., Nichols Ave., has awarded the contract for the construction of two additions to its factory on Nichols Ave., one 3-story, 32 x 56-ft. and one 1 or 2 story, 60 x 220-ft. to the Aberthaw Construction Co., 27 School St., Boston. Estimated cost, \$80,000.

WOBBURN—The Buckman Tanning Co. is receiving bids for the construction of a sewage disposal plant. Estimated cost, \$20,000. Vaughan & Meyer, Security Bldg., Milwaukee, engineers. Noted Oct. 29 and Nov. 5.

Michigan

BAY CITY—The Columbia Sugar Co., 508 Crapo Block, plans to construct a 1 to 3-story, 800 to 1000-ton capacity factory. A. H. Smith engineer.

Minnesota

MINNEAPOLIS—The Northwestern Glass Co., 219 Second St. N., plans to construct a 4-story, 66 x 162-ft. factory addition on 2nd Ave., and North 2nd St. Estimated cost, \$100,000. Bertrand & Chamberlain, Northwestern Bank Bldg., architects.

Missouri

ST. LOUIS—The Sugar Products Co., 16 Exchange Pl., New York City, has awarded the contract for the construction of a 55,000-gal. molasses storage factory on Vessors & Van Buren Sts., to Murch Brothers Construction Co., Railway Exchange Bldg. Estimated cost, \$125,000.

New York

FREYDENBURGH FALLS—The Farmers Standard Carbide Co. has retained W. E. Moore & Co., engineers, Union Bank Bldg., Pittsburgh, Pa., to prepare plans for the construction of a new carbide plant. The plant will be equipped with a Moore 3-phase carbide furnace, with a 30-ton per day capacity. The 46-ft. water fall will be developed for a capacity of 3700 hp. Crushing, screening and can-making machinery will be installed in same.

GENEVA—The Geneva Glass Products, Inc., plans to install glass-making and glass-handling equipment. Estimated cost, between \$15,000 and \$20,000. Address R. S. Ellinwood, manager.

LONG ISLAND CITY—Dings & Schuster, 510 West 25th St., New York City, have awarded the contract for the construction of a 2-story, 56 x 84-ft. oil factory on 14th St., near Van Alst St., to the Aljon Construction Co., Inc., 51 East 42nd St., New York City. Estimated cost, \$40,000.

LONG ISLAND CITY—The Pathe Exchange, Inc., 25 West 45th St., New York City, is having plans prepared for the construction of a laboratory and studio. Estimated cost, \$70,000. Stone & Webster, 120 Broadway, New York City, architects and engineers. Noted Oct. 29.

THIELS—L. F. Pilcher, State Architect, Capitol, Albany, has awarded the contract for furnishing chlorinating apparatus for the proposed addition to the sewage disposal plant at Letchworth Village, to the Suburban Engineering Co., 15 West 35th St., New York City.

Ohio

ASHTABULA—L. A. Amaden, city engineer, is preparing plans and will submit estimate for the construction of a sewage disposal system.

CAREY—The Carey Tire & Rubber Co. has awarded the contract for the construction of a 3-story, 80 x 160-ft. rubber factory, to C. N. Dennis, Tiffin. Estimated cost, \$150,000.

CLEVELAND—The Glidden Varnish Co., West 110th St. and Berea Rd., has awarded

the contract for the construction of a 3-story, 60 x 100-ft. factory on Berea Rd., to the Hunkin-Conkey Co., Century Bldg. Estimated cost, \$600,000.

GREENVILLE—The city plans to construct a filtration plant. Estimated cost, \$135,000. G. A. Johnson Co., 150 Nassau St., New York City, engineer.

Oregon

RICHLAND—The Town Council will soon award the contract for the construction of a waterworks system, including four miles of 8-in. supply main, steel or iron pipe, 50 water meters, connections, a 125,000-gal. per minute filtration plant, one mile of distributing system, etc. Estimated cost, \$35,000. L. C. Kelsey, 410 Selling Bldg., Portland, engineer.

VALE—The Idaho Mutual Sugar Co. has purchased 4000 acres of land for beet growing and plans to build a 2 or 3-story, 500-ton daily capacity sugar factory on Dead Ox Flat. Estimated cost, \$1,000,000.

Virginia

ORANGE—The city will soon award the contract for the construction of cast iron water mains from the town to the Rapidan River; also for the installation of a filtration plant and pumping station. Address A. J. Harlow, mayor, Sayville & Claborn, 7th and Main Sts., Richmond, engineers. Noted Oct. 29.

West Virginia

PARKERSBURG—The Vitrolite Co. has awarded the contract for the construction of a 1-story, 200 x 300-ft. factory addition, to Flote & Logie, Parkersburg. Estimated cost, \$300,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a meeting in St. Louis from Dec. 26 to Jan. 1.

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23-26.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold meeting in Boston, April 8, 9, and 10.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York, Feb. 16-19.

THE AMERICAN PHYSICAL SOCIETY will hold meeting in St. Louis from Dec. 26 to Jan. 1.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

THE MINING AND METALLURGICAL SOCIETY OF AMERICA will hold a meeting in New York Jan. 13.

Industrial Notes

MUNN & Co., patent attorneys, Washington, D. C., Chicago and New York, announce that Mr. L. A. Paley has entered their office as their attorney.

HAMILTON & HANSELL, INC., 13 Park Row, New York City, will from now on dedicate its entire business to metallurgical and general engineering work. In conjunction with domestic work, it will carry on development of foreign patents and enterprises. A separate company, namely, the American Transmarine Co., has taken over all the general export and import business not relating to engineering. For the past 5 years Hamilton & Hansell, Inc., has been licensee and builder of the American Rennerfelt electric furnace for ferrous and non-ferrous work, and has also designed a number of electric reduction and electrochemical plants. The following contracts were closed during the last three months: One 1000-lb. 200-k.v.a. Rennerfelt furnace, for special iron, A. M. Byers Co., Pittsburgh, Pa.; one 20-k.v.a. Rennerfelt special furnace, for electric steel, Alfa, General Chemicals Co., Perth Amboy, N. J.; one 4-gross-ton, 1200-k.v.a. Rennerfelt furnace for tool steel, for export to Sweden, one 300-lb. 100-k.v.a. Rennerfelt furnace for aluminum alloys, Hauch Machine Tool Co., Springfield, Mass.; two 1000-lb. 200-k.v.a. Rennerfelt furnaces, for high speed steel (one), U. S. High Speed Steel & Tool Corporation, Albany, N. Y.

Volume 21

New York, December 10-17, 1919

Number 14

Out of The Woods

AS NOTED in our 11th issue, published December 8, but dated October 29-November 5, the problem before us at that time was to "catch up," and the best way out into the open then apparent was indicated. Since that date there have been printed, including the present issue, three double numbers in slightly more than two weeks, so that the present issue is mailed on the regular publication date. However, there still exists one issue not printed, which will be consolidated with the last number of the year, mailed one week hence. Thus it is that starting in with the New Year, CHEMICAL & METALLURGICAL ENGINEERING will be square with the world, and can buckle down to the long road ahead, to its function as a weekly technical journal advocating the best possible engineering practice in applied chemistry.

Every Engineer A Counter Propagandist

THE philosophic GOETHE lived in days when Germany was poor in pocket, but great in mind. And when, in "Faust," he desired to represent in *Mephistopheles* the spirit of evil, he made him the spirit that denied all things. He took the ecclesiastical devil and made him a devil of everyday life; for the spirit of evil of our day and generation is that which denies. Let us consider the subject for a minute or so.

The real trouble with labor just now is that in following KARL MARX it has come to the conclusion that labor is the true and sole source of all wealth, and that the representatives of capital are, in effect, the receivers of stolen goods; that they have got control of the machinery of laws and justice, and that the only way for labor to come into its own is to strike, and strike, until the administrators of capital are driven to cover, leaving capital behind them. Then labor will take this and enjoy its fruits. It may not sound reasonable, but such is the gospel.

Now if, in working for a man, a laborer believes his employer to be, in effect, a receiver of stolen goods, and therefore in criminal possession of his property, he cannot have faith in such a man, nor will he want to see him prosper. As a worker he will do as little as possible. If he belongs to the I. W. W., or is a Communist, or a Socialist of the radical wing, these are likely to be the views he holds. And the propaganda of these organizations, which he gets and the rest of us do not, teaches that government and courts are based upon an organization of capital; that they are founded on false premises, and should therefore be overthrown.

The plan is to supplant the government by a "proletariat dictatorship" until a government of and by workers is established.

This is the doctrine that foment strikes, and represents profit-sharing, or any kind of internal organization of workers. The control of workers, it is held, should be from the outside, so as to destroy the minions of capital who are in control of industry.

Among many agitators this doctrine has become an *idée fixe*, and they can no more be argued out of it than a gamecock can be reasoned into leading a life of amity with his Plymouth Rock brethren in a barnyard. They don't want to be argued out of it, and they have a string of verbiage in reply to argument that would confuse a Philadelphia lawyer. Their business is rebellion; rebellion is their normal state, and if there were to be brought about the general strike which they are always trying to initiate, or the rebellion of the proletariat which they constantly urge should ensue, they would be quick to arise in opposition to it. They have no sense of system or of order, and whoever establishes system or order becomes their enemy thereby. This they constantly prove, even while denying it. Their policy is destructive, but never constructive. They hold the Russian Soviets to be a glorious success, and declare that those of us who do not agree with them have been misled by the false reports of a capitalistic press.

Not all our workingmen are built that way. Many are ambitious, and want to gain property for themselves; they want to own property, in time, and to be protected in their ownership. But we are neglecting our opportunity if we do not reason with them, and strive to keep their minds open while the apostles of anarchy are seeking with every persuasion at their command to close them. We must go out and do this thing ourselves, and we must put heart into this self-imposed task because men in revolt will not listen to paid pacifiers. We cannot trick them into assent, either, because trickery, like murder, will out. Then it breeds dissent. To accomplish this is difficult, and often disheartening, but it is the only way out. Industry requires eager and enthusiastic labor rather than cheap hands, and unless those of us engaged in industry become teachers of good citizenship by example as well as by precept, our industries are doomed. Neither invention nor astuteness can meet the deadening influence of denial and hate which thousands of agitators are preaching in nearly every industrial center, and which, if they succeed, will bring about such a reign of terror and confusion as to kill freedom—freedom for the individual man and woman. Not only will it put an end to legitimate personal opportunity, but it will utterly destroy free government.

Oil Shales and The Merchant Marine

THE United States Shipping Board now has control of a merchant marine of about 11,000,000 net tons—next to England's the largest in the world. This is the nucleus of a fleet of American-made and American-operated ships that may well re-establish our easily lost supremacy of the seas. Advent of coal-burning steamships, combined with England's vision in establishing coaling stations under the British flag throughout the world, was a potent cause of our downfall; the advent of oil-burning steamships and the vision of our Government in establishing fuel-oil stations throughout the world under the American flag will at least enable us to maintain our present maritime position. Coaling stations can be no more than 4000 miles apart, that distance being about the steaming radius for coal-burning ships, but an oil-burning vessel can steam 10,000 miles without refueling—and our established stations are within that distance apart. St. Thomas and the Azores in the Atlantic, Bizerta in the Mediterranean, the Philippines and Hawaii in the Pacific and Colon on the Isthmus assume added importance in this aspect of the situation.

If fully taken advantage of, the operation of an American Merchant Marine will be of incalculable value to the nation and should assure for our exports a freedom from foreign interference. All this provided the source of the fuel oil as well as the fueling stations be under the control of our Government to the extent of being located on American soil. Obviously, in time of danger it would be necessary for us to control absolutely the productive areas as well as the storage supplies and points of distribution.

The problem of supplying these fueling stations in the future is of considerable concern to those who are in position to understand the consequences should a serious shortage develop. Our petroleum fields have a limited length of life; it seems to be the consensus of opinion on the part of oil geologists that the probability of discovering further large oil fields within the boundaries of the United States is remote. We cannot be dependent upon oil from fields that are under the control of other nations in time of war, and for economic reasons it is not desirable in times of peace. By a process of elimination one arrives at the eventual resources of the nation—liquid fuel from solid carbonaceous material—peat, lignite, coal, bituminous sandstones and oil shales.

The Navy Department with commendable vision has had large tracts of oil-shale lands withdrawn from entry in order to establish a reserve for the future, and with this end in view is co-operating with the Bureau of Mines in the development of methods whereby the oil in this shale can be made available for use. The Southern Pacific Railway Company is also co-operating with the Bureau of Mines along these same lines, realizing the importance of a source of fuel-oil supply along its right-of-way independent of the California petroleum fields. It would also seem desirable that the Shipping Board investigate the feasibility of developing a supply of fuel from oil shales.

It will be necessary to conduct extensive and costly experiments before the technical problems connected with the distillation of oil from shale and the recovery of the by-products will be economically solved. It is certain that a profitable shale-oil development will require large capital expenditures, and successful installations must be able to handle large tonnages from deposits that

are known to be of sufficient magnitude to assure a long life to the enterprise. Potentially the oil-shale deposits in our Western States are a national asset of first importance, but their development should proceed along rational lines and should be undertaken only by those thoroughly cognizant of the financial and technical magnitude of the problems involved in the establishment of an oil-shale industry. Wildcatters are ready, but enormous monetary loss can be avoided by some scientific agency approaching the problem with the wide technical view necessary for success.

Reconstruction Still Lags

IN A material way the greatest loss occasioned by the prosecution of the war was the curtailment in construction work. In normal times the world is continually building highways, railroads, factories, hotel and office structures, dwelling houses, power plants, and such things. The war greatly curtailed this activity, and thus there was a great halt in progress. Undoubtedly, taking the world as a whole, that loss was a greater amount than the loss by direct destruction.

During the year following the Armistice, however, such work has not only not been prosecuted with greater than normal vigor, but there has not been even the normal amount of such activity. The war, in other words, continues to retard progress. This loss has been world wide. It is not confined to the belligerent countries. Sir GEORGE PAISH was right when, in February, 1916, in an article in the *New York Sun*, he said: "The idea that the United States is deriving any advantage whatever from the war is a complete delusion. All that is happening to the advantage of your country is that it is suffering less than the belligerents as a result of this titanic conflict."

He was right. What appeared to be a gain during the period before the United States entered the war was simply that the other countries were losing more than we, and thus we came to occupy a better position, simply relative to them. For instance, we made shells for Great Britain, for which that country now owes us money, and eventually it will pay us interest at a low rate. If instead of making shells we had drained swamp lands or built hydro-electric plants, we would now have the improvements and they would be paying us much larger dividends than the interest from Great Britain will amount to when it is paid, for just now we are not even getting paid hard money for interest, we are actually engaged in funding the interest. When the United States entered the war the case was made so much the stronger.

It is true that the war added much to the knowledge of the world. It developed aviation, for instance, and gave the chemical industries, particularly in the United States, a great deal of information that they did not have prior to the war. Knowledge, however, is useless if not applied, and to apply most of the knowledge contributed by the war, construction is necessary. Construction is retarded by effects of the war, high prices, unwillingness of men to work hard, but possibly more than any other one thing, to the growing spirit of distrust and lack of confidence which is arming each man even against his friend and neighbor. Yet there are some bright sides to the situation.

Industry must stagnate when it has no improvements to make, when manufacturers have no ideas whereby they could embark in fresh ventures. There is an ample store of ideas. It is dangerous for too much construction work to be indulged in. A favorite theory as to industrial depressions is that they are caused by there having been too much construction work, too much capital having been converted from liquid to fixed form. Present conditions, as to costs and the unwillingness of men to work hard and efficiently, tend to discourage construction work, and while some is being done, enough to furnish all the work that men are willing to do, there is a great deal of work that is held in abeyance. This can be done in the future when men are willing to do it. One cannot possibly see at the present time any danger that construction work will be carried too far. In eight years after the Civil War we doubled our railroad mileage, building 35,000 miles, and then found we had built more railroad than we could patronize to a sufficient extent to make it pay well. Now we are not building railroad at all and are building scarcely any rolling stock.

We are, however, building tremendous numbers of automobiles and we must be making enormous numbers of silk shirts, judging by the stories in circulation as to the way workmen are buying them. This is not the conversion of liquid capital into fixed capital, to produce in some later year an industrial depression. It is converting money into something that is very far from being fixed. By many all of this extravagance is regarded as a bad thing, as doubtless it is, but for the long-range effects there are worse things. If it is wrong, the punishment will come quickly instead of being deferred, as it is when too much construction work is done. It is better probably for the war still to be retarding our progress than for it to leave a stimulus to cause us to make progress at a greater rate than we can safely stand over a period of years.

Books Beat Bullets

ABRAHAM LINCOLN'S homely philosophy endeared him to his contemporaries, and now has exalted his memory to that of an immortal purely because it matched his life and was based on careful thinking from a fundamentally sound set of principles. Therefore many of his sayings are independent of time and place—to the point then, they still apply to modern problems, and will be quoted for guidance again and again.

How aptly significant are the words: "Rattlesnakes and panthers and Indians know the fighting game and have weapons for the purpose, but this sort of fighting will never make the world a better place to live in. If the world ever gets to be the kind of a place you ask God for when you pray, 'Thy kingdom come,' it's coming by brains and hearts instead of claws and fangs. You can't shoot sense nor religion into a man any more than you can beat daylight into the cellar with a club. Take a candle in, and the thick darkness disappears; just so give the people knowledge and their ignorance and intolerance and other devilment will disappear. I haven't lived so powerful long yet, but I have lived long enough to make up my mind that for the good of all mankind, books beat guns."

Chemical and Physical Constants

RESOLUTIONS were adopted at the Savannah meeting of the American Institute of Chemical Engineers cordially supporting the committee of trustees organized to undertake the business arrangements for the great work of establishing, bringing together, editing and publishing these enormous compendia of fundamental data.

Their first step is to raise \$200,000, and they are entitled to the earnest and hearty support of American chemical industry in the effort. These tables are a matter of everyday interest in the solution of technical problems. Let us cite an example of their practical value. A great shipment of fluid merchandise was about to be made in tank cars. The managing director was on the job, and he asked the man in charge how full he was making the tanks. "Filling 'em right up," said he. "Well, stop it," said the manager. "What is the cubical expansion of this material?" Nobody knew. "Look it up in Landolt and Börnstein." It was not given there. "Then make a determination in the physical laboratory." This was done, and found to be about ten times that of water. The whole shipment might have been lost by a warm wave if this constant, which is nowhere given in the literature of the subject, had not been determined.

It has been said in Germany many times that their scientific literature lost them the war. In so far as we encouraged the Germans to publish everything we needed in their own way, and in their own language, this is true. When the war came on there was no less than a scramble on behalf of the Army, Navy, Airplane, Medical, Shipbuilding and Explosive Departments and Commissions, the National Research Council, the Council of National Defense, etc., all wanting Landolt and Börnstein's Tabellen—and hardly enough to go around!

Now, the Landolt and Börnstein tables are inadequate and incomplete, and in many respects incorrect. They are the best there are that are published and available, but they are not good enough for the needs of intensive chemical research and industry. There's no use trying to introduce any pseudo-practicality by calling only for compendia that are "likely" to be needed. Who knows what constants he will need before he knows his problem? And they must be right. A guess or an "approximate conclusion" as to the melting point of tungsten, or silica, was good enough until tungsten came into use, or firebrick to be really studied, and then the record was found to be wrong!

The time has come, too, when the English language should be made a great medium of expression for chemistry. Many of our chemists coming along and here already do not speak or even read German. They are not of necessity ignorant for that reason. And again, in the Inter-Allied Council and the International Research Council, the United States has agreed to do this thing. It is not a problem for the Senate to wrangle over, there is no politics in it, and the pledge was given by our own duly accredited men of science. Let's go to it, and give these trustees the help they need. They are giving their time and energy without charge. They consist of HUGH K. MOORE of Berlin, N. H., chairman (from the Chemical Engineers); JULIUS STIEGLITZ of Chicago University (from the American Chemical Society), and EDWARD P. HYDE of Cleveland (from the American Physical Society).

Western Chemical and Metallurgical Field

Notes on Magnesite Refractories

THE continuation of domestic dead-burned magnesite as the source of supply of the raw material for the refractory magnesite industry in this country depends upon the clarification of prevalent ideas regarding quality, supply, and cost to the consumer per unit of finished product, contingent upon the use of this material. Few of the factors pertinent to the manufacture of brick of excellent quality are understood by all concerned; the situation has been and is being obscured by conflicting statements and propaganda.

Some consumers assert that brick made from domestic dead-burned magnesite are of an inferior quality; this is regrettably true of a large proportion of the brick manufactured in this country until recently. The unreliability of the brick, together with the high prices which obtained during the war, added materially to the cost of a finished product, decreased furnace efficiency and therefore reduced output. The manufacturers of the brick gave quality of the raw material as the cause. The users had to have the brick regardless of quality or cost. The producers of dead-burned magnesite delivered a dead-burned material which did not produce a brick of good quality when used under the same manufacturing conditions as was the Austrian dead-burned magnesite; both the producer of dead-burned magnesite and the brick manufacturer were more concerned with meeting demands for brick than with the idea of establishing the industry on a quality basis.

QUALITY THE IMPORTANT FACTOR

The question of supply is of less importance than that of quality; there were times of acute shortage during the war, but this condition did not obtain for long. Quite recently the situation again became acute. The producers of dead-burned magnesite had ceased operations, there being no demand for their product. The brick manufacturers had expected Austrian dead-burned magnesite to come in as return ballast in food ships; this supply did not materialize. Users of brick allowed their stocks to become depleted in expectation of lower prices. This combination of circumstances suddenly became apparent, and it was necessary for one of the western producers to re-establish operations, thereby relieving the situation. This answers the question of immediate supply. The reserves in sight are claimed by the U. S. Geological Survey to be ample for at least twenty years at the present rate of consumption.

QUESTION OF MANUFACTURING TECHNIQUE

The production of a magnesite brick of excellent quality is as much a question of manufacturing technique as it is of raw materials. Brick produced from dead-burned Austrian magnesite was the result of twenty years development from this particular material, and the brick makers in this country had established their manufacturing methods around this one source of supply. When it became necessary to manufacture brick from dead-burned domestic magnesite, the unreliable and non-uniform brick produced were admittedly caused by the difference in raw material. The production of an inferior article continued until the producers of dead-burned magnesite had imitated as nearly as was possible the Austrian dead-burned product, producing a satisfactory material, which was accomplished by the

addition of iron oxides to the ground magnesite before burning, and the manufacturers had modified their manufacturing methods by alterations suitable to the domestic dead-burned magnesite. The function of the impurities associated with the Austrian mineral were not thoroughly understood, but the addition of iron to the domestic minerals was found to improve quality. California deposits, from which the supply was first obtained, are of the amorphous variety of magnesite, the Austrian deposits are of the crystalline variety; this difference was also thought to be an additional cause for the unsatisfactory product. The development of the crystalline deposits in Washington occurred during 1917. By this time the functions of iron, silica and lime were better understood. Brick has been made, within the last year and a half, from these deposits as well as from the California deposits that are said to be in every way the equal of any produced from the Austrian.

ADAPTABILITY OF AMERICAN MAGNESITE

The crystalline or amorphous nature of the magnesite has no effect on the quality of the product resulting from the burning operation. Either variety is converted into amorphous magnesium oxide at the temperature required to liberate the carbon dioxide, or at about 800 deg. C. The refractory properties of the brick are due to the formation of the crystalline variety of magnesium oxide, which is the mineral periclase. The structural properties of the brick at furnace temperature are due to the size of the periclase crystals, to the completeness of crystallization, to the nature and amount of bonding material and to the nature and amount of other impurities such as iron, lime or silica, which may be associated with or added to the magnesite mineral.

The iron associated with the Austrian magnesite, as carbonate, and that added to domestic magnesite, as iron oxides, acts as a catalyzer in producing periclase, increasing the rate of formation and lowering the temperature necessary for complete crystallization. In order to produce a uniform product the iron and magnesite must be intimately associated. In the Austrian magnesite, this has been done by nature; with the domestic, fine grinding and intimate mixing are essential. Silica reacts with iron oxides to form silicates which are fluid at the temperature required to produce a dead-burned product, between 1450 and 1500 deg., and assist in the uniform distribution of the iron throughout the amorphous magnesite. Iron, silica and lime must not be present in amounts deleterious to the production of brick designed to have maximum strength at furnace temperatures. Silica, and iron combined with magnesite, act as a bonding material for the periclase crystals and the physical characteristics of brick can be controlled by the amount of silica and iron in the dead-burned magnesite used in their manufacture. Finally, press molding and correct kiln operation must be an adjunct to a satisfactory raw material if a superior brick is to be produced.

It appears to be a reasonable claim and an established fact that brick can be produced from domestic dead-burned magnesite, in which the amount of lime and silica has been controlled by selection and blending, that are equal or superior to any yet produced from the Austrian product. Looking into the future, the users of magnesite brick may demand and receive a superior article from the brick manufacturers, and therefore expect a reduction in the cost of this material per unit output.

New Jersey Chemical Society

A MOST interesting program was provided for the December meeting of the New Jersey Chemical Society, which was held at Stetter's Restaurant, Newark, on Monday evening, Dec. 8.

MANUFACTURE OF PAINTS AND VARNISHES

Dr. E. C. HOLTON, chief chemist of the Sherwin-Williams Co., commented briefly upon a series of motion-picture films showing some of the products made by this company. The manufacture of lead-zinc paints was illustrated in considerable detail, from the mining of the mixed sulphide ore through the concentrators and roasters to the mills which grind the pigment in oil, and the filling machines which deliver the product ready for shipment. Numerous views of the different plants of the company served to convey an idea of the magnitude of the organization.

THE LAKE ASPHALT INDUSTRY

The paper on the lake asphalt industry, delivered in the absence of Mr. C. N. Forrest by Mr. J. S. MILLER of the Barber Asphalt Co., proved to be the feature of the evening. Mr. Miller discussed the nature and occurrence of natural asphalt in the lakes of Trinidad and Venezuela. The importance of colloid chemistry in the study of bitumens led the speaker to a general discussion of the colloidal state of matter. Research has demonstrated that the difference in physical properties between natural asphalt and artificial asphalt (obtained as a residue in the distillation of asphaltic-base petroleum) is due to the presence, in the former, of colloidal particles of clay. Owing to their extremely small size, the surface energy of these particles is enormous. This accounts for the superior binding powers of the natural asphalt. Attempts to prepare similar colloidal suspensions of clay in artificial asphalt have not met with perfect success, although progress is being made in this direction.

It is interesting to note that the ultramicroscope proved invaluable in this research, since the particles are too small to be visible in the ordinary microscope. The supernatant liquid from solutions of natural asphalt in benzene which have been allowed to stand undisturbed for six months shows the Brownian movement of the colloidal particles when viewed under the ultramicroscope. Through unlimited perseverance, the research department was able to secure (for the first time) motion-pictures of the Brownian movement. The difficulties encountered in the preparation of this film are readily appreciated when it is considered that the particles to be photographed are smaller than the silver bromide grains in ordinary film. The remarkable results obtained brought forth hearty applause from the members and their guests.

Other films showed the mining of asphalt at the Venezuelan lakes, the necessity of re-mining from the steamer hold, and the making of asphalt roofing.

FILTER PRESSES AND FILTRATION

Mr. C. L. BRYDEN of the United Filters Corporation described the various types of filter presses placed on the market by this company, emphasizing his points on constructional detail by a series of lantern slides showing the Kelly and Sweetland pressure filters and the American continuous filters from many points of view and under various operating conditions.

Priestley's Home Purchased by Penn State Chemistry Alumni

THE original home and laboratory of Dr. Joseph Priestley, the famous chemist who discovered oxygen in 1774, which is located on the banks of the Susquehanna River at Northumberland, Pa., was purchased recently by graduate chemists of the Pennsylvania State College, who plan to move it to the campus and make it a lasting memorial to the great scientist.

Upon learning that the Priestley homestead, which was built in 1794-96, was to be put up at public auction, the Penn State chemists sent as their representative to the sale Dr. G. G. Pond, dean of the School of Natural Science at the College. He was successful in making the purchase, and thereby was able to announce that the old historic mansion would be preserved in its original lines.

Expert architects from the College will at once make the necessary surveys preparatory to the work of moving the Priestley home from Northumberland, Pa., to the campus at State College, a distance of about 60 miles. While the purchase of the home has been made by Dr. Pond for the Penn State chemistry alumni, who are scattered to all parts of the country, funds for its removal and erection on the College campus will be supplied by an as yet unnamed donor. Actual work of removal will probably be started in the spring. The reconstruction on the College campus will be along the old architectural lines, but modernized and adapted to some suitable use by the School of Natural Science, according to present plans.

Dr. Priestley's career as a scientist in the last half of the eighteenth century was one that has established him as one of the greatest in history. He is credited with the discovery of oxygen and many of its properties in his laboratory in England in 1774. About the same time he discovered ammonia and hydrochloric acid, and a year later, in 1775, he was credited with the discovery of sulphurous acid gas. Within another year he found nitrous oxide (laughing gas). His discovery of nitric oxide dates from 1772. A large amount of his experimental work was conducted after 1780 in Birmingham. He was a noted dissenter in religious views and was persecuted in England for his Unitarian teachings and activity. His house in Birmingham was mobbed and all of his chemical and physical apparatus destroyed. He was made uncomfortable in London, and, not being sure of his life, he came to America in 1794. His sons had preceded him. He settled at once at Northumberland and built the Priestley mansion there. He continued his experiments there until his death, in 1804. He was buried at Northumberland, and the house and grave have been visited by interested persons from all parts of the world.

In 1874 a large number of chemists gathered there to celebrate the 100th anniversary of the discovery of oxygen. These chemists formed the nucleus of what is now the American Chemical Society. One speaker on that occasion said: "Of the most important gases known at present, we owe nearly three-fourths to Priestley."

Dr. Priestley was a prolific writer, quite as much on religious as on scientific subjects. He was a vigorous and incisive teacher and preacher. His political principles found no favor with the Adams administra-

tion, and it is said that at one time he was threatened with expulsion from the country. However, he was a very ardent supporter of Jefferson, and was offered the position of Congressional chaplain, which he refused. His discoveries in chemistry would have established the fame of half a dozen ordinary workers, yet in his own opinion most of his results were accidental. One of the most important discoveries that he made at Northumberland was the fact that plants inhale oxygen in sunlight, and that oxygen turns dark venous blood red.

Beverage Exposition Features Chemical Equipment

THE Beverage Exposition and meetings of four associations held simultaneously in Chicago, Nov. 1 to 9, was an occasion of the largest gathering of the soft-drink industry representatives ever witnessed. The people engaged in this business have been very much in a quandary as to what the future holds, and this series of meetings was projected to help clarify the situation. This was the first show of its kind, and beyond all expositions that have previously been witnessed at the Coliseum was the most befitting combination of attractions for the general public on one hand and of deep interest to the industrial visitors on the other.

The industrial exhibits were the main feature of the exposition. In addition to the bottling machines, bottles and bottle washing machines, trucks, soft drinks, cereal

FIG. 1. RAPID CIRCULATION EVAPORATOR

beverages, soda fountain supplies and specialized equipment peculiar to the industry, there were many items of interest to the chemical business.

EVAPORATING AND DE-ALCOHOLIZING APPARATUS

A special type of evaporator, known as the vertical rapid circulation evaporator, was shown by the Buffalo Foundry & Machine Co. Fig. 1 illustrates the apparatus in section. It employs the high velocity principle, thus keeping the tubes clean—an essential point in handling food products. It is particularly adaptable to the con-

FIG. 2. STERILIZING PLUTO WATER BY ULTRA-VIOLET RAYS

centration of thin liquids of foamy nature, or organic solutions which should be exposed to heat for only a short length of time. This makes it suitable for malt extracts, fruit juices and de-alcoholizing beers and wines.

Vacuum evaporators for the removal of alcohol from fermented beverages without impairing the taste or character of the product were exhibited by the Hercules Engineering Corporation, and Joseph Schneible. The latter also showed sections of larger continuous stills capable of producing in one operation alcohol up to 192.5 proof, the residual beverage having zero alcohol content.

FILTERS

Since many beverages are susceptible to contamination or discoloration in contact with iron, filter presses having a cast iron shell and all brass, bronze or copper internal construction are used. A recent development of the United Filters Corporation is a special all-aluminum press, which is an item of value to the chemical industry generally, for the handling of corrosive liquids.

A demonstration was made of the manner in which Filter-Cel assists filtration of turbid liquids, by improving the clarity of filtrate, increasing capacity of equipment, decreasing labor of cleaning press, shortening the process and avoiding dilution in washing.

GLASS-LINED EQUIPMENT

Glass-lined steel tanks and containers are extensively used for storing beverages and beverage syrups. The exhibits of Elyria and Pfaudler products were so arranged as to show the flawless character of the linings.

RECORDING AND CONTROLLING INSTRUMENTS

The possibilities of automatic control of temperature, pressure, etc., in manufacturing processes were illustrated by an excellent line of "Tycos" and "Tag" specialties.

STERILIZERS

Two methods of sterilizing were shown:

(a) By ultra-violet light. James B. Clow & Sons demonstrated a Type H-2, 1000-gal. per hr. ultra-violet-ray sterilizer, together with a small 120-gal. Type B-2. The number of these machines in commercial plants has demonstrated their efficiency for this class of work.

(b) By ozone. The Electric Water Sterilizer & Ozone Co., Scottsdale, Pa., operated a sterilizer unit consisting

of ozone-producing and absorption apparatus mounted en bloc, capacity 550 gal. per hour, and an electric water sterilizer, operating on the electrolytic principle, capacity 1000 gal. per hour.

BOTTLING AND REFRIGERATING PLANTS

Complete low-pressure bottling and refrigerating plants were displayed by the Liquid Carbonic Co. in a booth specially constructed in black and silver. The total effect was pleasing to the eye and the operation most instructive. The management was congratulated on every hand on its success in bringing together so scattered a trade as the beverage industry, thrown into exceptional confusion by the present novel conditions. The officers of the Beverage Exposition are: President and general manager, Felix Mendelsohn; secretary, Henry E. O. Heinemann; treasurer, P. M. Harwood. The headquarters are 1253 S. Michigan Ave., Chicago, Ill.

Chemical Warfare Service

TWO recent developments favoring the continuation of the Chemical Warfare Service as a separate unit have been the adoption of a resolution by the American Electrochemical Society and the appearance of Major General Sibert before the House Committee on Military Affairs.

At the October meeting of the board of directors of the American Electrochemical Society, President Bancroft submitted a report of the committee on resolutions regarding Chemical Warfare Service. The resolution, copies of which were forwarded to the members of Congress and the Army authorities concerned, is as follows:

AMERICAN ELECTROCHEMICAL SOCIETY RESOLUTIONS

"Whereas the development of science and research is of paramount importance not only to the military establishment of the United States, but to the welfare and security of the entire nation; and

"Whereas the bill introduced into Congress for the reorganization of the Army (Senate 2715, 66th Congress) is not only clearly destructive of the Chemical Warfare Service, but is so drawn as to belittle all scientific and technical work in the Army and make it subordinate to the unscientifically trained officer; Therefore, be it

"Resolved, that the American Electrochemical Society urges strongly that any legislation for the reorganization of the Army shall provide for the continuing of the Chemical Warfare Service as a separate staff bureau as at present; shall provide for the commissioning of staff officers in the corps and departments in which they are to serve; and shall in general accord to the technical man full recognition and opportunity throughout every grade and department of the military establishment."

GEN. SIBERT'S TESTIMONY

The appearance of Major General William L. Sibert, the director of the Chemical Warfare Service, before the Committee on Military Affairs of the House of Representatives, brought out little information that had not been presented earlier to the Senate committee, or has been set forth in the various published articles by General Sibert and other officers of the Chemical Warfare Service. In making his plea for an organization separate from the Engineer Corps, or the Ordnance Department, General Sibert pointed out the evils of hav-

ing a unit too large for efficiency. Speaking of the Ordnance Department, he said that "when any branch of the service becomes so extensive in its various elements of work that no one man can keep sufficiently acquainted with the details of those various elements so as to direct them intelligently, it then is time to divide such an organization into smaller independent units." He pointed out that the chemical work of the Ordnance Department is not extensive, since the chemistry of powders is not a very big subject. The Ordnance, he said, is essentially a mechanical engineering department.

The chairman of the committee called General Sibert's attention to the statement by the Chief of Staff that it would be difficult to carry on experiments with gas around populous centers. General Sibert replied by citing the fact that experiments have been in progress for two or three years with all kinds of noxious and toxic gases at American University, which is practically in the City of Washington.

General Sibert testified that at present gas experiments are being conducted only in a very small way. This is due to the fact that equipment is now being moved from American University to the Edgewood Arsenal. In addition, the General Staff has not had an opportunity as yet to pass upon the program which General Sibert has proposed for field work. He stated, however, that the service is beginning to provide gas officers for the various infantry divisions. He took advantage of several opportunities to make clear to the committee the value to a nation of large chemical industries.

Imports Into Canada During the Past Two Years

Trade statistics as issued by the Canadian Government show that the imports into the country from the United States decreased from \$752,810,282 for the 12 months ended July, 1918, to \$695,268,163 for the year ended July, 1919. During the same time exports to the United States increased from \$411,860,008 to \$431,705,058.

Exports to Great Britain fell from \$744,380,550 for the year ended July, 1918, to \$546,866,571 for 1919; exports to France fell off from \$150,597,165 to \$80,945,701 during the same period.

The value of some of the principal articles imported into Canada for consumption during the past two years is shown in the following table:

	Twelve Months 1918	Ended July 1919
Articles for army and navy	\$77,753,452	\$27,573,360
Asphaltum and asphalt	361,950	385,380
Books and printed matter	6,645,730	8,704,152
Breadstuffs, . . .	20,436,386	21,486,310
Bricks, clay, and tiles	4,645,532	3,072,649
Chemicals	29,845,615	25,468,964
Coal:		
Anthracite, . . .	27,469,699	28,189,872
Bituminous	46,896,893	37,413,847
Cotton	64,795,347	65,192,086
Earthen and china ware	2,321,030	2,480,181
Flax, hemp, and jute	12,171,111	13,477,214
Furs	4,506,416	5,105,633
Hides and skins	7,069,142	7,936,129
Leather	10,493,774	11,161,087
Meats	13,263,400	16,468,031
Metals:		
Brass	5,074,550	4,657,651
Copper	6,290,411	6,028,100
Gold and silver	297,250	306,147
Iron and steel	156,322,603	151,172,247
Lead	1,288,813	626,366
Tin	14,570,566	11,975,234
Zinc	1,643,725	880,025
Paints, color, and varnish	3,341,986	3,262,580
Paper	7,542,037	8,813,615
Rubber	12,794,619	11,343,353
S soap	1,248,613	1,001,099
Stones, marble, and slate	1,987,642	2,265,614
Sugar and molasses	36,465,940	47,946,288

Cellulose Symposium

THERE was an interesting symposium on cellulose at the regular meeting of the New York Section of the American Chemical Society held at Rumford Hall in the Chemists' Club on Nov. 14. The first paper was by Mr. Wallace P. Cohoe, and had to do with "Present Day Problems in Regard to Cellulose."

There is a tradition, he said, that quick-growing plants do not make good paper, but this he declared to be erroneous. Bamboo and flax straw are excellent materials, and hemp and jute wastes are important for the purpose. Bagasse has not been profitable, so far, but in this respect it is possible that the final word has not been said. The uses of paper and pulp are constantly increasing, and new sources must be found. Among new uses he cited the nitration of wood pulp and artificial silk as important consumers. Rugs are made of mixtures of paper yarns with cotton and wool. The yarns made of paper fiber have slight holding power when wet and they must be heavily sized, which tends to make them heavy and stiff. Sisal and jute may be used for making paper, and good results are obtained from freshly handled manila waste. In Germany a great deal of paper cloth has been used for bed ticking. Paper burlaps are coming into use. The future of paper textiles, however, is not promising for human wearing materials. The art of the hydration of paper-making fiber has not yet been discovered.

Cellulose is at once perishable and permanent. Millions of tons are produced every year and turned back into the soil, and yet cloths from the tombs of the Ptolemys are still good and strong. We are still at sea in regard to the chemistry of cellulose.

Professor R. H. McKee of Columbia remarked in regard to paper materials that we had not yet adequately addressed ourselves to their proper culture. We use very little wild rice and no wild wheat, because the yield is so slight, nevertheless in reforestation we plant wild rather than hybrid trees.

Wild bamboo grows a foot a day, but our forest woods are usually of slow growth. New hybrids of trees have been developed that grow very fast. He spoke of a poplar hybrid that grew 27 ft. in 27 months, and a walnut hybrid that achieved remarkable growth, and yet the wood of these was no softer than that of the original stocks. He urged a greater encouragement of the study. If chemists lead in encouraging foresters to develop fast-growing trees to meet present and future needs, the woods are likely to be forthcoming.

Dr. Harold Hibbert made an earnest plea for a close study of the cellulose molecule, and he noted that more particularly the American chemical journals had been less diligent in this respect than their British and German contemporaries. The difference between monomolecular cellulose and sugar is one molecule of water, so that cellulose may be described as dehydrated sugar. Now, although the hydration of cellulose is not an accomplished fact, it certainly would be worth while to develop the art, and he believed that in view of the immense importance and scope of the cellulose industry, a Government institute should be founded to work on cellulose. He proposed an interesting hypothesis in regard to the structure of the cellulose molecule which may appear later in an original paper.

Dr. J. E. Miner presented a paper on her studies on cellulose hydration problems, and Messrs. Hamilton and Bradshaw gave their experience in the du Pont establishments with the nitration of wood pulp.

The Chicago Electrical Show

THE Electrical Show held in the Coliseum at Chicago Oct. 11-25, while in the main an exhibit of interest to the general public in its displays of household appliances and lighting fixtures, contained a few items of value to the chemical industries.

The Booth Electric Furnace Co. had a corner displaying some products of the furnace and photographs of the new designs. The Detroit Electric Furnace Co. showed a 500-lb. rocking furnace. Both the Edison Storage Battery Co. and the Electric Storage Battery Co. exhibited various sizes of storage batteries and accessories. The Elwell-Parker Electric Co., displayed two of the small industrial vehicles for use in warehouses and for indoor transportation throughout the factory. The Thomson Electric Co. advertised electric metal working machinery.

One display of particular note in ceramic work was contained in a glass case at the booth of the National

SMALL VERTICAL VACUUM FURNACE

Lamp Works. The ingredients for manufacturing the milk-white glass used in forming the new "White Mazda" incandescent lamp bulbs were contained in small crucibles adjacent to the finished product. They were labeled Litharge, Soda Ash, Feldspar, Fluorspar, Silica Sand and Niter. Relative quantities were not given.

A small laboratory type of electric vacuum furnace was exhibited by the General Electric Co. This is shown in the figure and contains a heating element of graphite wound as a helix within a steel vacuum chamber with lead gasketed joints.

A crucible of carbon, graphite, alumina, tungsten or other refractory required for the material to be treated is placed in a chamber within the helix. The temperature may be brought to any desired point up to 3100 deg. C. and the performance noted through a mica window in the top of the furnace. At 3100 deg. C. the power consumption is 15 kw. Maximum size of crucible which can be inserted is 1.5 in. in diameter and 4 in. high. This furnace may be adapted in the preparation of metals, alloys, carbides and silicides; in determining melting points of refractories, metals, etc.; in calibration of optical pyrometers; in distillation of refractory substances, and in study of equilibrium in reactions depending upon the pressure of the gaseous phase. Excellent quantitative results are said to be obtained with this device.

The Commonwealth Edison Co. displayed an electrical design over the door which outlined in lights the increase in cost curves of food, clothing and rents as compared with the decreasing cost of electric power.

Chemical Warfare Service Wants Recruits

Men with chemical and engineering experience are being called upon by the Secretary of War to enlist with the Chemical Warfare Service. It is the desire to obtain 1000 recruits at the earliest possible date. Enlistments are for 1 or 3 years. The men will be enlisted in the infantry, but assigned to the Chemical Warfare Service.

With the Chemical Warfare Service calling for recruits on the one hand, and asking assistance in placing some of its men in civilian positions on the other, it would seem that a conflict exists. As a matter of fact, however, there is no conflict, as the men being recruited are to serve as privates, while the men for whom positions are being sought are officers who desire to be relieved from service. Approximately 40 per cent of the officers remaining in the Chemical Warfare Service want to return to civilian employment as soon as a position that is sufficiently attractive opens. As practically all of the enlisted men in the Chemical Warfare Service had come in for an emergency only, they have been mustered out, and it is now necessary to build up a new enlisted personnel.

The Army Reorganization bill is taking form, with the probabilities pointing to the recognition of the Chemical Warfare Service as a distinct branch of the Army.

New York Section Meeting, American Chemical Society

At the December meeting of the New York Section, held on the evening of Friday, Dec. 5, in Rumford Hall, the following officers were elected for 1920: Chairman, Ralph H. McKee; vice-chairman, John E. Teeple; secretary-treasurer, Herbert G. Sidebottom; executive committee, D. W. Jayne, C. H. Herty, F. J. Metzger and K. G. Mackenzie. In addition, twenty councilors were chosen to represent the Section.

The technical program for the evening was opened by Dr. K. George Falk of the Harriman Research Laboratory, Roosevelt Hospital, who spoke on "New Methods of Food Dehydration." This method of dehydration, which consists in heating the food product at a relatively low temperature in a vacuum, was developed primarily for the purpose of preventing spoilage of meat during transportation in war time. Details of the process have been published in the *Journal of Industrial and Engineering Chemistry*.¹

This paper precipitated a lively discussion in which Prof. S. C. Prescott of the Department of Agriculture took an active part. He has done a great deal of work on the air-blast dehydration process² and argued strongly in favor of this method.

The latest advance in this method is drying by means of moist warm air, which sounds paradoxical but is in reality most logical. The drying operation is started with warm air containing a carefully regulated amount of moisture so that only a portion of the moisture in the food product can be taken up by the warm air. As the drying proceeds, the percentage of moisture in the incoming warm air is diminished progressively, until

at the end dry air is used. The process is in effect an application of the counter-current principle. It is claimed that by this method the original flavor and palatability of the food are retained.

The program was concluded by a very interesting paper on "Emulsions," presented by Dr. A. W. Thomas.

Fixed-Nitrogen Corporation Proposed

Manufacture, production, and development of atmospheric nitrogen for military, agricultural, and other purposes is provided in a bill introduced simultaneously in the Senate and the House of Representatives. The bill was drafted in the War Department. It provides for the creation of the United States Fixed-Nitrogen Corporation. The stock in the corporation is to be owned exclusively by the Government. The bill empowers the Secretary of War to designate any five persons to act as an organization committee with authority to organize the corporation.

Among other things the corporation is to have the power to make contracts, appoint a board of directors, other officers and employees and to fix their salaries. The corporation may sue and be sued. It is to be conducted under the supervision of a board of directors consisting of not less than three nor more than 11 members, to be appointed by the Secretary of War. They are to hold office at the pleasure of the Secretary of War. The board of directors is to perform the duty usually appertaining to the board of directors of private corporations.

The corporation is to have the power to purchase, operate, and develop the nitrate fixation plants numbered 1 and 2, located respectively at Sheffield and Muscle Shoals, Alabama, together with the machinery, real estate, and laboratories pertaining thereto. This is to include the research laboratory at Washington, the Waco Limestone Quarry in Alabama, and the Electric Power Unit at the Warrior River Station of the Alabama Power Co.

After its completion the hydro-electric power plant now being constructed at Muscle Shoals is to be operated by the corporation. The corporation is also authorized to purchase, lease, or otherwise acquire United States or foreign patents and processes. It also may sell and export any of its surplus products not purchased by the United States or by persons within the United States.

The Question of Fuel Oil in France

A commission presided over by M. Henry Bérenger, Commissaire Général aux Essences et Combustibles, has been set up by the French Minister for Public Works to study the question of oil fuel in France. The following three decisions have already been arrived at: (1) The substitution of heavy-oil fuel for coal everywhere in the heavy industries and all public services is of the greatest possible urgency. (2) A progressive program is to be worked out for the adaptation of boilers and plants to burn oil fuel as from Nov. 15. (3) An organization is to be set up for at least five years for the national supply of heavy-oil fuels in co-ordination with the scheme for importing and producing coal. M. Bérenger and General Gassouin are to be in charge of the scheme in co-operation with the City of Paris and the Minister of Reconstruction.—*Iron and Coal Trades Review*, Nov. 21, 1919.

Chemistry and the South*

An Exposition of the Interrelation Between Fuel, Power, Cellulose and Mineral Wealth, With an Indication of the Future Advance in Southern Industry When Founded on Its Obvious Advantages

BY ARTHUR D. LITTLE

THE American Institute of Chemical Engineers is composed of men who are above all intensely practical, men who make it their life work to apply chemistry to useful ends. We have come to Savannah not merely to enjoy a proverbial and graciously extended hospitality, but chiefly because we recognize that here there is much for us to learn. Your cotton oil mills, your great fertilizer factories, the secrets of your naval stores industry, the doors of many plants distinctively Southern in their type have been generously opened to us. We shall take with us on our return new and enduring impressions of Southern courtesy and kindness, convincing evidence of the magnitude of industrial achievement in the South, and a new appreciation of the wealth of resource and of opportunity in this supremely favored section of our country, but our mission will have failed unless we leave behind us a message so vital and direct in its importance that it secures and holds your attention and thereafter influences your action. And that message in a word is this: "The future of the South is in chemistry."

To insure acceptance any such general thesis properly requires demonstration. Suppose we begin by considering for a moment what the South already owes to chemistry.

The manufacture of fertilizers and the effective use of these artificial manures in the growing of crops are obviously based on chemistry and controlled by the laboratory findings of works chemists, the experiment stations, and the Bureau of Chemistry. The farmer, wiser than most purchasing agents, buys an analysis. Agricultural chemistry, with all that it means to the South, began in the laboratory of Liebig and gained recognition in this country chiefly through the writings and work of Johnson. The essential elements with which growing crops must be supplied are potash, ammonia, and phosphoric acid. It was the refined and classic work of the Dutch chemist Van't Hoff in physical chemistry which rendered possible the separation of the potash from the salts of the Stassfurt mines; the world has long derived its ammonia from the chemical processes of the gas works and by-product coke ovens; today it turns to the atmosphere for the larger supplies of ammonia and nitric acid which its growing needs demand and secures them by the chemical and electro-

chemical methods of nitrogen fixation, which, incidentally, have placed new values on Southern water powers. The nitrogenous fertilizer cyanamide is a direct descendant of calcium carbide, first produced commercially by Willson at Spray, North Carolina. The essential constituent of phosphate rock is rendered available by treatment of the rock with that basic chemical product sulphuric acid, while chemical processes have brought into use and service the low-grade ores contaminated with fluorine and alumina.

At the recent World's Cotton Conference in New Orleans it was stated that in growing cotton there was used on a one-horse twenty-seven acre farm selected as a type six and three-fourths tons of fertilizer worth \$391.50 and one ton of nitrate of soda worth \$90. The figures gain significance when we consider that the pre-war acreage, now somewhat reduced, was 37,000,000 acres.

Upon this vast expanse the South has annually raised for years an average of about 13,000,000 bales of cotton. The 1919 crop is estimated at 11,000,000 bales of staple worth about \$150 a bale, with 5,000,000 tons of seed valued at \$70 a ton—a total increment to Southern wealth of at least \$2,000,000,000.

In no small proportion these values are due to chemistry. If they are attributed to the war we have only to reply that without chemistry the war could not have been fought at all, while in the absence of guncotton, which is merely cotton plus chemistry, it could only have been fought at great disadvantage to our allies and ourselves.

But we are happily now concerned with the peacetime uses of cotton. How far has chemistry extended them and put new values on the cotton crop? Cotton bleaching, which permits its use in fabrics of the finer sorts, is based primarily upon the discoveries of Schule,

Weldon, LeBlanc, and Solvay, chemists all of them, and with the exception of the discoverer of chlorine, chemical engineers. Dyeing and printing, which so greatly promote the sale of cotton fabrics, involve pretty much the whole range of chemistry and are tied into its most modern developments, physical and colloid chemistry. The mercerizing process as ultimately developed by Thomas and Prevost imparts to cotton a wonderful silky luster and resulted in an enormous extension of its use in fabrics of the higher grades.

You will again be surprised to know that at least 2,000,000 spindles are to-day engaged in the business of converting cotton into automobile fabrics. There are 150,000 tires consumed daily. Within one or two years the tire production will have increased by 50 per cent, and spindles to the number of 1,000,000 more in this one industry will call to the South for new supplies of cotton.

CELLULOSE

Cotton in its purified form is the type of that wonderful substance cellulose, the structural basis of all plants and thereby the greatest structural material in all the world. The South has an interest in the chemistry of cellulose, for of it her forests are built and on it her entire agriculture depends. The discovery of nitrocellulose by Schönbein in 1845 has resulted in an extraordinary concatenation of industrial, economic, and political consequences. From it came smokeless powder, the guncotton in the war heads of German torpedoes, the collodion of the surgeon, artificial silk, celluloid in countless shapes, substitutes for leather, the moving-picture films, the finish on brass beds, and the eyelets on our shoes. The South must credit Schönbein with the values placed on cotton linters and the shorter fibers adhering to the hull.

A more recent but analogous compound, cellulose

acetate, made by treating cotton with acetic anhydride and sulphuric acid, has already attained an importance only secondary to the nitrate in the arts of peace and war. In the form of cellulose acetate Southern cotton functioned high above the battlefields of Europe as the protective covering of airplane wings. To the same compound we are indebted for non-inflammable moving-picture films, for artificial silk of an altogether new order of merit, artificial bristles and horsehair, and for a substitute for celluloid wholly free from the dangers which always attend the manufacture and which sometimes accompany the use of this ubiquitous material.

But chemistry does not stop with the cotton fiber; it has enriched the South still further in the values it has put upon the cottonseed which once clogged Southern streams. Cottonseed today is worth \$70 a ton because chemists have derived from this nuisance of pre-bellum days—it is hard to recall the Civil War, to which I now refer—edible oil, a solid substitute for lard, soap stock, a concentrated cattle feed, and residues of high fertilizing value.

SOUTHERN BAUXITE AND SULPHUR

Southern bauxite, without chemistry, is merely a stone to throw at a dog. With chemistry, it controls the aluminum industry of the world. Louisiana sulphur lay secure beneath 500 ft. of quicksand until the chemical engineer Frasch brought it to the surface by methods so simple and so cheap that the groaning Carusi of Sicily were released from their intolerable burdens and set to work in sunshine on the soil whereunder they had toiled.

But why has sulphur any value in Sicily or Texas or Louisiana? Solely because the co-ordinated studies of generations of chemists have made it the foundation stone of modern chemical industry. As such it functions in sulphuric acid in countless reactions through the whole range of manufacture.

The largest sulphuric acid plant in the world is at Ducktown, Tennessee, but here the acid is made from smelter smoke and constitutes a striking example of a nuisance transformed by chemistry into a profit. Eight hundred tons of Southern sulphur are used each day in America alone, to an annual value of \$7,000,000, because fifty years ago Tilghman, in Philadelphia, applied chemistry to the production of wood fiber for use in paper making.

Because Braconnot, in 1819, converted cellulose to fermentable sugars great plants are now operating in Louisiana and South Carolina converting the wood wastes from yellow pine lumber mills into ethyl alcohol. A Southern chemist, Charles H. Herty, held in honor and affection by chemists everywhere, has revolutionized your naval stores industry. Moreover, an actual \$500,000 and a potential \$1,000,000 at least has been added to the annual value of the turpentine crops by a simple change in chipping method based on studies made in France on the pathology of the wounded tree.

OTHER NATURAL SOUTHERN PRODUCTS

Statistics often prove without convincing. They may compel the reason to assent without firing the imagination or arousing the will to action. I believe, however, that no one with the capacity to understand their true significance can review the colossal figures which set forth the natural resources of the South without first being stunned and overwhelmed and soon thereafter filled with the vision of their stupendous possibilities.

The South contains in superabundant measure the basic raw materials required for the development of great groups of co-ordinated industries founded upon chemistry and on a scale incomparably more vast than anything yet known. She has more than half the iron ore in the United States and 75 per cent of all the coking coal; great stores of lignite, natural gas, and oil. Here is the purest salt which occurs in nature, the cheapest and purest sulphur, clays endless in variety and extent, bauxite for aluminum and for abrasives, limestone adjacent to coal and iron, phosphate rock, gypsum, barytes, shale and quartz, ores of zinc and manganese, lead and nickel, titanium and tin. There is enough wood waste to supply the country's need for paper, and the world must soon look to the stumps on millions of acres of cut-over lands for its rosin and its turpentine. The cotton fiber is itself the raw material for many chemical industries of magnitude, and the short hull fiber, to utilize which in smokeless powder huge Southern plants were built, is now available for paper making and other arts of peace. The products and the potentialities of the cottonseed now have a rival in the humble peanut, and in at least one Southern locality the peanut crop exceeds the cotton crop in value. In the South as a whole the value of the corn crop already approximately equals that of cotton and affords a basis for great corn product industries. To such material resources, with many others, to which no reference can here be made, the South adds the potentialities of 5,000,000 hp. in the available energy of her streams.

SOME GREAT SOUTHERN PLANTS

The South is no stranger to chemical developments on a great scale. The largest electrolytic copper plant in the world refines 720,000,000 lb. a year at Canton, Maryland; Ducktown, Tennessee, produces 1000 tons of sulphuric acid a day. The war called forth in Sheffield, Alabama, nitrate plants designed for a carbide production equal to that of the entire continent and for 100,000 tons of ammonium nitrate yearly. The Old Hickory plant at Nashville had an estimated cost of \$90,000,000 and in nine powder lines, each of a capacity of 100,000 lb. a day, took the raw crude cotton and, producing both the acids and the solvents used, turned out the finished powder. The plant at Nitro, West Virginia, was designed for 625,000 lb. a day of powder. To the South must also be credited the great plant of the du Ponts at Hopewell.

These industrial achievements, stupendous though they are, derive their chief significance as evidence and measures of what will be accomplished in the South when capital joins hands with chemistry in the co-ordinated development of Southern resources.

J. W. Richards wisely and truly says, "The industries are fundamentally based on the imagination." Those who would share in this great development must mix imagination with statistics and have the courage to accept their findings and the initiative to act on them. What then may chemistry be reasonably expected to accomplish in the South? And how?

SOUTHERN FERTILIZER INDUSTRY

With increasing density of population in the South and throughout the country a more intensive agriculture must everywhere be practiced. A great expansion of the Southern fertilizer industry, already so important, would seem to be assured. Improved methods of production will check the abnormal wastes which now accom-

pany the mining of phosphate rock, raise the intrinsic value of the product and permit of larger profits. The potash content of the gray iron ores of Alabama will be rendered available and supplied to agriculture as a by-product of the blast-furnace. From the expanding portland cement industry more by-product potash will be similarly derived. Ammonia from by-product coke ovens will be recovered in vastly greater quantities. Some extension of cyanamide production may be expected, but the vast stores of cheap nitrates and ammonia which the new agriculture will demand will come from the atmosphere by direct nitrogen fixation.

SOUTHERN WATER POWER INDUSTRY

Southern water powers will play an important although not necessarily a controlling part in their development. In the best interests of the South, it is in any case desirable that they be not linked up too exclusively to electrochemical processes, since these create relatively little opportunity for labor. It is incomparably more advantageous to constitute the water powers the centers of diversified and highly developed manufactures, the economic value of which may be a hundred times that of the water powers themselves.

It is probable, nevertheless, that for a generation or two at least Southern water powers are to find their chief applications in the field of electrochemistry, which is already extensive enough to insure a considerable diversity of industry. More and more will the electric furnace become a factor in the steel industry in the smelting of steel itself and in the production of ferro-alloys, of non-ferrous alloys, abrasives, carbide and other products now unknown. Methods of electrolysis will utilize much hydro-electric energy in making chlorine and alkali, chlorates, peroxides, perborates and persulphates.

The extraction of aluminum from bauxite is at last well established as a Southern industry at Maryville, Tennessee. In Alabama are great beds of bauxite only seventy miles from water power and with rich seams of coal between. But the production of aluminum is destined to be far more closely identified with the South. Ultimately will come effective and economical methods for the direct extraction of the metal from clay. Then each of the immense deposits of kaolin in Virginia, the Carolinas, Georgia, Florida and Alabama will be re-constituted as mines of aluminum ore.

SOUTHERN CLAYS AND FUELS

The variety and range of character exhibited by Southern clays is amply sufficient to meet every requirement of the ceramic industries from bricks, tiles and terra cotta through pottery to porcelain. In many instances, the finer sorts have had their usefulness restricted by the presence of titanium minerals in small proportions. Here again chemistry has played its part by demonstrating a simple and inexpensive method for the removal of these impurities, with the result that the purified clays are suitable for the finest chinaware and porcelain. In the pegmatic dikes of the Appalachian region are great deposits of very pure quartz awaiting the enterprise of the glass maker.

Our present methods of utilizing coal are wasteful in the extreme. To set free its energy values we commonly employ means which wholly ignore its far greater chemical values. Moreover, bituminous coal, which constitutes the bulk of our supply, is not a desirable fuel for

use in cities and our supply of anthracite is down to 190 tons per capita. Our railroads are breaking down under the strain already put upon them as transportation agencies and about one-third of their tonnage is coal. All this points to a radical readjustment of our use of coal and to a readjustment which should enormously benefit the South. It means that coal must be burned much nearer to the mine in super-power plants and its energy delivered to great common carrier transmission lines for power linked to hydro-electric developments and operated in co-ordination with them. It also means huge gas works in which the chemical values of the coal are saved as ammonia and tar, the coke converted into artificial anthracite and the gas made available for distribution for light, and heat and power over wide areas. There will follow as a consequence a corresponding development of the higher industries based upon the chemical values thus conserved, and producing dyes, intermediates, synthetic drugs and new types of coal-tar products. Lignite and peat will ultimately be involved in these comprehensive plans and yield their enormous quota of gas, ammonia and briquets.

NATURAL GAS AND OIL

Natural gas, of which the South now yields 80 per cent of the country's whole supply, has not only been wasted shamelessly but was long regarded merely as a cheap and convenient fuel. We are now coming to realize that it has values and potentialities far beyond those of the thermal units it contains. Hundreds of plants now extract gasoline at the casing head, and the gas itself is recognized as a raw material available for many organic syntheses, as for example chloroform. Certain wells, notably those of Petrolia, Texas, have assumed an altogether new importance as sources of helium, urgently required for airships because of its high lifting power, non-inflammability, and low rate of dispersion through balloon fabrics.

Friction will bring the industries of the world to a standstill unless they are provided with a continuous and assured supply of lubricants, and these are practically all derived from petroleum. The impending exhaustion of the petroleum fields of the South is thus a matter of deep concern wherever wheels turn or machinery functions. The rapidly increasing and already extensive use of fuel oil is therefore an economic blunder which one day may be characterized as worse than a crime. Such oil as remains should be conserved until with incomparably greater benefit to the South due provision is made for utilizing its higher values in the production of lubricants, dyes and intermediates and the synthesis of gasoline by methods which Rittman, Cherry and other chemists have already indicated. It is important to remember that the asphaltic oils of the South are more reactive and therefore much more generally available for the higher syntheses than the oils of Pennsylvania, which have a paraffine base.

SOUTHERN METALLURGY

The wet methods of metallurgy as exemplified in the cyanide and chlorination processes have upset the economic balance of the world through the inordinate increase in gold production due to them. It may be regarded as certain that other wet methods will be developed, and it may easily be soon, which will render possible the profitable working of the great beds of low-grade ores of various metals existing in the South, as

for instance, the nickel ores of Georgia or the low-grade zinc ores of Missouri.

IRON AND STEEL INDUSTRY IN THE SOUTH

It needs no prophet to point out the inevitable vast extension in the South of the iron and steel industry already firmly established on a great scale. Around it will naturally evolve groups of associated and dependent manufactures—potash and slag cement; chemically pure iron and special alloys; plants for working up the by-products of the coke oven; new foundries and plate and wire mills and all the multitudinous activities based on steel and controlled by chemistry.

The basic chemical products, sulphuric acid, soda, bleaching powder and others known collectively as heavy chemicals, require for their manufacture sulphur, salt and limestone. Nowhere are these essentials available more profusely than in Louisiana, and the potentialities of their concurrence are magnified by their proximity to the great Caddo gas field, the oil of Texas and Louisiana and the cheap coal of Alabama.

ROSIN AND TURPENTINE

The world now depends chiefly upon the South for its supply of rosin and of turpentine, both relatively crude products and for the most part crudely used. Yet rosin is the cheapest organic acid available to chemistry and should be made to yield products of higher value and wider range of use. Turpentine is also the cheapest volatile oil and clearly indicated as the logical starting point for many syntheses. It is already the raw material for synthetic camphor, and camphor is worth \$3 a pound.

The end of the virgin supply of crude turpentine is already in sight and much nearer than is generally realized. Fortunately for the South and for the world, chemistry has performed the double service of demonstrating that cut-over lands may profitably be cleared and new supplies of rosin, turpentine and pine oil extracted from the encumbering stumps of long-past lumbering. Even from the spent chips of the extraction plant, excellent Kraft paper has been made.

BRIGHT PROSPECTS FOR THE SOUTH

In the future, the South must look for much of its prosperity to the utilization of present wastes. They are colossal in the lumber industry, in gas and oil and agriculture. A ton of straw, for example, will yield 11,000 ft. of gas or 800 lb. of high-grade paper. Great stores of ethyl alcohol, rosin, turpentine, gas and tar and many thousand tons of paper, container and building boards, fruit wrappers, bags and twine are potentially present in the wood waste burned in the South each day.

The high price of pulp wood has arrested the development of paper making in the North and for the next decade at least the expansion of the industry will be in the South, which offers the cheapest pulp wood on the continent outside of Alaska, and which offers also, in close association thereto, the raw materials required for its production.

To insure these benefits the South needs, as recently pointed out by Coates, the creation of an atmosphere in which the spirit of manufacturing enterprise may develop freely. It still lacks an adequate number of industrial leaders. It needs far more chemists and should place far more trust in those it has. It needs research and more research.

Plans for Manufactures Census Completed

SPECIAL effort is being put forth to make the manufacturers section of the approaching Fourteenth Decennial Census the most complete and comprehensive inventory of the nation's manufacturing establishments ever taken, according to officials of the United States Bureau of the Census who have this work in charge.

The schedules which will be used in tabulating the information about the country's industrial resources have already been prepared and printed. These schedules will be mailed to every manufacturing establishment in the United States during December, so that factory owners and managers shall be in a position to familiarize themselves in advance with the questions which are to be answered when the records of the past year's business have been compiled. The questions relate to the calendar year 1919.

LAST CENSUS IN 1914

In 1914, the year the last manufactures census was taken, about 275,000 manufacturing establishments were listed by the Census Bureau. This time more than 300,000 establishments will be sent schedules. In addition to this it is expected that about 50,000 mines and quarries will also be reported.

The inquiries relating to manufactures, as specified by the act of Congress providing for the census, include the name and location of each manufacturing establishment; character of organization, whether individual, corporate or other form; character of business or kind of goods manufactured; amount of capital actually invested; number of proprietors, firm members, copartners and officers, together with the amount of their salaries; number of employees and amount of their wages; quantity and cost of materials used in each establishment; quantity and value of products; principal miscellaneous expenses; time in operation during the year; character and quality of power used; and character and number of machines employed.

The questions as outlined above will be covered by the general schedule which every establishment will receive. In addition to this a supplemental schedule will be sent to the 68 principal industries as classified by the Census Bureau. This supplement schedule, it is expected, will allow detailed statistics of output to be collected and set forth under the heading "products manufactured."

The census of manufactures is limited to manufacturing establishments with an annual product of at least \$500 conducted under what is known as the factory system, exclusive of the so-called neighborhood, household and hand industries. However, no establishment is too small to be counted by the Government if it comes within the definition of a manufacturing establishment.

INFORMATION TO BE CONFIDENTIAL

Census Bureau officials emphasize the fact that all information gathered by the census is strictly confidential, made so by act of Congress, and is for general statistical purposes only. The same is true of the censuses of population, agriculture, mines and quarries, oil and gas wells and forestry and forest products.

Many startling figures are expected to be shown by the approaching compilation, inasmuch as the industries of the country were for the most part in a subnormal condition in 1914, the year the last manufactures census was taken.

Pure Gum Shellac

Origin of Sticklac—Entomology of the *Tachardia Lacca*—Crops—Manufacture of Native and Machine Grades—Makers' Marks and Chemical Analyses—Specifications for Pure Shellac Varnishes
Based on Experience With Impurities Encountered in Manufacturing Processes

BY CHESTER H. JONES

THE continued and increasing use of shellac in the arts and industries and recent requirements for a pure neutral varnish to resist the action of various chemicals and electric pressures have awakened an interest in the circumstances surrounding the origin and method of production of the gum, with especial reference to the possible impurities which may enter into the processes employed in obtaining the commercial grades. Investigation has shown that a surprisingly large percentage of the better informed persons, and even chemists, who are familiar with this everyday substance as an ordinary varnish, have little or no knowledge of its origin and no information for use in distinguishing its value as compared with other varnishes. There is also little information available on the percentages, kinds and effects of impurities entering into the analysis of the different types or marks.

Many thousands of years ago in the mystic and interesting land of India it is recorded in the Sanskrit literature that the aboriginal tribes, seeking a coloring matter for their ornaments and clothing, found a resinous incrustation on the twigs of the *Lakhsataru*, or lac-tree, and by simple extraction in water secured a red dye known as lac-dye. This had been a standard article of commerce and chief competitor of cochineal up to the advent of synthetic dyes, but is now entirely discarded in the washing processes. The decrease in the use of the dye began in 1868 and was stopped entirely about 1900.

The value of the lac-resin as a varnish was discovered many centuries later, when probably its first use was the melting up and casting into beads, amulets and other native ornaments. The earliest record as an applied coating to woodwork was noted by Akbar in the *Ain-i-Akbari* in 1590. In 1596 a Dutch explorer describes its use in a European publication, but evidently was without knowledge of its origin.

ORIGIN OF STICKLAC

The lac resin from which shellac is derived is made by an insect known as the *Tachardia lacca*, and its product, found as an incrustation on the smaller twigs of several types of tree, is broken off with the supporting twig, giving the sticklac of commerce. The specimen shown on the right-hand side of Fig. 1 is a branch of the dhak tree well covered with a fully developed incrustation.

The insects swarm twice each year, much as the bee, with about 5 per cent of the swarm consisting of males. Being gregariously inclined, they alight in densely packed masses on the twigs of the tree, as shown on the left hand figure in Fig. 1. An enlarged view of the top of the same twig is shown in Fig. 2.

As soon as the larva alights it buries its beak through the bark into the tender part of the tree, and inserting

a sucking tube, proceeds to withdraw the sap. After absorption of some of the constituents of the sap and modification of others within the body, it excretes a fluid at the anal end. This excretion forms a covering over the insect and, slowly hardening on contact with the air, a cell is produced. As these cells are very close together, the whole coalesces and takes the form of a crust.

ENTOMOLOGY OF THE *TACHARDIA LACCA*

This insect being a most noteworthy little chemical factory in itself, and with habits and troubles which affect greatly the market quotations for its product, brief reference to the entomology should be of value.

The bug belongs to the order known as plant lice, or scale insects, whose habits are to suck the sap of plants with the proboscis, and to that particular group in the family which covers the body with an excretion. The original purpose of this performance was to protect from predacious enemies while attached to the plant.

The newly hatched insect is red or orange colored and very small. Fig. 3, right hand figure, shows first instar, active stage, magnified 40 times. Actual length of body is about $\frac{1}{16}$ in. At the end of the first month the female has built a cell around herself as shown in left-hand side of Fig. 3, and is about $\frac{1}{18}$ in. in length.

FIG. 1. SWARMING INSECTS AND STICKLAC

The body has turned dark red and the appendages have nearly disappeared.

When about two and one-half months old the female is impregnated by the male and continues to grow and exude lac for another two and one-half months. The ovary becomes so enlarged as to occupy nearly the whole body and is filled with a bright red fluid. This is the basis of the lac-dye. From this fluid the eggs form during the sixth month. The female has ceased feeding.

The lower right hand figure in Fig. 4 shows the female cell thirteen weeks after inoculation and the upper left hand figure shows the dead female cell with young emerging. This last, then, is a single cell nearly ready to harvest for sticklac.

The male insect after a short period of activity also comes to rest on a twig and forms a cell. There are two varieties of males as shown in Fig. 4. At the end of the sixth month the swarming shown in Figs. 1 and 2 occurs, and the crop is ready for the gathering.

CROPS OF STICKLAC

India is the source of all shellac for the world markets, and the bulk of the sticklac is harvested there. Some of the latter, however, comes from the Malay Peninsula and Siam to Calcutta factories.

There are four crops gathered each year. The "By-sackie" crop is gathered in April in the Sind, Punjab, Bundelkand Bengal and Birbhum, reaching the factories in May and June. This is the principal crop of the year supplying the T N (truly native) grade.

FIG. 2. SWARM OF TACHARDIA LACCA

FIG. 3. RIGHT—FIRST INSTAR MAGNIFIED 40 TIMES.
LEFT—FEMALE ONE MONTH AFTER INOCULATION,
25 TIMES ENLARGED

The "Jetowa" is gathered in August and September in Birbhum and Upper Burma. It is of fine quality and is used largely in seeding. The "Rungeen" crop is harvested in October and November in Sind, Punjab, Bundelkand Palamau, Birbhum, Assam and Upper Burma. There are said to be three crops per year in Burma.

The "Koosmi" crop, gathered in November and December, furnishes the finer grades. The quantities produced at each harvest in terms of finished shellac are approximately as follows:

	Lb.
By-sackie crop	53,000,000
Jetowa crop	1,300,000
Rungeen crop	3,600,000
Koosmi crop	11,500,000

FORESTRY

Each province or locality produces its own particular quality and kind of sticklac, which is determined very largely by the variety of tree on which the insect feeds. There are 88 varieties of lac-yielding trees, the most important of which are:

Butea frondosa (palas or dhak)
Cajanus indicus
Ficus bengalensis
Ficus religiosa
Ficus rumphii
Schleichera trijuga
Zizyphus jujuba

The preservation and cultivation of these trees to prevent entire destruction from the drain which they undergo during feeding of the lac insect and destruction of other agencies are carried on by the Indian Government. The Conservator of Forests, in charge of this work, also is responsible for keeping down the insects which prey upon the *Tachardia lacca*, and the promotion of the lac industry in general.

MANUFACTURE AND REFINING

The raw material, consisting of sticklac and grainlac, is sold on the ground to middlemen who take it to the factories. Grainlac consists of incrustations broken from the twigs by wooden mallets, leaving the twigs on the trees. Fig. 6 shows the crop being harvested, dried and collected.

There are two methods of manufacture, namely, hand, or native, and machine method. The native process of

refining is much the same as has been employed in India for many centuries, and a large percentage of the market is supplied by native goods.

NATIVE MANUFACTURE

Upon arrival at the factory the sticklac or grainlac is ground in hand-operated mortars to remove from the sticks and to such a mesh as requires that the individual cells be broken open to free the remains of the inclosed insect. It is then sifted through a hand sieve. These operations are shown in Fig. 7. The products are here separated into three classes: (1) Granular lac, known by the trade name of seedlac; (2) fragments of branches and twigs, which are often used as fuel; and

lac is boiled in a solution of crude sodium carbonate and borax, or rubbed in water with alum, and strained through a cloth, repeating until all the dye is removed.

In some cases, as in Hyderabad, the grainlac is mixed with potash, dry, and bleached in the sun. All the methods have the one object, that of removing the red dye.

Where adulterants are to be employed they enter the process at this point. Orpiment (As_2S_3) or rosin (im-

FIG. 5. LEFT—TRANSVERSE SECTION OF FEMALE LAC CELLS. RIGHT—LONGITUDINAL SECTION OF SAME

FIG. 4. FROM LEFT TO RIGHT—DEAD FEMALE CELL WITH YOUNG EMERGING, 4 TIMES ENLARGED. WINGLESS MALE, 12 TIMES ENLARGED. WINGED MALE, 40 TIMES ENLARGED. MALE CELL, 15 TIMES ENLARGED. FEMALE CELL 13 WEEKS AFTER INOCULATION, 15 TIMES ENLARGED

(3) fine dust, which consists of small fragments of lac and dirt known as Khud, which is sold to makers of trinkets and toys.

The seedlac is next washed, undergoing a soaking for about twenty-four hours, and is again ground to insure the breaking up of individual cells. It is desirable to wash out thoroughly the included organic matter. The wash water takes on a deep purple color due to the dye. A residue of dirt and fine lac is recovered from the wash water and sold to native bangle makers under the name of Gand. The washing process is shown in Fig. 8. After washing, the seedlac is exposed to light and air on drying floors, where it bleaches to some extent.

There are several variations of this method where lac is prepared for local consumption in the distant provinces away from the factories. In the Punjab the

ported from North Carolina), or sometimes both, are mixed with the seedlac. The orpiment is used to impart a rich pale straw color to grades where a light color is required. The garnetlac and other darker grades will usually be free from this arsenic adulteration.

Rosin is added to lower the melting point of the seedlac so necessary in the next step of the process, and a certain amount is recognized as being necessary in the native operation. Rosin, however, in quantities, causes cracking and flaking in the final varnishes. The resiliency, or bending quality, is one of the valuable physical characteristics of pure shellac.

It is the practice of unscrupulous makers to add rosin in proportions as high as 20 per cent during high

FIG. 6. HARVESTING STICKLAC

markets. Specifications should demand rosin content of less than 3 per cent for native commercial grades.

The mixture of seedlac and adulterant is placed in cloth bags about 12 ft. long and 2 in. in diameter. These bags are held before open furnaces heated by coke and charcoal fires, with a native at each end of a bag. Fig. 9 shows a view of the fireplace and Fig. 10 the melting and stretching operation.

As the contents of the bag begin to soften in the

portion directly before the fire, the bag is twisted, squeezing the melted material through the mesh. Occasionally a reverse twist is given to one end of the bag, causing an emptied portion to coil up. The bag is drawn steadily forward until all portions have been before the fire and the contents exhausted.

The melted lac drips to the floor. Any portions not sufficiently melted are recovered and remelted. The warm and partly molten lac is picked up by a third native, who stretches it into thin sheets by placing a foot on either end of a strip and pulling the center upward before the body. Variations of this action eventually bring the shellac to thin sheets or flakes, the form seen on the market.

The sheets are examined and sorted as shown in Fig. 11. All dark-colored or dirty portions are broken off and returned for remelting. Parts not bleached and of a red color are sorted as the garnetlac. Button lac is made from certain qualities cast in the form of buttons about $1\frac{1}{2}$ in. in diameter. The finer and lighter qualities are graded with the orange shellacs. They contain the greater percentages of the adulterants.

After the bags are empty they are boiled to remove the residue, known as Kiri or Phog, from which inferior shellacs are made. These are cast in slabs about 6 in. in diameter and 1 in. thick and sold to makers of bangles, sealing wax and similar articles.

MACHINE PROCESSES

The aboriginal method of manufacture has been much improved upon in recent years by the machine methods. These are employed by only one firm, as far as we know, however, and have not displaced the native methods of other makers because of the secrecy surrounding the design of machinery.

The sticklac and grainlac are fed to mechanical grinders, and steam enters largely into the washing and

FIG. 8. WET REFINING

melting operations. The processes are refined to such a point as to shorten the time and increase the production enormously.

The one European concern with factories in Calcutta is said to have between five and six times greater capacity of production than any native producer. About 10 per cent of the total shellac exported from India is machine refined.

The basic difference between native and machine made shellac is the uniformity of the quality and difference in insoluble matter. The insoluble matter in native goods varies from $1\frac{1}{2}$ per cent in the finest grades to 5 per cent in the lower grades. The machine made goods, however, never show more than 0.50 of 1 per cent insoluble matter and go as low as 0.20 of 1 per cent. The chemical analyses given further in this article will illustrate this more clearly.

GRADES OF SHELLACS

There are two general classifications or grades of shellac: (1) Orange shellac and (2) garnetlac. Button lac is a sub-division of orange shellac. The qualities of orange shellac are determined principally by color and to a less degree by freedom from dirt, insoluble matter and rosin. Garnetlac comes only in the form of flakes, but in many qualities.

The popular native marks of shellacs in the order of their value and quality are as follows:

D C
V S O
Diamond I
Double Triangle G
Superior
Superfine
Fine
Good
T N (Truly Native)

These are all orange shellacs. The first four are called standard marks, each made by a separate native manufacturer.

The terms Superior, Superfine and Fine are simply descriptive, and in order named range from light to less light qualities down to T N, which is the lowest and darkest grade.

There are corresponding grades of machine-made shellacs. Of these grades, which are given under trade names of the maker,¹ the garnetlac is the superior grade where highest content of lac resin is required, regardless of lac, wax and color.

FIG. 7. GRINDING AND SIEVING

¹Angelo Bros., Calcutta, India.

CHEMICAL ANALYSES

Shellac consists of lac resin itself, which is the gum shellac; a certain amount of so-called lac wax, a hard whitish or brownish substance more like carnauba wax than any other; a small percentage of moisture and the insoluble matter, which is, speaking generally, either organic matter, the remains of the lac insects, and so-called residue of vegetable, mineral or other substances. Average analyses of high-grade native hand-made goods run about as follows:

	Per Cent
Lac resin.....	93 to 94
Lac wax.....	3 to 4½
Moisture.....	1½ to 2
Insoluble matter, of which the organic matter is usually two-thirds.....	1 to 2

Low-grade native hand-made shellacs analyze about as follows:

	Per Cent
Lac resin.....	91 to 93
Lac wax.....	3½ to 4½
Moisture.....	1½ to 2½
Insoluble matter, of which the organic matter is usually two-thirds.....	2½ to 4 or even 5

The average analyses of machine-made shellacs vary only slightly and run about as follows:

ORANGE SHELLAC

	Per Cent
Lac resin.....	95 to 96
Lac wax.....	3 to 4
Moisture.....	1½ to 2½
Insoluble matter.....	0.2 to 0.3

GARNETLAC

	Per Cent
Lac resin.....	97.7
Lac wax.....	0.5
Moisture.....	1½ to 1.6
Insoluble matter.....	0.2 to 0.3

It is of course understood that the shellacs above mentioned are free from rosin. If rosin is added, cut down the percentage of lac resin in exact percentage to the amount of rosin.

The analyses of a large number of samples of crude lacs by Dr. D. Hooper for the Indian Forest Service have been averaged into the following table:

Name of Tree	Water	Rosins	Coloring Matter	Residue	Ash
Kaum (Schleichers trijuga).....	1.8	85.6	2.5	9.1	1.0
Ficus.....	1.8	83.9	2.6	10.2	1.5
Ber (Zizyphus jujuba).....	2.0	82.7	2.4	11.5	1.3
Palas (Butea frondosa).....	2.4	77.4	4.3	14.1	1.8

CHEMICAL COMPOSITION OF SHELLAC

Analysis of commercial D C shellac made by H. Endemann shows on treating with a caustic alkali solution a

FIG. 10. MELTING AND STRETCHING

residual wax having a carbon content of 82.18 per cent and hydrogen 14.25 per cent. A complete analysis of the above gave the following:

- 4.5 per cent myricyl alcohol.
- 8.0 per cent non-condensable acids (not oxyacid) and impurities
- 27.0 per cent soluble and crystallizable oxyacid.
- 60.5 per cent oily oxyacid, only slightly soluble.

PURE SHELLAC

Dry shellac for use in coatings in the United States Navy has been purchased for a long period of time on the following general specifications:

ORANGE GUM SHELLAC

Grade A Quality.—1. *For pattern and varnish work.* To be of a grade similar in quality to the brand known commercially as "Double Triangle G," and must be freeable by hand without the use of any tools. When treated with hot 95 per cent alcohol, the residue of insoluble matter must not exceed 1½ per cent and the shellac must be free from rosin and other adulterants. All deliveries must be equal in color and in all other essential respects to the standard sample of this grade of shellac.

Grade B Quality.—2. *For coating linoleum-covered decks.* To be of good quality and must be freeable by hand without the use of any tools. When treated with 95 per cent hot alcohol, the residue of insoluble matter must not exceed 3 per cent. It must be of one of the following two qualities: (1) Free from rosin and have an iodine number of less than 18 as determined by method of subcommittee on shellac analysis (*Journal of the American Chemical Society*, pp. 1221 and 1227, Vol. 29, No. 8, August, 1907); or (2), the grade known commercially as "U. S. S. A. Standard T N," containing not more than 3 per cent rosin. The grade of shellac known as "New York Standard 3 per cent" will not be accepted. Deliveries of rosin-free shellac and "U. S. S. A. Standard T N" must in all essential respects be equal to their respective standard samples of these grades.

Grade C Quality—Garnetlac.—3. *Garnetlac for coating linoleum-covered decks.* To be of good quality and ground fine enough to be readily soluble in alcohol. When treated with 95 per cent hot alcohol the residue of insoluble matter must not exceed 1 per cent. To be free from rosin and have an iodine number of less than

FIG. 9. FIREPLACE

18, as determined by method of subcommittee on shellac analysis, referred to above. All deliveries must be equal in all essential respects to the standard sample of this grade of shellac.

These specifications probably cover the situation where a coating of good mechanical and physical properties is desired.

NEARLY CHEMICALLY PURE SHELLAC

If a covering is required where the shellac is to be subjected to electrical stresses or certain chemicals, and for special mechanical uses where flexibility is a feature, the specifications must be somewhat different.

During the period just past it became necessary to draw up specifications for shellac with which the interior of explosive shells might be coated to resist the action of new explosive chemicals on the steel body and to present a smooth tough surface which would cause little friction when the shell was whirling through the air, in case the cast charge became loosened in its container. In case of failure either the chemical action or the friction of charge against steel might cause premature explosion of the shell.

The first procedure was to send a number of samples of mixed varnish to the laboratory from a selection that had been passed on by commercial chemists as being satisfactory for the purpose. Results from two of these analyses were as follows:

SAMPLE MARKED "No. 1"	
Acidity.....	Shows distinct acid test within a minute.
Ash.....	0.6 per cent. Contains manganese, zinc, iron, aluminum, calcium.
Flash point.....	Below 20 deg. C.
Action of picric acid.....	No action after 5 days' contact.
Time of drying.....	Fifteen minutes.
Covering quality.....	Covers well but dries too quickly for satisfactory brushing.
Hardness and adherence.....	Coating brittle, adherence poor. Does not pass the knife or hammer test.
Bending test.....	Cracks and flakes badly upon bending.

This sample does not comply with tentative specifications for interior shell coatings because of the poor adherence on steel, and presence of objectionable metals. Also on account of failure to pass acidity test.

SAMPLE MARKED "No. 3"	
Acidity.....	Distinct acid test within one minute.
Ash.....	0.3 per cent. Contains zinc, calcium, aluminum, iron (trace).
Flash point.....	Below room temperature (70 deg. F.)
Action of picric acid.....	No action after 5 days' contact.
Time of drying.....	Ten to fifteen minutes.
Covering quality.....	Covers well, but dries too quickly for satisfactory brushing.
Hardness and adherence.....	Coating brittle, adherence poor. Does not pass knife or hammer test.
Bending test.....	Cracks and flakes badly.

This sample does not comply with tentative specifications for interior shell coatings, because of poor adherence on steel and presence of objectionable metals. Also on account of failure to pass acidity test.

The results of these tests show without doubt that the samples were of the usual mixed varnish type heavily loaded with rosin and of a poor grade of shellac.

METHOD OF TESTING

Shellac varnish analyses are rather difficult to run for impurities and chemical properties, so it was decided to test the ingredients for purity before mixing in the varnish and then try out for performance under as near service conditions as possible. The following procedure was followed with a number of samples with the purpose of ascertaining the reaction of various explosives upon shell protective coatings and the an-

alysis of them to ascertain if they are true to name, and contain no undesirable metallic elements.

The explosives used were:

TNT
E L 104 (du Pont)
Nitro starch (du Pont)
Amatol (80-20) Picatinny Arsenal
Amatol (50-50)
Sodatol (80-20)
Ammonal
Picric acid
Ammonium nitrate

Experimental shells were made by machining one-inch pipe caps until the inside was bright and smooth and then coating the interior with the lacquer to be

FIG. 11. INSPECTING SHELLAC

tested, some by brushing, and others by pouring in the lacquer, turning cap around to insure complete coating, and then inverting to permit the excess of lacquer to run out. (This gave a heavy coating.)

The caps were loaded reasonably full of the various explosives and put in an oven at 50 deg. C. for one week. At the end of the period they were unloaded and the condition of the film in the cap interiors was carefully noted. Results are shown with one sample as follows:

TNT—Film glossy, good condition.
E L 104—Film glossy, good condition.
Nitro starch—Film glossy, good condition.
Amatol, 80-20—Film glossy, good condition.
Amatol, 50-50—Film glossy, good condition.
Sodatol—Film glossy, good condition.
Ammonal—Film glossy, good condition.
Picric acid—Film glossy, good condition.
Ammonium nitrate—Film glossy, good condition.

Hot loading—thick film (poured):

TNT—Sweat out at upper edge of cup. Film unaffected.
Picric acid—The P.A. binds tightly to the lacquer. Film unaffected.

FINAL SPECIFICATIONS FOR PURE SHELLAC VARNISH

After investigation and research extending over a period of several months a specification was prepared, and it is believed that use of the abstract of this, given below, will secure the purest shellac varnish commercially obtainable. Special applications must always be considered.

Varnish to be entirely free from alkali, mineral acids or volatile organic acids. Test to be made by thoroughly shaking approximately 20 grams of sample with 50 cc. of neutral distilled water, continuously for ten minutes. Then test with neutral litmus paper. If no change oc-

curs in three minutes the amount of acid or alkali is negligible. If either acid or alkaline reaction occurs the varnish will not be accepted.

Varnish to be entirely free from heavy metallic oxides for driers or any other purpose, except traces of iron oxide, lime or silica.

Varnish shall contain no nitrocellulose or any nitrated material.

Varnish must adhere firmly and when dry shall present a heavy, firm, tough, glossy coating which will not crack, peel or flake.

Varnish shall be mixed as follows:

Shellac	4 lb., 1 oz.
Alcohol	1 gal.
Turpentine	1/20 gal.

Shellac or garnetlac, used in the above formula, shall conform to the following specifications:

To be good quality and ground fine enough to be readily soluble in alcohol.

When treated with 95 per cent hot alcohol, or tested in an alcohol insoluble apparatus for shellac, the residue of insoluble matter shall not exceed 1.75 per cent.

Must be free from rosin and have an iodine number not more than 18, as determined by method of subcommittee on shellac analysis (*Journal of the American Chemical Society*, pp. 1221 and 1227, Vol. 29, No. 8, August, 1907).

Moisture must not exceed 1.75 per cent.

Ash must not exceed 1.5 per cent.

May be any color.

Alcohol, used in above formula, must be either 188 proof completely denatured or 190 proof specially denatured.

Turpentine, used in above formula, to conform to following specifications:

Quality—The turpentine shall be (1) either a properly prepared distillate from pine oleo-resins, commonly known as gum turpentine or spirits of turpentine; or (2) that obtained from resinous wood by extraction with volatile solvents, by steam, or by destructive distillation, and commonly known as wood turpentine.

The turpentine shall be clear and free from suspended matter or water.

The color shall be water white.

The specific gravity shall not be less than 0.860 or more than 0.875 at 15.5 deg. C.

The initial boiling point shall not be less than 150 deg. C. or more than 160 deg. C.

Ninety (90) per cent of the turpentine shall distill below 170 deg. C.

The polymerization residue shall not exceed 2 per cent and its refractive index at 15.5 deg. C. shall not be less than 1.500.

Tests. Tests of ingredients shall be made by an inspector before mixing to form varnish, and the mixing of approved materials shall be witnessed by the inspector. The finished product shall then be tested for proof under the first part of this specification.

SHELLAC MARKETS

The shellac market is highly speculative, due to the wide variety of factors which have been seen to enter into the production. During recent months a great scarcity has caused the price to rise above a dollar a pound. Before spring, however, the importers predict, the best grades may be obtained at fifty cents per pound.

A free market condition is said to be desired by all, and for this reason the shipping season commences in early November and ends in May. With June the rainy season and the combination of moisture and intense heat endanger this free condition. From June to September, therefore, only lower grades are exported. The bulk of the shellac comes from Calcutta via Indian

Ocean, Red Sea, Suez Canal, Mediterranean Sea to European and U. S. Atlantic ports. A portion goes to China and Japan to be shipped to American Pacific ports.

INDUSTRIAL USES

This substance has a very wide application in both the dry and varnish forms. As a molded product it is used in buttons, phonograph records, emery wheels, toilet articles, insulations, mica products, oilcloths, linoleums, sealing wax, hats, fireworks, paper, etc. As a varnish its applications are too numerous and well known to require mention.

Each particular requirement must be met by a thorough analysis of the conditions surrounding its use. Where purely ornamental purposes are to be served it is economical to employ the cheaper grades. Here color is usually the determining quality. When the chemical purity and mechanical strength are involved and the color is not material, the garnetlac grades are found to serve best.

We especially appreciate the assistance of Mr. D. W. Mulford in the preparation of this article.

Mineral Leasing Bill

The general mineral leasing bill again is in conference, with bright prospects for an early agreement. This measure, which has a direct effect on 700,000,000 acres of public land and directly involves 6,500,000 acres of possible oil land, 70,000,000 acres of coal lands, 2,700,000 acres of phosphate land and 3,500,000 acres of oil shale land, has been under consideration in Congress for seven years. This is the fourth time the leasing bill has been passed by the House.

The House refused to allow the embodiment into this bill of the section of the Senate bill which would modify the decree of dissolution against the Standard Oil Co. of New Jersey. It also refused to embody in this bill the section of the Senate bill which provides that corporations engaged in producing or refining petroleum shall maintain the same price for their products where the stockholders of any one of such corporations own or control 25 per cent or more of the stock of any other of such corporations.

The House committee recommended that the fund accruing from leases should be divided as follows: 45 per cent to the Reclamation Fund, 45 per cent for the State and 10 per cent for the Federal Government. This was changed on the floor of the House, however, so that 70 per cent of the fund from past production would go to the Reclamation Fund, 20 per cent to the State, and 10 per cent to the Government. For future production 60 per cent is to go to the Reclamation Fund, 30 per cent to the State, and 10 per cent to the Government.

A provision in the House bill reserves helium production for the Government. While objection was made to this provision as being over-protection, it was allowed to stand mainly on the advice of the War Department that helium could be extracted from natural gas without interfering with oil or gas operations.

Development of American Research*

BY VLADIMIR KARAPETOFF

FAR be it from me to urge greater emphasis upon research in our universities simply for reasons of national safety or because of advantages in competitive foreign trade. I shall not even urge it because of its evident importance in medicine, agriculture, engineering or government. No, I believe that our enlightened public opinion should rise to a point where it will demand recognition and support of investigators in pure mathematics, in theoretical physics and chemistry, in the study of nature and man, in philosophy, languages and literature, in fact, in any branch of human activity, no matter how remote a subject of investigation may be from our bread-and-butter problems. If we are to profit permanently by research—I am almost tempted to say if we are to become like older civilized nations in this respect—we must give up “practical” and mercenary ideas on research, and promote research for its own sake. It is like unto the Biblical precept that we must give up the ordinary sense of life in order to find the higher sense of life.

PURE RESEARCH SHOULD THRIVE IN UNIVERSITIES

There are many good reasons for which pure research should thrive in universities; in fact, great universities in Europe are considered natural centers of higher learning and investigation. This function of the universities is not always clearly understood in this country even by persons upon whom their administration and support are dependent. A teacher in elementary subjects need not necessarily be an original investigator or deep scholar. If he is a “big brother” to his students, he can introduce them successfully into the intricacies of elementary chemistry or French 1 and leave a beneficial lasting impression upon their forming characters. But a professor of an advanced subject must be at least a fairly deep scholar if not an original investigator of first magnitude. Only then can he enthuse his students and open before them wider vistas, that inspire both for knowledge and for action. It used to be an education in itself to sit at the feet of Lord Kelvin or Von Helmholtz.

MEN OF HIGH CALIBER LOST TO THE WORLD

The situation is this: Men of such high caliber sometimes do not find their real power until later in their lives. In the meanwhile the lure of the industrial world, of consulting practice, or text-book writing, too much elementary teaching, lack of literary work, lack of laboratory or library facilities, scarcity of research assistants, no appreciation, no place to publish the results of their research, financial worry, and lack of opportunities to travel and to meet fellow workers in other institutions or at conventions—all these factors dull their brilliant powers and bring an irreparable loss to the whole world. These men have no unions, no spokesmen, no influential organs of their own; they valiantly fight their battles each for himself, and they die at their posts meek, faithful and unheard of.

We hear too much about lack of university buildings, and an impression is sometimes unconsciously conveyed that the principal problem is to get more buildings. But I say that much brilliant pioneer work by men like

Bunsen or Faraday has been done with most meager possible facilities. A good laboratory tends to encourage purely experimental research at the expense of analytical thinking and deeper interpretation. Curves, tables, experimental data of all kinds, are being published in an alarming quantity by mediocre men who have easy access to laboratory facilities. What we need in this country is more scientific men of prophetic vision, interpreters of the world, men of superior analytic and synthetic power who need no marble halls for their creative output; but such men grow only on a fertile soil, with a background of research and appreciation of culture behind them. These superior men step out of the background of a large number of less-gifted investigators and they lean upon those left behind for data, for companionship and for appreciation and approval.

As far as the higher form of university life is concerned, that is, research, what we need the most in this country is the correct attitude. Money, facilities and results will come in due time. This correct attitude may be summarized as follows:

CORRECT ATTITUDE SUMMARIZED

1. Consider all scientific research, no matter how theoretical and remote from practical ends, to be a necessary and important factor in the life of a civilized country and the mainspring of its healthy progress.
2. Research has to be multiplied a hundredfold in all its forms, as is the case in Germany, so that every young American investigator could easily find his place and problem, and would not feel like the sole survivor of a sunken bark.
3. Do not expect immediate tangible results from a newly established research center any more than you expect them from a recently planted orchard. Take good care of it and it will bear abundant fruit in due time and for many years to come.
4. Provide living salaries for younger teachers in universities, in order to be reasonably sure of securing a large number of promising young men, who later may develop into research stars of different magnitude.
5. Do not lay undue emphasis upon experimental facilities and investigations. This country is markedly deficient in high-grade analytical thinkers, capable of sublime generalizations in science. No effort should be spared in seeking out and developing such men, and placing them under working conditions under which they can give to the world their best.

Registration of Engineers in Iowa

It should be generally known that a law was passed by the last General Assembly of the State of Iowa requiring registration of all professional engineers and land surveyors and providing in Section 10 for their registration by Jan. 4, 1920, upon their professional qualification without examination. From Jan. 4 to July 4, 1920, registrations will require a technical examination before the Board. After July 4, 1920, practice in the State of Iowa without a registration certificate will be a punishable offense. The penalty imposed for such offense will be a fine of not less than \$100 or more than \$500. Application for registration, copy of law and instructions, from K. C. Kastberg, secretary Iowa State Board of Engineering Examiners, Box 923, Des Moines, Iowa. Other members of the Board are Seth Dean, L. M. Martin, F. W. Stubbs, and Alvin Le Van.

Potash Recovery From Blast-Furnace Gases in England

A Description of Potash Recovery as Carried Out in Connection With English Blast-Furnace Operations, Together With Notes on the Activities of the Potash Production Bureau in Cement Dust and Other Fields

By HAROLD HIBBERT

SOON after the outbreak of the European war in 1914, the British Government found itself in a precarious position in so far as the available supplies of potash were concerned, since up to that time the greater part of these had been obtained from Germany. As is well known, this product is used in connection with fertilizers and explosives, and also forms one of the basic raw materials for the manufacture of glassware. As the war progressed, the home manufacture of special optical glass for various scientific instruments, such as field glasses, microscopes, lenses, prisms, etc., became a matter of prime importance, hence a domestic supply of potash became imperative. Prior to 1913, the pre-war requirements of potash (potassium chloride) in the various countries were estimated¹ to be roughly as follows:

	Tons
United Kingdom of Great Britain and Ireland.....	35,000
United States and Canada	300,000
France.....	50,000
Italy.....	50,000
Germany.....	600,000

Thus it became necessary to devise some means of finding new sources of this material. The British Government created a special government department known as the Potash Production Bureau, which was attached to the Ministry of Munitions, the function of which was to stimulate potash production.

Of the various schemes submitted to the Bureau, the one which appeared to offer the most promising prospects for quick development and production was that in connection with the recovery of potash from the dust carried over in blast-furnace gases. Experiments carried out prior to 1914 at the plant of the North Lincolnshire Iron Co. served to indicate that this dust contained considerable quantities of potash salts, and as a result of the data submitted a company was formed, known as the British Potash Co., Ltd., with a capital of £100,000, of which the British Government supplied £50,000, thus becoming the owner of one-half the stock. The remainder was subscribed for by the British Cyanide Co. either directly or indirectly through their friends, especially those connected with the North Lincolnshire Iron Co., at whose plant the first large-scale experiments were performed. Considerable experimentation and research work have since been carried out both in the laboratory of the British Cyanide Co. and in connection with the various blast-furnace installations. It was decided by the British Potash Co., Ltd., that the most rational policy to adopt would be to have one central collection depot to which the potash dust from the various blast-furnace plants could be shipped for the extraction of the potash content, and in furtherance of this idea, a plant was erected at Oldbury on land adjoining that owned by the British Cyanide Co., where all the

recovered blast-furnace potash dust is now being "treated."

TECHNIQUE EMPLOYED IN THE RECOVERY OF POTASH DUST FROM BLAST-FURNACE GASES

The principal incentive to the earlier study of the removal of potash dust from the blast-furnace gases was not primarily the recovery of potash, but the great economic advantage to be obtained in the saving of fuel effected by using such "cleaned" gases in connection with pre-heaters, economizers, steam boilers, etc. Thus it has been shown in actual practice that using a cleaned gas—namely, one from which the dust has been removed—the stove surface area for pre-heating the air-blast can be reduced in the ratio of 3 : 5 as compared with gas from which the dust has not been removed. Furthermore, in the utilization of a "dust-free" gas in connection with economizers or gas engines a much-increased efficiency is obtained, resulting in the elimination of considerable boiler capacity, with the further advantage that it is no longer necessary to keep one or more boilers out of commission for cleaning purposes. It has been proved definitely that freeing the gases from dust undoubtedly results in a large saving of the coal employed for power purposes. When the question of finding the most efficient method for removing the dust came up for discussion, it is understood that the well-known Cottrell process of electrostatic dust precipitation was favorably considered, but that, owing to various reasons not fully understood, attention was focused on the Halberg-Beth bag system of dust collection. This is a German-patented process which was taken over by the British Potash Co., the method consisting in bringing about a primary deposition of the coarser dust particles in large iron chambers fitted with a simple "baffling" device which takes out coarse and medium-sized particles, after which the hot gases are filtered through long cotton bags arranged in iron chambers. These bags are provided with a mechanical shaking arrangement for throwing down the dust in order to prevent clogging. In this way the fine dust is collected separately from the medium and coarse. It is found that the heavy coarse dust contains 2 to 3 per cent soluble potash, the medium 3 to 10 per cent, and the fine dust which collects in the bag 10 to 50 per cent. The fine dust (and in those cases in which the potash content warrants it, also the medium sized dust) is then shipped to Oldbury for treatment.

In the bag-house system of dust collection it is obviously important that the temperature of the blast-furnace gases (which issue at about 500 deg. C.) should be reduced to 125-150 deg. C. in order to prevent the cotton bags from being destroyed. The maximum temperature thus must not exceed 150 deg. C., while on the other hand care must be taken that it does not fall below 125 deg. C., since otherwise moisture will be deposited, and clogging will take place. It is evident that considerable

¹Chemical Age, July 19, 1919. This does not take into account the salts, such as the sulphate, etc.

care is necessary to prevent any sudden rush of hot gas, since such might bring about the destruction of the entire bagging equipment. Apparently no steps have been taken to decrease the inflammability of the bag material, although a suggestion has been made to impregnate with either ammonium tungstate or silicate of soda solution. It is claimed that the "bag" should last for about twelve months' continuous operation before renewal is necessary.

TREATMENT OF THE POTASH DUST

The treatment of the potash dust consists in a simple lixiviation of the material with water (mother liquor from a previous run is employed), the resulting sludge being separated by the use of an Oliver filter. The solution is evaporated, allowed to crystallize, and centrifuged, the product thus obtained containing 80 per cent soluble potash in the form of chloride. No chemical treatment is necessary at any stage of the purification process.

The following typical analysis shows the content of an average sample of the finished product:

	Per Cent.		Per Cent.
KCl	72.16	H ₂ O	12.36
K ₂ SO ₄	6.65	Insol.	0.25
NaCl	8.56	KCN	0.10
			100.08

It is of interest that the iron ores occurring on the east coast of England contain sufficient chlorides in the original iron ore to insure all the potash volatilizing in the form of chloride, while those on the west coast contain a little sulphur, so that a small amount of sulphate is obtained.

METHOD OF INCREASING THE POTASH RECOVERY

Experiments carried out by the British Potash Co., Ltd., have shown that the addition of a small amount of common salt to the blast-furnace charge in certain cases increases the yield of potash obtained (British Patent 112,338) which is especially true of ores relatively free from chlorides, and from which in consequence a considerable quantity of the potash would otherwise find its way into the slag. This applies to those ores occurring on the west coast of England, and also to certain Welsh ores.

In one or two instances it has been found that the recovered potash salts may contain a small amount of cyanide, in which case it is necessary to remove the latter by a special process of recrystallization.

LIST OF POTASH RECOVERY PLANTS IN OPERATION

There are at present three blast-furnace plants collecting dust in bags for the recovery of potash, namely, North Lincolnshire Iron Co., Palmers Shipbuilding & Iron Co., and Ebbw Vale Iron Co. In each of these plants common salt is added to the blast-furnace charge to increase the potash yield. In addition to these, four other blast-furnace plants, viz., Blaenavon Iron Co., South Wales; Barrow Hematite Co.; Baldwin's, Ltd., South Wales, and Millom & Askam, Cumberland, are being equipped with similar installations, while the Ebbw Vale plant has commenced the erection of a second unit.

COST OF ERECTION AND OPERATING

It is claimed that it is not economical to build an operating unit of bags capable of handling more than 1,000,000 cu.ft. of gas per hr., the present cost of such an installation being £40,000 (approximately \$200,000).

No definite statement could be obtained as to the actual cost of operating, but it would seem that the labor cost and the necessary operating power are both higher than in the case of a Cottrell installation.

RECOVERY OF POTASH BY THE LODGE FUME CO. PROCESS

The Lodge Fume Co. has been formed to develop certain patents (for dust recovery from gases) granted to Sir Oliver Lodge, on lines closely related to those of Cottrell, and following the successful small-scale experiments a large plant is now in process of erection at the Skinningrove Ironworks, Yorkshire, which was expected to be in operation in August. It has been designed to treat the entire output of 4,000,000 cu.ft. of gas from the usual closed-top blast-furnace working on local ores, no salt addition being necessary in this case.

The equipment has apparently been planned on somewhat similar lines to the well-known Cottrell installations, namely, a series of vertical iron plates with rods placed centrally. It is intended to operate at 70,000 volts, 7 to 10 hp. being required to run the system. The annual output of potash is expected to amount to not less than 1000 tons of 80 per cent material, and the iron company proposes to erect its own refining plant. It is anticipated that not more than two men and two boys will be required to operate the entire plant.

COST OF INSTALLATION

This plant, which is designed to treat 4,000,000 cu.ft. of blast-furnace gas per hour, is estimated to cost £35,000, as compared with £40,000 for a single unit of the bag system capable of handling only 1,000,000 cubic feet.

RECOVERY OF POTASH BY THE COTTRELL PROCESS

An experimental Cottrell plant was installed in 1918 by Huntington, Heberlein & Co., Ltd., the British representatives of the International Precipitation Co., at the works of the Workington Iron & Steel Co., Ltd.

Certain alterations in the design were soon found necessary, and these were subsequently carried out, though there was considerable delay owing to difficulties connected with the supply of labor and materials. The reconstructed plant comprises thirty-six 12-in. pipes 15 ft. long, and arrangements have been made so that the blast-furnace gas can be tapped from the main without interfering with the operation of the boiler plant.

The experiments at Workington were the first to be carried out in England on a comparatively large scale, and as is usual under such circumstances, many experimental difficulties inherent to this particular proposition had to be overcome. With the knowledge so obtained, it is now claimed that it will be possible to erect plants of any size required which will operate with an efficiency of 90 per cent or better.

COMPARISON OF THE BAG AND ELECTRIC SYSTEMS OF POTASH RECOVERY

The outcome of the Skinningrove and Workington experiments is awaited with considerable interest in order that a direct comparison of operating costs may be made between the electrical method of potash recovery and the Halberg-Beth bag system of dust collection. From the above facts it would seem that the cost of equipment and installation of the latter process is roughly four times that of the former, and the operating charges are also apparently higher, due to the increased labor charges and the higher depreciation. Also, the horse-

power necessary to force the hot gases through the filter system is much greater than that required to operate the electrical installation.

In view of the pronounced success of the companies operating the Cottrell system of recovery in connection with cement plants in America, there would seem to be little or no doubt that an equal measure of success would be achieved in connection with the recovery of potash from blast-furnace gases.

No definite information could be obtained as to the present cost of production of 80 per cent muriate of potash, but in view of the increased output in this field and the number of new installations, together with the fact that one plant is already installing additional equipment, the claim of the British Potash Co. that it expects to be able to produce this material at prices low enough to compete with German potash would seem to provide a sufficient stimulus for the large iron and steel companies in America to undertake similar experimental developments.

It is evident from the analysis of typical English ores, quoted below, that the American ores in many cases contain even larger quantities of potash, so that American iron and steel producers should be in a position to achieve equally valuable commercial results.

POTASH CONTENT OF TYPICAL ENGLISH IRON ORES

The ores on the west coast contain roughly from 0.2 to 1.30 per cent of potash calculated as chloride of potash, an average sample of the flue dust analyzing approximately as follows:

	Per Cent		Per Cent
Insoluble matter.....	82.10	Sodium chloride.....	1.9
Potassium chloride.....	7.82	Water.....	8.0

Those on the east coast contain a potash content varying roughly from 0.2 per cent to around 1.5 per cent calculated as chloride of potash, equivalent to 1.3 to 0.95 per cent K_2O . A typical "flue dust" analysis showed:

	Per Cent		Per Cent
Soluble potash.....	55.3	Calcium carbonate.....	10.4
(Calculated as KCl).....		Silica.....	8.9
Sodium chloride.....	4.0	Magnesia.....	1.0
Ferrie oxide (Fe_2O_3).....	11.7	Carbonaceous matter, etc.....	6.5
Zinc sulphide.....	2.2		100.0

The potash (K_2O) content of English iron ores may thus be said to vary between 0.126 and 0.98 per cent as compared with American iron ores, which average from 0.29 to 2.07 per cent, according to a large number of analyses run by Mr. N. C. Gellert of the Gellert Engineering Co., Philadelphia, Pa.

RECOVERY OF POTASH IN CEMENT PLANTS

While in England special emphasis has been laid on the extraction of potash from blast-furnace gases, considerable experimental work has also been done on the recovery of potash from the dust in the gases from cement kilns. The somewhat slower industrial development is probably due to the greater activity and interest shown by the blast-furnace operators and the evident fuel economies which can be effected by the use of a dust-free gas. On the other hand, little or no use is at present made of the latent heat in the waste gases from cement kilns, so that this consideration did not, of itself, make the same striking appeal to the English cement manufacturers. An experimental installation is already in operation in connection with the gases from a cement plant operating the wet mix method, in which the bag system of dust recovery is employed, and arrangements have been completed for the installation of a recovery plant in connection with a new modern cement plant of 1600-bbl. capacity, also

operating the wet mix process. The type of recovery apparatus to be employed will be definitely decided upon after the relative cost of potash production by the bag system, as compared with the electrical process, has been definitely established. There is reason to believe that rapid progress will be made in this field during the next few years.

PREDICTION OF BRITISH INDEPENDENCE IN THE POTASH FIELD

The Potash Production Bureau of the British Board of Trade is convinced that by the utilization of both sources of production the country will be made entirely independent of outside sources of potash.

While undoubtedly much greater progress has been made in America with respect to economies to be effected in the cement industry by the utilization of the latent heat in the waste gases as well as in the recovery of potash from the dust, there would seem no reason to doubt that much of the gas from blast-furnaces can be similarly treated with correspondingly favorable results from the fuel standpoint as well as from that of potash recovery. The way, in fact, has already been pointed out in the admirable papers by Messrs. Wysor,¹ Gellert,² and Bradley,³ and it now only remains for the iron and steel manufacturers to take advantage of the pioneer work already carried out by Cottrell, Linn Bradley, Wysor, Gellert and others (of whom the scientific and technical work of Linn Bradley, Research Corporation, New York, calls for special mention) to make America economically independent of outside sources of potash production.

STIMULATION TO INTEREST HERE

The fact that the average American iron ore contains on an average as much as or even more than the average English iron ore should serve considerably to stimulate interest in this matter. Of special interest too are the large deposits of brown hematite ores in Alabama, which are remarkable for their high potash content. By the use of these ores (with possibly salt addition) in ordinary blast-furnace practice and employing the Cottrell process for the recovery of the potash in the dust, it does not seem any exaggeration to assume that the necessary supplies of potash for the entire fertilizer requirements of the South could be provided from this source. Furthermore, the experimental work already carried out by Gellert with manganese ores shows that they contain a much higher potash content than iron ores, and his suggestion that a start should at once be made with such material would seem to represent a sound well-balanced judgment. We understand, in fact, that such a scheme, under his supervision, and with the active co-operation of the Research Corporation, New York, is already under way in one locality.

CONCLUSION

According to information supplied by the Bureau of Potash Production, England, large-scale experiments on the recovery of potash from blast-furnace gases have shown that:

1. By the removal of the dust from blast-furnace gases, the pre-heating surface for the air blast can be reduced in the ratio of 3 : 5.

¹Bull. Amer. Institute Mining Engineers, 1917 (Jan. 17), with subsequent discussions.

²CHEM. & MET. ENG., vol. 20, p. 308.

³Bull. Amer. Institute Mining Engineers, 1917, pp. 209-228; CHEM. & MET. ENG., vol. 19, p. 457.

2. A considerable saving in coal consumption and boiler capacity can be effected.

3. The commercial results already obtained in connection with potash recovery indicate that blast-furnace gases are capable of providing a profitable source of potash production under normal competitive conditions.

THE INTERNATIONAL POTASH SITUATION

According to the figures supplied to the writer by the British Bureau of Potash Production, the total exports of potash and potash salts from Germany in 1913 were as given in Table I.

TABLE I.

Total exports of potash and potash salts from Germany in 1913 so far as separate figures are available:

	Metric Tons
Potash and wool grease ash.....	16,271
Caustic potash.....	44,112
Chlorate of potash.....	1,114
Sulphate of potash.....	133,358
Phosphate of potash.....	12
Nitrate of potash (saltpetre).....	16,051
Manganate and permanganate of potash.....	1,521
Muriate of potash.....	393,320
Sulphate of potash and magnesia.....	59,207
Potash salts for manurial and other purposes:	
Carnallite containing from 9 to 12 per cent K_2O	520
Grunite salts containing from 12 to 15 per cent K_2O	1,124,816
Salts containing from 15 to 20 per cent K_2O	49,687
Manures containing up to 38 per cent K_2O	460,865
Waste salts (so-called Staffurtt salts) unenumerated.....	40,269

Exports from Germany in 1913 of certain groups of chemicals in which potash salts are included with other salts:

	Metric Tons
Bromide of potassium, sodium, ammonium and iron; bromoform.....	405
Iodide of potassium, sodium and ammonium; iodoform.....	160
Ammonia, potash and soda alum and other similar products.....	24,733
Chromate and bichromate of potassium, oxide and hydroxide of chromium.....	2,627
Water-glass (silicate of potassium and sodium).....	15,543
Pero- and ferriyanide of sodium and potassium.....	2,254
Cyanide of sodium and potassium.....	6,678
Sulphide of potassium and sodium.....	9,226

The value of potash compounds imported into Great Britain from Germany in 1913 is shown in Table II.

TABLE II.

Detailed statement of values of potassium compounds imported into Great Britain from Germany in 1913:

	Value
Bichromate.....	£974
Bromide.....	7,827
Carbonate.....	33,555
Caustic.....	79,551
Chlorate.....	2,101
Cyanide.....	9,763
Iodide.....	10,351
Lyes.....	8,762
Meta bisulphite.....	1,146
Muriate.....	99,951
Oxalate.....	1,743
Permanganate.....	7,451
Phenylglycine.....	38,832

Belgium.....	Only	20,489
France.....	by	57,115
Sweden.....	Value	12,634
Japan.....		30,654

The British Government has already announced its intention to allow the importation during 1919 of about 20,000 tons of Alsatian potash averaging 14 to 20 per cent K_2O . Also a further 50,000 tons of German potash (80 per cent K_2O), which is to be taken in part payment for goods supplied; and it would seem to be the policy of the government not to issue further permits except in so far as domestic supply is insufficient to cover the demand.

According to an interesting article on this subject in the *Chemical Age* (vol. 1, No. 5, 1919), it is claimed that the post-war requirements for potash will be much greater than the pre-war requirements, and that while the former cost of production of 80 per cent potash is assumed to have been approximately £7 per ton, it cannot be expected that a lower price than about £15 to £25 per ton will be the rule for a considerable period of time.

This surmise is based on the assumption that for many years to come the world's requirements of potash will be far greater than can be met by the combined output from the Alsatian and German fields.

Attention is also drawn to the reported occurrence of rich potash deposits in the Italian colony of Erythrea, Abyssinia,* some hundreds of tons of this material with a chloride of potash content of 75 to 95 per cent having been exported during the war period. The extent and uniformity of these deposits, as well as of similar ones in Spain and Sicily, are still matters for investigation.

Of possible interest is the reference in the same article to the extraction of potash from leucite by a new Italian process. Leucite is a double silicate of potash and alumina containing, when pure, about 28 per cent K_2O , but the Italian product generally contains only 8 to 10 per cent. According to the new method the gangue can be separated electromagnetically, thus increasing the K_2O content to 15 per cent.

The writer wishes to express to the officials of the Department of Potash Production, Board of Trade, England, his appreciation of their kindness in favoring him with the major portion of the data outlined above. It would appear that no small amount of the success obtained is due to the energy and enthusiasm shown by them.

Belgian Wage Scale

The past and present labor situation in Belgium, which might serve for comparison with that in the United States, is given in the following news item taken from the *Fortnightly Information Review*, Nov. 1, 1919:

"In general, the present wage scale in Belgium, as compared with June, 1914, shows an increase from 150 to 200 per cent, according to Trade Commissioner Harry T. Collins, Brussels. Blacksmiths, machinists, etc., employed by the community receive 19 to 24c. an hour, which is an increase over 1914 wages of 225 to 285 per cent for an 8-hr. day. Carpenters receive 23c. an hour for a 54-hr. week, which is an increase of 153 per cent over wages in 1914. Mechanics employed in textile factories receive 18 to 22c. an hour, an increase of 261 to 294 per cent over their wages in 1914, with an 8-hr. day."

*J. Soc. Chem. Ind., 1918, 291T.

Treating Antimony Ores*

BY GEORGE P. HULST†

PRIOR to 1914 there was little demand for antimony in this country; its use was limited almost entirely to the manufacture of type and bearing metals. Practically no antimony ore was mined here, the market being supplied principally from China, and the alloy was produced by a direct mixing of lead and antimony. The great world war, with its demand for shrapnel in hitherto undreamed of quantities, precipitated a great boom in the price of antimony. Nominally quoted at 6c. to 7c. in 1914, the price increased by leaps and bounds to 45c. in March, 1916. Under the stimulus of high prices many small mines were opened, for it became profitable to work ores containing as low as 20 per cent antimony. High-grade sulphide ores (stibnite), containing 55 to 60 per cent antimony, were received from Bolivia, China and Alaska. Low-grade sulphide ores, running from 20 to 45 per cent, were produced in Nevada, California, Idaho, Utah and Mexico; much of this ore was fairly rich in silver. The principal oxide ores came from Mexico and Oregon. The following analyses are representative of various types of antimony ore:

	Sb	Pb	Cu	Ag	Au	SiO ₂	Fe	S	CaO	Zn	As
Oxide ore...	35.09					46.02	0.95	0.40	10.98	0.30	0.22
Sulphide ore 35.20						15.12	1.05	19.87		0.40	0.25
Sulphide ore 37.16	11.30	0.10	34.0			7.60	5.00	17.05	7.40	0.36	0.10
Sulphide ore 41.55	18.00	0.20	76.0	0.04		5.60	0.25	18.17	0.85	0.25	0.10

The International Lead Refining Co. fortunately was equipped to handle these ores through residue and blast-furnaces. The charge consisted of a variety of sulphide ores containing Sb 20 to 60 per cent and SiO₂ 6 to 45 per cent, oxide ores containing Sb 20 to 40 per cent and SiO₂ 10 to 45 per cent. Secondary materials, such as battery plates, battery mud, lead oxide, paint, etc., together with refinery skins, softener skins and other refinery by-products, were treated along with the antimony ore to furnish the lead required. All silver-bearing antimony ores were treated in the residue furnace, the sulphur, iron and copper forming matte that carried part of the silver, the balance going into lead bullion. The antimony slag produced was sufficiently low in silver to warrant being smelted in the blast-furnace to antimonial lead.

The blast-furnace equipment consisted of two 5-tuyere, 42-in. round furnaces connected by flue to the bag house. On account of high zinc and arsenic in lead refinery by-products, we ran a slag of the composition SiO₂ 26 per cent, FeO 40 per cent, CaO and ZnO combined 20 to 24 per cent. Net profit rather than metallurgy prompted a slag as low as possible in antimony, even though the lead content was increased. Average analysis of slag for 6 mo. showed Sb 0.66 per cent and Pb 2.36 per cent. Actual blast-furnace loss was 2.4 per cent antimony and 1.503 per cent lead. Due to sulphur and arsenic on the charge, some speiss was produced. The furnace charge varied from 2500 to 3000 lb. Coke ratio was 13 per cent. Blast pressure was maintained at 10 to 12 oz. The two furnaces smelted 60 to 90 tons of lead and antimonial material per day, producing 30 to 35 tons of antimonial lead of the following average analysis: Sb 13.00 per cent, Cu 0.15 per cent, As 0.75 per cent, Pb 86.1 per cent.

Need of Extensive Research in the Petroleum Industry

BY VAN H. MANNING

THE welfare of any industry must be considered in connection with the welfare of the people. Capital and labor cannot disregard the public; that must be represented and considered. A review of the American petroleum industry shows that the industrial development and general prosperity of the United States depend upon an adequate supply of petroleum. It was one of the prime factors in assuring victory for the armies of the Allies, and today our automobiles, trucks, farm tractors and motor boats are dependent on it for power, and few manufacturing industries can exist without it. There are no known commercial substitutes for gasoline or lubricating oils, and, in fact, petroleum in one form or another reaches every household in the civilized world. As to the future, it is certain that the demand for petroleum will increase.

Faced with this growing need for petroleum, we have to consider seriously the means whereby an adequate supply for the future can be obtained. We know that the domestic output does not meet the present consumption, and that the amount of this deficit will probably continue to increase. Of the original available supply underground, it is estimated by the U. S. Geological Survey that we have consumed 40 per cent that is unreplaceable. A diminishing output with increasing consumption will make the United States more dependent on foreign fields.

It is true that there are vast oil reserves in foreign countries, and if these fields could be developed without hindrance, they could, even though consumption continues to increase at the present rate, probably meet the world's demands for the next ten years at least. Prediction beyond the ten-year period is not safe, for too many uncertainties are involved.

In meeting the world's needs, however, the oil from the United States will continue to occupy a less and less dominant position, because within the next two to five years the oil fields of this country will reach their maximum production and from that time on we will face an ever increasing decline.

DOMESTIC OIL FIELDS UNABLE TO MEET PRESENT HOME DEMANDS

We thus see domestic oil fields unable to meet our home demands under present methods of utilization and manufacture. This startling fact cannot be ignored. We must and can obtain a more efficient utilization of petroleum by proper investigative work. Research work and scientific development work should be actively stimulated.

Our efforts should tend toward obtaining perfection in processes, mechanical equipment, and in the proper development of our plants and processes. The day of empirical formulas and rule-of-thumb methods should not be passively allowed to continue. It is only a scientific research and the adoption of methods pointed out by this research in which natural laws form a basis for the quality and value of any product that we can hope to obtain the most valuable products out of petroleum.

Today there are many laboratory processes which have not been developed further simply because of insufficient funds to install them commercially. One object of research would be to test out on a commercial scale

*Read at the Chicago meeting of the American Institute of Mining and Metallurgical Engineers, Sept. 24, 1919.

†Assistant general manager, International Lead Refining Co.

many of the laboratory processes now dormant commercially because of insufficient funds. Another object of research should be to correlate the pertinent facts of all investigative work and start supplemental research at the point where it is needed. This procedure will avoid costly repetition. The result of all past and current work should be properly correlated and brought under one large head, so that the greatest good can be accomplished and duplication minimized.

RESEARCH AND EXCHANGE OF INFORMATION NEEDED

It is the research man who should point out the manufacturing losses, and indicate the necessary investigative work whereby these losses will possibly be reduced or eliminated. These results should not be stored in the records of one company, but should be available to other manufacturers, so that they may profit by the experience and findings of their neighbors. A proper exchange of information must save much costly duplication of work.

The petroleum industry, valued at billions of dollars annually, is essential to national efficiency, and national efficiency can be attained only through scientific research. The necessity of such research is becoming recognized more and more by the large industrial units, some of which spend thousands of dollars annually for scientific investigations. Many petroleum organizations have scientific bureaus, but much of the knowledge these bureaus gain is confined in the archives of the company's laboratory.

The need of research is recognized in many professions, and particularly in medicine. The medical profession is essential to personal health and life, and vast sums of money have been donated to medical research. As a result, typhoid fever, smallpox and many other deadly diseases have been mastered. The money donated to medical research has been refunded many times over through the saving of life and the increase of human efficiency, and intensive research in the petroleum industry would yield results incomparably more valuable than the cost of the work. A fraction of the sums spent in medical research would, if expended in petroleum investigations, bring about improved methods that would vastly increase efficiency in the utilization of each barrel of oil. In 1918 the value of the output of crude oil and refined products in the United States was about \$2,500,000,000. Certainly the petroleum industry can afford to spend more than has heretofore been spent in research to discover new methods and perfecting those in use, for thereby the recovery of oil will be increased and utilization will be far more efficient. In this way the cost to the consumer will be lessened and a rapidly diminishing commodity, one essential to our existence, will be conserved.

SECRETARY LANE QUOTED

In conclusion, I do not believe that this problem could be emphasized any more strongly than has been done in a letter to me from Secretary Lane, of Sept. 24, from which I quote the following paragraphs which have a direct bearing on the above subject:

"It is not an exaggeration to say that millions of dollars must be spent in experiment before we know the many services to which a barrel of oil can be put. There is almost an indefinite opportunity for research work along this line. Petroleum is a challenge to the chemists of the world. And now the world is dependent upon

it as it is upon nothing else excepting coal and iron, and the foodstuffs and textiles. It has jumped to this place of eminence within twenty years and the world is concerned in knowing how large a supply there is and how every drop of it can best be used.

"We are behind the rest of the world in the use of our oil for fuel purposes. We are spendthrifts in this as in other of our natural resources. We can get three times as much energy as we do out of our oil through the use of the Diesel engine, yet we are doing little to promote development of a satisfactory type of stationary Diesel, or marine design. Instead of seeing how many hundred millions of barrels of oil we can produce and use, our efforts should be to see how few millions of barrels will satisfy our needs."

REQUA SEES DAWN OF "REAL PETROLEUM ERA"

The views of Mr. M. L. Requa, in a letter to me of Sept. 25, have such an important bearing on this great topic that I think it well also to add a few pertinent statements from his letter on this subject.

"I am on record in various published addresses as to my attitude concerning the petroleum problem, and I think it unnecessary to repeat those statements. I cannot, however, refrain from pointing out briefly the acute need that I believe exists for constructive and co-operative work of the character that you are proposing. That it has never been done before has been due to two causes: one, the less pressing need, and the other the lack of realization upon the part of the industry of the necessity for co-operative and constructive action.

"Because of the tremendous increase in the consumption of petroleum products, we have confronting us problems that have been of little concern in the past, but will be of very much greater concern in the future. Satisfactory answers cannot be made, except through constructive action upon the part of the industry. There is no alternative, in my judgment.

"We are, in my judgment, just beginning to see the dawn of the 'real petroleum era.' All signs point to a demand for the product in the future that will far exceed anything in the past. I am optimistic enough to believe that the Diesel engine will be perfected, and become of universal application. If so, the day of the steam unit will have passed.

"The extraction from a barrel of oil of all of the component parts, so far as is commercially practicable, and the distribution of those products in channels of trade, in a useful and economical way, rather than their destruction as is now the case, is a matter of highest concern."

Government Assumes Responsibility for Failure of Castor Bean Crop

More than 18,000 Southern farmers are to be reimbursed for losses sustained in efforts to raise castor beans for the Government. The Board of Contract Adjustment of the War Department has ruled that the Government in furnishing seeds, of which a large percentage failed to germinate, had incurred liability and that the case comes within the purview of the informal contract act. The Government undertook the stimulation of castor bean growth early in the war when it appeared that a sufficient amount of castor oil would not be available for use as a lubricant for airplane engines. The seeds were secured in India and proved to be unsuited to climatic and soil conditions in the U. S.

Relationship Between Transverse Rail Fissures, Flakes and Defects in Fusion Welds

A Consideration of These Apparently Diverse Imperfections Indicates the Strong Probability That All Are Due to One Cause: Films of Oxide Between the Metallic Grains—Examination of Defective Rail and Gun Steel Under Strain Would Probably Throw Much Light on This Point

BY S. W. MILLER*

THE subject of transverse fissures in steel rails is one which is of vital interest, not only to the railroads, but to everyone who travels on them. A very great amount of work and time has been spent trying to determine their exact nature, and especially their cause; and a large amount of information has been secured in regard to them by competent observers who have every opportunity for so doing.

At the meeting of the American Institute of Mining Engineers in February last, George F. Comstock presented a paper on this subject, and the Rail Committee of the American Railway Engineering Association has recently reported on the matter, an abstract of its findings appearing in the *Engineering News-Record* of March 27, 1919, p. 610. Mr. Comstock's paper and the report of the Rail Committee contain probably the latest information in regard to transverse fissures.

The difficulty experienced with flaky gun steel has been considerable, at least in America, and a great amount of investigation has been carried on in order to determine the cause and eliminate the trouble. Of course, its prominence has been aggravated by the greatly increased demand for gun forgings during the war. Two papers on the subject were presented at the February meeting of the American Institute of Mining Engineers, which attacked the trouble from different standpoints, and which were thoroughly discussed. In the issue of CHEMICAL & METALLURGICAL ENGINEERING for March 15, 1919, there is a very important article by Dr. Giolitti, the Italian metallurgist. These articles contain probably all of the important information in regard to flaky steel.

It may seem a far cry from the above two subjects to that of fusion welds, but, as the materials in which the two former defects occur are originally steel castings, and as a fusion weld is the same thing except on a smaller scale, it would seem reasonable that the defects in all three cases would be of the same general nature, although likely to be aggravated in the case of welds because of the lesser degree of skill and knowledge possessed by the average operator, and from the fact that but little attention has been given to defects in welds and to the methods of their prevention. The writer presented a paper at the February meeting of the American Institute of Mining Engineers in this connection. Since that time he has made further examination of heat-treated welds, and finds no reason to change his conclusions in the paper.

Furthermore, as bearing on the general subject, attention is called to a paper by J. C. W. Humfrey, on "The Intercrystalline Fracture of Iron and Steel," in

the Carnegie Scholarship Memoirs, Iron and Steel Institute (1912), vol. 4, p. 80, and also to Mr. Humfrey's discussion of the paper by Prof. Zay Jeffries on "The Metallography of Tungsten" in the November *Bulletin* of the American Institute of Mining Engineers.

Short abstracts from all these references are given herewith in order to sustain the position which the writer has taken in regard to these defects, which briefly is that *they all result from the same cause, which he believes to be films of oxide, or other foreign matter, which lie along the grain boundaries and which impair the physical qualities of the metal.* These films may be so thin as to be ultra-microscopic, and yet may have a serious effect.

In Mr. Comstock's paper, the statement is made that there are two schools whose opposing beliefs are: first, that transverse fissures are the result of fatigue and independent of the quality of the metal; second, that the quality of the metal and the mill practice must have something to do with them. Mr. Comstock associates these fissures with high-phosphorus streaks, using 24 rails having them and 12 rails giving good service as a basis, and also concludes that reheating the rail blooms reduces the tendency toward forming transverse fissures. He does not take the position that the fatigue theory is disproved by his investigations, and attempts to reconcile the two opposing theories by showing that both are probably closely connected with the formation of fissures. He also states in closing that his "paper is presented with the idea of throwing a little light in a new direction on the internal conditions that help the beginning of transverse fissures in rails." In other words, Mr. Comstock tries to find the *starting point* of the transverse fissures found in service, and suggests strongly that segregation due to phosphorus is a probable contributing cause.

LATEST INFORMATION ON DEFECTIVE RAILS

The statements of the Rail Committee are well summarized in the *Engineering News-Record* of March 27, 1919, in "Progress in Study of Rail Quality":

First—Mr. Waring's statement that deep etching as carried out by him on rails found with fissures either in service or during test brings out irregular markings associated with the fissures. He also states that a rail that performed well under test, though from the same heat as some of the defective rails, showed none of the markings. His conclusion is: "Since these rails were all from one heat, of a fairly uniform chemical composition, and rolled at the same time, and since they were all subjected to approximately the same amount of service in the track, it would appear as if these defects found in the rail heads are associated in some manner with the process of manufacture." And further: "An examination of all these deep etchings brings out the fact that these small internal transverse ruptures correspond in their location and appearance with

*Proprietor, Rochester Welding Works.

the nuclei of transverse fissures, and it is possible that they may be the original cause of such fissures."

Second—Mr. Young's closely allied statement is that his findings "are conclusive evidence that flaws and cracks exist in new rails which have been subjected to no strains except those developed in the rolling."

Third—Mr. Cushing's report as to the very much better quality of rails from some mills than others, based on the comparison of elastic limits and deflections, and that annealing removes the brittleness and increases the deflection. Dr. Dudley also makes the same statement with regard to annealing.

Fourth—The percentage of transverse fissures in direct rolled rails is ten times that found in rails from reheated blooms. In the latter there was one fissure per 5466 tons, and in the former one fissure per 531 tons.

Fifth—There is a strong belief that small cracks are produced in rail heads during the gagging.

With regard to flaky steel, the paper¹ by Mr. Clayton and his associates suggests seven possible causes, of which they seem to lean strongly toward No. 5, which is "overheating and non-uniformity of heat of ingot preparatory to forging."

The paper² by Mr. Rawdon concludes as follows:

"On the whole, the microscopic appearance of flaky steel leads to the following conclusions regarding the nature and origin of flakes. They originate in the ingot, in which state they have the appearance of inter-

crystalline shrinkage cracks. They occur in the cast metal along with the slag inclusions in the angles between the branches of the tree-like dendritic crystals. They persist throughout the history of the forging into the finished form as discontinuities in the metal, often associated with slag films, which have resulted from the working down of the slag inclusions with which they are associated from the beginning."

The present writer is strongly inclined to believe that the usual cause of flakes is as explained by Mr. Rawdon, but it would seem quite plausible that at times overheating of the ingot, as referred to in the paper by Mr. Clayton, would cause similar defects which would not be removed during subsequent forging. As evidence of this, the statement made by Mr. Humfrey in discussion of Prof. Jeffries' paper, and appearing in his original paper,¹ shows that intercrystalline brittleness can be produced by overheating, and this brittleness again removed by heating in a reducing atmosphere, such as that of hydrogen. Mr. Humfrey's statement referred to is as follows:

We do, however, know of cases in which certain metals, which normally break through the crystals, may be so altered in character as to tend to break around them. Typical examples of this are:

(b) Pure iron which has been annealed at certain temperatures and in certain atmospheres, and slowly cooled through a certain range. In this case there is evidence to indicate that the weakness is due to the formation of an iron-oxide eutectoid.

Mr. Humfrey was unable to find any microscopical evidence of oxide films around the grains even at high power, yet since the heating in a reducing atmosphere caused the rupture to pass through the grains, as in normal steel, he felt that these films must exist.

DR. GIOLITTI'S OPINIONS

Dr. Giolitti's entire article is worthy of the most careful perusal, especially the following statements:

Flakes originate in tender alloy steels as intercrystalline cracks, probably intensified by inclusions and segregations. They can consequently be controlled by careful steel furnace practice, casting, soaking, reheating, forging and heat treating. . . .

Of even greater importance, however, we feel that free iron oxide (scale and rust) be kept at the lowest possible point in the raw materials charged in the furnace. This refers to scale on the surface of the metal (rusty turnings and borings are never used) and free oxide in the puddled iron itself. . . .

Starting from this pure iron, extreme care is used to prevent superficial oxidation during melting by maintaining a reducing flame in the open-hearth furnace at all times. . . .

What I wish to emphasize is that chromium steel, properly made of pure materials in this manner under reducing conditions and containing no oxide, will never develop flakes. When so made you can pour it into an ingot of any cross-section and forge it as you like—either fast or slow, with reheating or without, with great or slight reduction (always providing the work is done within the correct temperature limits and with usual skill) and flakes will not appear. . . .

On the other hand, a bath of metal properly made from correct raw materials will develop woody structure excessively if only a few kilograms of scale are thrown into the furnace even a long time before tapping. Microscopic examination of this defective metal seldom reveals an increased amount of inclusions, still we feel that this "oxidized metal" is flaky by virtue of its content of emulsified iron oxide, or some substance produced thereby which has diffused or broken up beyond the detection of a microscope.

There are many other statements in Dr. Giolitti's article that are equally positive, and which all point to the fact that oxide is responsible for flaky steel.

The examination of welds made by the writer, and which are summarized in his paper already referred to, was made by bending sections of welds about $\frac{1}{8}$ in. wide and $\frac{1}{4}$ in. thick, and examining them at different stages under the microscope. The same method applied to flaky steel showed two things: first, that the first evidence of rupture was at visible defects, such as dots of oxide or manganese sulphide; second, that where these defects did not exist, the first evidence of rupture was in the ferrite around the grain boundaries. As illustrating these points, photographs Nos. 1, 2 and 3 are shown. In none of the pieces from which these photographs were taken was any defect visible at 1200 magnifications that had the appearance of a crack or film of oxide.

RUPTURE IN WELDS DUE TO OXIDE FILMS

Coming now to the matter of welds, in his paper the writer concluded: first, that all metal-electrode arc welds rupture at the grain boundaries; second, that gas welds made with low carbon material, so that no pearlite exists in the weld, rupture through the grains by slipping as in normal steel; third, that where welds are made from welding rods having sufficient carbon, or other elements which preserve pearlite in the weld, the rupture is along the grain boundaries. Since this paper was presented, other conclusions have been reached, which apply to welds which received heat treatments. These conclusions are: first, that neither quenching from temperatures ranging between 1500 and 1800 deg. F. nor annealing within the same range will prevent the intergranular rupture of electric welds; second, that annealing pearlitic gas welds changes the path of rupture from intergranular to intragranular along the slip planes. The heat treatments referred to were done in an ordinary small electric furnace, no attempt being made to keep the atmosphere reducing. In many instances, a careful examination was made at 1200 magnifications of the polished and etched surfaces of the test pieces before bending in order to locate if possible any defects in the way of oxide films that might exist, but in all such cases, even where there were no visible defects, the paths of rupture were in accordance with the above conclusions. A few of the photographs showing these ruptures are reproduced in connection with this discussion.

It is well known that Armco iron is practically pure iron, the total impurities being less than 0.1 per cent. It has one peculiarity, as have all other materials of the same composition, which is its brittleness when heated to about 1700 deg. F. The writer made some attempts to determine the reason for this brittleness by heating pieces of it to different temperatures for different lengths of time, and finds the results shown in the photographs. Normal Armco iron when under strain develops slip bands, and the grain boundaries remain intact as in Fig. 14. When heated to 1700 deg. F. for ten minutes and quenched in ice water, the grain boundaries appear to be thickened, although it is difficult to judge this positively, the number of slip bands developed is much less than with normal material, and the giving at the grain boundaries is quite frequent. (See Fig. 15.) When heated to 1700 deg. F. and cooled

¹J. C. W. Humfrey: "The Intercrystalline Fracture of Iron and Steel," Carnegie Scholarship Memoirs, Iron and Steel Inst. (1912), vol. 4, pp. 80-105.

slowly to 1600 deg. F. and quenched in ice water, there appear to be films around the grains as shown in Fig. 16. Under strain the ruptures were clearly intergranular, as shown in Fig. 17. Another test that was made was to heat a piece, $\frac{3}{8}$ -in. x 2-in., with an oxy-acetylene torch to about 1700 deg. F. and then to strike the piece while red hot on the end of an anvil. The heated section broke off short when struck, and the piece was caught in a tank of ice water. In a section prepared for the microscope, for a short distance back of the fracture the piece was seamed with grain boundary cracks in which in the unetched section material re-

sembling oxide could be easily seen at high power. Etching the section showed that these defects were at the grain boundaries as in Fig. 18.

These tests appear to show quite clearly that it is possible to produce in the normal iron a condition which is abnormal, and it appears that this condition is due to films around the grains. A similar condition is well known to exist in tool steel, and enough overheating does produce what is commonly called burnt steel. The cause of these films is not known, but the writer offers the theory that they are ultra-microscopic in many cases, and possibly of iron sulphide, due to the small

amount of manganese in the iron. The large rupture in Fig. 18 is probably due to the forcing open of the grain boundaries by the strain and the admission of air, which causes oxide to form.

CONCLUSIONS

Considering all the facts above presented, it seems to the writer quite clear that the following conclusions are justified:

First—That nothing in the evidence so far presented is inconsistent with the theory that transverse fissures, flakes and intergranular ruptures in welds are due to the same cause, that is, films, possibly ultra-microscopic, of oxide; also that it is the only theory that appears to fit all the facts.

Second—That these films of oxide may be present in the ingot and usually are.

Third—That these films of oxide may be caused by overheating of the metal at some stage of the process of manufacture.

Fourth—That if they are caused by the presence of oxide of iron in small amounts only, such as probably causes woody steel, they can be removed by proper heat treatments, such as are stated by Dr. Giolitti and Mr. Humfrey; but if they are caused by larger amounts of oxide of iron, which would form considerable quantities of oxide film, then such heat treatment will probably not remove them.

Fifth—That it appears probable that better mill practice will result in the elimination of flakes and also of transverse fissures.

Sixth—The writer knows that such defects in welds as are visible under the microscope can be entirely eliminated by proper welding methods, which involve nothing but thorough fusion and floating all the oxide and dirt, which is clearly visible during the welding operation, to the surface. In electric welds, this procedure is more difficult because the metal is being constantly added from the electrode, and, in addition to this, the oxidizing conditions are exceedingly severe, as the metal passes through the air in the form of vapor and must become seriously oxidized. It is quite possible that ultra-microscopic films in welds may be removed by heating in a reducing atmosphere.

Seventh—The writer would suggest the examination of rails known to contain transverse fissures that have been in service by polishing and etching small sections and bending them under the microscope. He feels that such an examination would throw some additional light on the matter. He would also suggest that the same tests be applied to sound rails, to rails that show little elongation under the usual tests, to gun forgings and to other samples of steel that do not meet specifications, especially those giving low elongation. It is the writer's experience that welds properly made with good materials will, in a test piece $\frac{1}{2}$ in. thick, give from 22 to 30 per cent elongation in the weld; while welds containing oxide films, though invisible, will give an elongation of from 2 to 10 per cent. The same low elongation appears to be characteristic of flaky steel and defective rail material.

Rochester, N. Y.

[EDITOR'S NOTE.—In fairness to Mr. Miller, we wish to point out that his conclusions and those set forth in CHEMICAL & METALLURGICAL ENGINEERING, Aug. 1, 1919, p. 145, were arrived at by each writer in an entirely independent manner, and in fact Mr. Miller's manuscript antedates the one published Aug. 1.]

Wood Alcohol—Co-operative Caution

BY CHARLES BASKERVILLE

Chairman, Committee on Occupational Diseases, American Chemical Society

UNSCRUPULOUS persons have been selling mixtures containing wood alcohol, as such, or ethyl alcohol denatured with wood alcohol, as beverages. Co-operation of the chemical profession is sought to minimize this infraction of the law.

During the penumbra of prohibition the word alcohol has exercised a weird and unfortunate influence, oftentimes through failure to appreciate the significance of such qualifying words as "wood," "methyl," and "denatured." Numerous cases of blindness and even death have resulted through ignorance or the infamy referred to. The Commissioner of Internal Revenue has as a result issued the following notice:

To the Collectors of Internal Revenue and Revenue Agents in Charge:

T. D. 2014, issued today and showing additional matter to be affixed to containers of completely denatured alcohol, is called to your especial attention.

Reports recently received in the Bureau establish that completely denatured alcohol is being used extensively for bathing and rubbing purposes. This is contrary to the law and regulations, and such uses cannot be tolerated, as the completely denatured alcohol is highly injurious to the skin and animal tissue.

It is also established that completely denatured alcohol is being sold by irresponsible dealers under circumstances as to assure them that it is being used for beverage purposes. Where it is so used for any length of time blindness inevitably ensues, and the continued use can only result in death.

Collectors should use every means at their disposal to make known to the public the dangers of either external or internal uses of completely denatured alcohol. Wherever collectors or revenue agents in charge hear of a misuse of completely denatured alcohol, a most thorough and careful examination should be made immediately and all the facts fully reported to the Commissioner for the infliction upon the responsible parties of the ultimate penalties provided by law.

In view of the grave and extended abuses of the use of completely denatured alcohol reported, it is deemed necessary to print upon the labels affixed to wholesale and retail packages a further and more specific warning as to its use than is shown on the present required label.

In addition to the present matter on the labels there will be required on all new labels hereafter the printing, in large letters in red ink, under the skull and bones symbol, the word poison, and at the bottom of the label there will be printed the following statement:

"Completely denatured alcohol is a violent poison. It cannot be applied externally to human or animal tissue without seriously injurious results. It cannot be taken internally without inducing blindness and general physical decay, ultimately resulting in death."

Until the present stocks of labels are exhausted, this additional matter may be affixed to the containers on a separate label pasted above the present required label.

We chemists know that we daily handle poisons of various kinds, many far more dangerous than wood alcohol, and there are comparatively few evil results from their handling and use. People do not drink them. The medical profession administers daily to patients many substances that are poisons except in the minute doses given. But in the case of alcohol, the "kicker," in drinks of quondam familiar kinds, means just that one desired fluid, hence attendant danger. We should do all in our power to protect those who use and some likely to abuse this important chemical and thus incidentally avoid lurid appeals with consequent hampering legislation.

An Improved Orsat Apparatus for Gas Analysis*

BY G. W. JONES† AND F. R. NEUMEISTER‡

IN RESPONSE to many queries regarding apparatus used at the present time by the Bureau of Mines for general gas analysis, this article is being published with the hope that some of the difficulties now being encountered by those who have had occasion to do gas analysis may be overcome. The authors do not claim

*Published by permission of the Director of the Bureau of Mines.

†Assistant physical chemist, Bureau of Mines.

‡Junior chemist, Bureau of Mines.

originality for the apparatus described other than the few refinements indicated. The apparatus originally designed by Orsat was modified by Burrell and Oberfell,¹ using Jager's copper oxide method for removing hydrogen and carbon monoxide. In this paper especial emphasis is laid on the general plan of wiring, the supports for raising and lowering the burette leveling bulb and adjustment of same, the adjustable brackets for supporting the pipettes and the method of illumination to aid in bringing the reagents to the marks.

It is assumed that the reader is familiar with the general procedure of gas analysis; therefore this part will be described but briefly. The sample of gas is drawn into the burette *c* by turning cocks *d* and *e* to connect with *f*, the point where the sample communicates with the apparatus. Stopcock *d* is then turned to connect with the compensator of Peterssen type, modified by Gregg², as shown in the drawing, Fig. 1. By raising or lowering the leveling bulb the mercury in the compensator makes contact with the platinum wire and lights the lamp *L*. The volume of gas is then read, *d* and *e* are turned to connect with the Orsat apparatus, and the carbon dioxide, unsaturated hydrocarbons and oxygen are removed successively by passing the gas into the pipettes *k*, *l* and *m*, respec-

²Gregg, E. T., "An Improved Compensator for Gas Analysis"; *J. Ind. Eng. Chem.*, vol. 9, 1918, p. 528.

FIG. 1. GENERAL ELEVATION OF IMPROVED ORSAT APPARATUS

tively containing potassium hydroxide solution, fuming sulphuric acid and sodium pyrogallate solution. The contraction is read after passing into each reagent, by the usual method of compensation.

At the beginning of the analysis electrical connections to the heater are closed and all series resistance cut out so as to raise the temperature quickly to the desired point. The heater will reach 300 deg. C. in about the time it takes to reach the point in the analysis where hydrogen and carbon monoxide are removed. The heater is next lowered over the copper oxide tube and rests on the supports *M, M'*. The gas is passed slowly from the burette through the copper oxide tube and down into the combustion pipette *n* by way of the stopcocks *h, h', and g*. The flow of gas is regulated by a pinch clamp to a rate of about 10 cc. per min. Three passes each way are usually sufficient. The heater is then raised and the copper oxide tube is cooled by a compressed air blast to room temperature. The mercury in *n* is brought up to the mark *Q* and the contraction read. This contraction equals the hydrogen in the sample.

Then the gas is passed into the potassium hydroxide solution in pipette *k* several times and once through the copper oxide tube to sweep out the remaining carbon dioxide. This resulting contraction equals carbon monoxide.

The residual gas is then stored in the potassium hydroxide pipette *k* and a definite volume of oxygen drawn into the burette and measured, the amount depending upon the gas being analyzed. Should this be a natural gas, and 30 cc. of residual gas be present, about 100 cc. of oxygen will be necessary. After having measured the oxygen, it is passed through the copper oxide tube and thence into the combustion pipette *n* and stored at atmospheric pressure by adjusting the leveling bulb *O*. Stopcock *g* is now closed and the gas in the potassium hydroxide solution is drawn back into the burette *C*. The platinum wire in *n* is connected electrically through the transformer and the nichrome resistance wire *DD'*, as will be

FIG. 3. ASSEMBLED GAS ANALYSIS SET

more fully explained later, and raised to a desired temperature by means of the sliding contact *H*. The flow of gas is regulated by a pinch clamp and is fed in very slowly to prevent explosions. It is passed directly into the combustion pipette without going through the copper oxide tube. A cooling blast of compressed air is played upon the pipette to prevent breaking. After the gas is completely burned, the electric current is broken and pipette *n* cooled to room temperature, the gas is drawn back into the burette *c* and read, then passed into the potassium hydroxide solution and read again, then burned a second time to insure complete combustion, measured, and passed into the potassium hydroxide again and read. From the figures for total contraction and carbon dioxide produced, the two predominating hydrocarbons present can be calculated by the usual formulas. Nitrogen is always determined by difference.

This is the general procedure for analyzing gases containing carbon dioxide, unsaturated hydrocarbons, oxygen, nitrogen, carbon monoxide, hydrogen, methane and ethane, or for gases containing part of the above constituents as natural gases.

ELECTRICAL CONNECTIONS

The source of current used is 110 volts a.c. A toy transformer and a lever type resistance box are both mounted as a unit as shown in the wiring diagram, Fig. 2. Current from the mains enters the binding posts 7, 6, thence to the switch marked *D.P.S.T.* Here the current branches, part going to a toy transformer of 150-watt capacity and having a variable

FIG. 2. WIRING DIAGRAM

voltage, ranging from 2 to 30 volts. Current from this transformer furnishes light for the compensator, heat for the platinum wire in pipette *n* and light for the illuminator *K*. This illuminator consists of the ordinary 6-volt light connected in series with the toy transformer, and is centrally located in the rear of the pipettes. The current leaves the transformer at 5, *R*, thence to binding posts *A A'* at the base of the apparatus and from here to the single pole double throw switches *I* and *J*, mounted on the base of the Orsat frame in Fig. 3.

When the switch *I* is thrown to the rear the illuminator *K* is lighted. When thrown forward, connection is made with the platinum wire in the combustion pipette. A rough adjustment of the temperature of the wire is made by the sliding contact on the transformer and the final adjustment by sliding contact *H* along the No. 22 nichrome wire held by binding posts *D, D'*. By this method platinum wires of any diameter or length can be used in the combustion pipette without much trouble of readjustment.

When switch *J* is thrown forward, connection is

FIG. 4. ADJUSTABLE MERCURY BULB SUPPORT

made with the compensator *L*, and when to the rear, with the heater for the copper oxide tube. In this manner the switches are easily accessible by the analyst and low voltage current is used for all but the heater.

The copper oxide tube heater, using 110 a.c., is made by taking 40 ft. of No. 22 nichrome wire and winding in the form of a helix. This in turn is wound over a collapsible wooden mandrel protected by a layer of asbestos paper. After the helix of nichrome wire is evenly adjusted over the mandrel, a mixture of calcined magnesium oxide and sodium silicate is made into a thick paste. Thorough mixing in a mortar and using well-calcined magnesium oxide is very necessary; otherwise the furnace will crumble after being in use for a short time. This paste is worked in very carefully between the coils of wire, then wound with a layer of asbestos rope, more paste, asbestos rope and so on until the walls are at least $\frac{1}{2}$ in. thick. The heater is then covered with asbestos paper, the ends protected with "transite" boards and the terminals of the coils drawn out through the asbestos paper and "transite" board and fastened with binding posts. The

furnace is then dried for several hours at 100 deg. C., after which it is ready for use.

PIPETTE SUPPORTS

All the pipettes are supported by adjustable brackets *p*, so that pipettes of any length can be used, or easily removed for cleaning or renewal of reagents.

Fig. 4 shows a device for raising and lowering the mercury bulb connected with the gas burette. By exerting pressure on the lever *A* with the hand, the friction pin *B* is released from the rod supporting the bulb, when the support can be raised or lowered at will. When the pressure is removed spring *C* forces the friction pin *B* into contact with the supporting rod and holds the bulb firmly at that elevation. Final adjustment is made by turning setscrew *D* with the thumb and forefinger, thus raising and lowering the bulb only a very small distance. In making an analysis the solution in the pipette is brought approximately to the correct point when the bulb is clamped and the solution brought exactly to the mark by final adjustment with the setscrew *D*.

It has been suggested that quartz should be used for the copper oxide tube and combustion pipette. The Bureau has had copper oxide tubes and combustion pipettes made of pyrex glass in steady use for over two years without breaking. It is understood that when burning the gas must be fed into the oxygen instead of the oxygen into the gas, also that the pipette must be kept cool by compressed air or by some other means, when burning gases containing a large amount of combustibles—especially those of high molecular weight like ethane and propane.

Copper oxide is hygroscopic, and when an apparatus has not been used for some time it is necessary to give the tube a preliminary treatment by passing air through it for some time at a low temperature in order to drive out the moisture. When the copper oxide has become somewhat reduced, which is indicated by the red color, compressed air or oxygen is passed over the mass heated to a temperature of about 250 deg. C. to revive it.

Bureau of Mines,
Pittsburgh, Pa.

Improvement in Sheet-Ground Region

A marked revival in zinc production in the environs of Miami, Oklahoma, has occurred since the low-price level attained in July, when only about 85 properties were able to produce at the then ruling price of about \$35. Perhaps half as many mills have resumed, in response to an increase in price of zinc concentrates to \$55, which is regarded as being about as much as the present spelter market can carry. Shortage of labor and prospecting rig helpers has prevented a large expansion in tonnage, however, many men having gone into the harvest fields or the Texas oil regions. While a good shoveler working "by the can" earns \$1 an hour, mill men and mechanics have not enjoyed a correspondingly fancy rate. The operators feel that lower costs of living are necessary in order that their employees may be satisfied and labor stabilized, and a fuller resumption of business activities in the United States before the lead and zinc industry, either in the production of mineral or the manufacture of metal, can assume a healthy and profitable condition.

Radiant Resistor Furnace*

The Author Describes His Radiant Resistor Furnace for the Distillation of Low-Grade or Scrap Zinc—
Best Results Obtained With a Current of Approximately 845 Amp. at 65 Volts or 55 Kw.—
With This Power the Output Was About 50 Kg. Refined Zinc Per Hour

By F. A. J. FITZGERALD†

IN 1905 a small laboratory furnace in which the charge was heated by means of radiant resistor was described.¹ A note about a furnace heated in a similar manner, but having an electrical capacity of 150 kw. was published in 1910,² and the description of another design appeared under the title of "A New Electric Resistance Furnace," in a paper given to the American Electrochemical Society in 1911.³ This also had a capacity of 150 kw., and, like the furnace described in 1910, was designed by Thomson and FitzGerald, the object in each case being the smelting of zinc ores by the Imbert process. The furnace described in 1911 was used in experimental work and was found to be very unsatisfactory, as shown in a paper, "Note on an Unsuccessful Furnace Experiment," presented to the American Electrochemical Society in 1911,⁴ but the experiments showed very clearly that the trouble was due to faulty design and construction, more particularly very imperfect heat regulation.

In 1915 the cost of high-grade zinc increased so much that experiments on the distillation of low-grade or scrap zinc appeared to be worth while, therefore Thomson, with our collaboration, designed a furnace on principles similar to those mentioned above, and this was built and operated at the FitzGerald Laboratories, several tons of refined zinc being produced.

The diagrams of Figs. 1, 2 and 3 show the construction of the furnace; Fig. 1 with the cover removed, Fig. 2 a longitudinal vertical section, and Fig. 3 a transverse vertical section. The furnace was approximately 2 meters long (6½ ft.) and the diagrams are drawn approximately to scale. The same lettering is used in all figures.

The parts of the furnace constructed of firebrick are marked *D*, and the heat insulation, which consisted of either Sil-O-Cel or the insulating brick made by the Armstrong Cork Co., is marked *A*. The furnace hearth containing the charge was made of various materials, *L*, but the most satisfactory was a carbonaceous refractory called "Vitricarbo" manufactured by the National Carbon Co. The furnace was heated by two resistors, *R*, which were made from graphite slabs which had slots cut into them so as greatly to increase the path of the current. The current is brought to the resistors by the graphite terminals *T T* and the resistors are connected in series by the graphite connector *T'*. The furnace was charged with molten zinc by means of the inclined tube *S*, the lower end of which was normally below the surface of the molten bath. Above the resistor were two diaphragms *B*. The lower one of these

consisted of a set of plates laid transversely in the furnaces, each plate being one inch distant from its neighbors, thus forming a porous diaphragm. The upper diaphragm was made of 2-in. (5-cm.) carbon slabs, and it did not extend to the ends of the furnace. Thus the zinc vapors had to pass up first through the openings in the lower diaphragm and thence flowed out round the ends of the upper diaphragm, finally reaching the opening *F*, which led to the condenser. The cover of the furnace was formed of carbon slabs *C*, on top of which were the firebrick *D* and finally the heat insulating brick *A*. At *O* there was a hole in the cover into which a pyrometer tube was inserted for measuring the temperature of the zinc vapors passing into the con-

FIG. 1. FURNACE WITH COVER REMOVED

denser through *F*. The condenser is not shown in the diagram, but was in the form of a flat box about 100 x 50 x 7 cm. with a series of transverse baffle plates. This was provided with means for preheating, at first electrically but subsequently with a charcoal fire, since once distillation was fairly under way external heating was unnecessary.

The furnace was originally designed with the idea that it would use 75 kw. or 1000 amp. at 75 volts, and turn out 45 kg. of zinc per hour. It was found, however, that the best results were obtained with a current of approximately 845 amp. at 65 volts or 55 kw., and that with this power the output of distilled zinc was about 50 kg. per hour.

From previous experimental work with zinc furnaces much experience had been gained in the problem of condensing zinc vapor, so that no difficulty was found in

*Paper read at the meeting of the American Electrochemical Society in Chicago, Sept. 23-26, 1919.

†Electric furnace expert, Niagara Falls, N. Y.

²MET & CHEM. ENG., vol. 8, p. 317.

³Transactions (1911) vol. 19, p. 273, et seq.

⁴Transactions (1911) vol. 20, p. 281, et seq.

designing a condenser which would give liquid zinc without the production of any blue powder. There were plenty of other troubles with the condensers, mainly due to the difficulty of constructing the particular form used in such a way that it would not develop leaks. These difficulties were, however, overcome.

The method of working the furnace was as follows: When building it, before putting in the resistors, as much scrap or low-grade zinc was put into the hearth *L* as it could contain, and the construction of the furnace then finished. After starting, the current was at first kept very small so as to dry out the furnace

FIG. 2. LONGITUDINAL VERTICAL SECTION OF FURNACE

slowly, then it was raised and more zinc from the premelter introduced through *S* until the lower end of *S* was well closed. Meanwhile the condenser was heated to a temperature slightly above the melting point of zinc. When the zinc vapor began distilling, the temperature in the condenser rose till finally it was no longer necessary to supply external heat, but instead some of the heat insulation was removed. Thereafter it was merely necessary to keep a watch on the condenser temperature and slightly adjust the air-cooling devices. The zinc was tapped from the condenser at intervals, and premelted zinc introduced so as to keep

FIG. 3. TRANSVERSE VERTICAL SECTION OF FURNACE

the lower end of the tube *S* closed. From time to time the residue in the furnace, consisting mainly of zinc very high in iron and lead, was tapped from the furnace at *P*.

One interesting accident which happened once or twice was the plugging up of the charging tube *S* caused by pouring in molten zinc too near its freezing point. This was cleared by making electrical contact with the bath through the tap hole at *P* and then arcing on the frozen zinc with a rod introduced through *S*.

The experimental work on the distillation of zinc ran over many months, for all sorts of investigations were made on forms of resistors, designs of terminals, various kinds of premelting furnaces, small-scale experiments on fractional distillation of zinc alloys, production of blue powder, various forms of condensers, refractory materials, heat insulators, etc. But to give an idea of the furnace's working under normal conditions, a run of 37 hours may be taken, because this will show the behavior of the furnace after starting up and also what may be expected from it with continuous running under constant conditions. Energy measurements were made at the furnace. The zinc charged into it was in the molten state, hence the figures for energy consumption do not include melting. Here are the data obtained:

Length of run.....	37 hr.
Average power used during distillation.....	55.2 kw.
Total energy for distillation.....	2051 kw.-hr.
Minimum temperature of zinc entering condenser.....	1040 deg. C.
Average temperature of zinc entering condenser.....	1225 deg. C.
Average temperature of zinc in premelter.....	550 deg. C.
Weight of zinc condensed.....	1558 kg. (3494 lb.)
Weight of zinc condensed per hr.....	43 kg. (95 lb.)
Energy per kg. of zinc.....	1.29 kw.-hr.
Energy per lb. of zinc.....	0.59 kw.-hr.

In order to get a notion of the behavior of the furnace when it has reached normal working conditions the last 9 hr. of the run may be taken:

FIG. 4. COOLING CURVE OF THE FURNACE

Length of period.....	8.9 hr.
Average power used during distillation.....	54.4 kw.
Total energy for distillation.....	484 kw.-hr.
Av. temperature of zinc vapor entering condenser.....	1250 deg. C.
Average temperature of zinc in premelter.....	550 deg. C.
Weight of zinc condensed.....	455 kg. (1001 lb.)
Weight of zinc condensed per hr.....	51 kg. (112 lb.)
Energy per kg. of zinc.....	1.06 kw.-hr.
Energy per lb. of zinc.....	0.48 kw.-hr.

A question that will naturally be asked is how much energy was used in premelting the zinc fed into the furnace. Unfortunately the records do not give a direct answer to this question, for much trouble was experienced with the premelter during the earlier part of the run. However, it is possible to get a fairly close approximation of what energy we used for premelting during the last 9 hr. of the run from the following data:

Substitute Metals in Electrotechnical Industries in Germany*

THE most important of these substitutions is the use of aluminum in manufactures formerly made of copper. Before the war it was almost universal practice in Germany to use exclusively copper for bodies which had to conduct electric current. Germany used before the war about 200,000 tons of copper per year, not including copper exported in finished articles. Of this quantity, scarcely 10 per cent was furnished by her own mines.

At the beginning of the war very great quantities of copper were used for munitions, submarine boat motors, and other important war material; at the end of 1914 the necessity of substitutes for the fast-vanishing supply of copper was clearly seen. The principal substitutes are iron, zinc and aluminum, all of which have lower electrical conductivity than copper; therefore, to avoid great losses of electric energy, larger cross-sections must be used, entailing greater cost of metal and of construction to support it.

The accompanying diagram gives at a glance the relative values and usefulness of copper, aluminum, zinc and iron as electrical conductors. Line I shows the relative electrical conductivity of the four metals. Line II shows the specific gravities. Line III shows the relative weights of metal necessary to use for a conductor of a given length in order to get equal current carrying power (conductance); these ordinates are made proportional to I divided by II. If the points on line III are multiplied by the price of the metal per kilo, line IV results, which shows the relative costs of lines of equal length and the same conductance, at present prices for plain wire or rod metal. It is seen that aluminum needs to be only about one-half the weight of copper, and costs, at present prices, about four-fifths as much. These relations will change with the market prices. While the conductivity is one of the most important characteristics to be considered in this comparison, it is not the only one which influences the use of these metals for electrical conductors.

Iron has the advantage of great mechanical strength, which gives it many advantages for suspended freely-hanging conductors. Its conductivity is so small, however, that its strength can be of importance only where electrical energy losses are of secondary importance. A still more important question is the magnetic qualities of iron, which frequently forbid its employment in machines, and cause too great losses by the energy consumed in magnetizing and de-magnetizing it, where alternating current or pulsating direct current is used. Iron was therefore used during the war in a very few places for conducting the current, such as in relatively short high-tension lines, in some special switches for small amperage, and for collector brushes on small direct-current machines. In the future almost all these will be replaced by copper or aluminum, with perhaps the possible exception of the above-mentioned short high-tension lines as long as these are used as branch lines to separate consumers and are not in the circuit of the principal line.

Zinc was much spoken of as a substitute metal in the early days of the war. It has very little mechanical strength, and therefore is unsuited for freely-suspended conductors or similar purposes. Zinc wire insulated with rubber and cotton was quickly put to use as installed conductors in buildings, for light and power purposes. Attempts were made to alloy it, in order to increase its mechanical strength, but it was found that only the purest zinc would stand the requirements necessary for installing such wire in buildings. After overcoming these difficulties, many thousand kilometers of such wire was laid, without any difficulties arising which could be ascribed to the zinc. In such use it must be observed that the zinc is not installed at low temperatures, say under 5 deg. C. (40 deg. F.), that it will not stand high temperatures, such as 80 to 100 deg. C. (176-212 deg. F.), and must not be subjected to any continuous vibration. Under such adverse conditions it becomes brittle, crystallizes and forms a discontinuous mass which cannot carry the current. At first zinc was also used for windings of dynamos, transformers, coils for various apparatus, etc., and apparently with success, but difficulties arose

RELATIVE VALUES AND USEFULNESS OF COPPER, ALUMINUM, ZINC AND IRON AS ELECTRICAL CONDUCTORS

I. Relative electrical conductivity. II. Specific gravities. III. Conductance. IV. Product of conductance and price of metal per kilogram.

so frequently, because of the above-noted properties, that even during the course of the war such applications were given up. On a large scale, zinc is now used only in insulated installed wiring, but even this use will probably be abandoned to copper or aluminum.

Aluminum is the metal which has mostly replaced copper during the war, and which will stand alongside of copper in the future. In this replacement, however, other questions than the specific properties of aluminum must be considered. At the beginning of the war there was no aluminum works in Germany and only imported aluminum ingots were available. This crude metal came from Switzerland, which in turn obtained the aluminum oxide or alumina, from which the metal is extracted, from France. During the first part of the war the Germans were able to obtain all the aluminum required, but later the supply diminished so that they felt the necessity of

*Abstracted from *Das Technische Blatt*, May 3, 1919, p. 24. A. Peckinhaus, "Ersatzstoffe in der Elektrotechnischen Industrie."

building their own reduction plants. This became the more practicable since meanwhile alumina was being manufactured in Austria, Galicia and even in Germany, thus providing the raw material for the industry. The cost of production was immaterial, since the metal had to be made as a war necessity. Switzerland, with its cheap water power, could naturally produce cheaper, but the large amount of power necessary had to be found in Germany. The plants were therefore placed near the fields of brown coal (lignite), which is a relatively cheap fuel, useful alike for manufacturing alumina from the raw minerals and for raising steam to provide the power necessary for the electrical reduction of the alumina to metal. Today the German output of aluminum is already important, although the works are not yet all completed. It is naturally of the greatest importance for Germany to reduce as far as possible its need of importing copper, and to produce its substitute, aluminum, from German raw materials in German factories. It is estimated that it will be possible for them thus to shut off permanently one-third of the former importations of copper, corresponding to a value of several hundred million marks yearly. But since enormous stocks of copper have accumulated in America, which after the war will be dumped on the German market at low prices, it will be necessary that their domestic aluminum works be able to compete with cheap American copper.

Although aluminum has only one-third to one-fourth the mechanical strength of copper, yet it is strong enough to be used extensively in all kinds of bare conductors. Its use as insulated wire installed in buildings has already been alluded to. It is also used in lead-covered cables which are buried in the ground, particularly for the smaller cross-sections. Three-phase motors and transformers, excepting the quite small types, are exclusively provided with aluminum windings. Direct-current motors have aluminum magnet-windings; it is also used in collectors and a large number of apparatus, instruments and installation equipment.

A difficulty is produced in some places by the layer of oxide which forms on aluminum, a thin film of aluminum, which gives poor contact at the binding posts. It can also not be welded or soldered easily. Special methods are therefore used to make secure and durable contacts or joints, but these are not sufficiently simple to enable aluminum in all cases to replace the much more easily soldered copper. The armature windings of direct-current generators, for instance, have been made of aluminum, but more recently the makers have returned to using copper, since the many connections of the armature coils to the collector sheets give trouble.

NEW RULES FOR THE USE OF METALS

The German Electrotechnical Union has recently set forth new rules concerning the use of copper, aluminum, etc., based on experience collected during the war; these rules must be observed, under penalty. According to these rules, the above-mentioned uses of aluminum are, for the greater part, to be continued, since experience has shown that this can be done without detriment to the quality of the manufactured object. A large part of the purchasers of

It is stronger than stated, up to two-thirds to three-fourths.—Abstractor.

electrical equipment have still a certain mistrust concerning the use of aluminum, for instance in three-phase transformers and motors, and insist on having only copper. For this reason, ten and twenty-year-old machines are being sold at extraordinarily high prices simply and only because they are wound with copper. This fact tends to increase the mistrust of the purchasing public against aluminum, which sentiment is skillfully nurtured by the people having such old machines to sell, in order to obtain still higher prices. But the quality of the machines now being made with aluminum is so high that this prejudice is certain to subside and the general use of aluminum for such purposes may be taken as certain, since it is in reality a complete and satisfactory substitute.

The war has therefore been fruitful to the electro-technical industries of Germany, in that it has taught by sheer necessity how to manufacture as independently as possible of importations from foreign countries, and using only the domestic raw materials. The commercial balance sheet will thus gain a permanent advantage.

The Proposed Belgian Steel Trust

The proposed Belgian steel plant combination is discussed by the *London Iron and Coal Trades Review*. The origin of the scheme is attributed to M. Trasenster, general director of the Ougrée-Marihay Co., who recently invited representatives of the works to attend a meeting to consider the scheme. The works represented were the Cockerill Co., Thy-le-Château, Sambre and Moselle, Angleur, Espérance Longdoz, Athus-Grivegnée, Usines Métallurgiques du Hainaut, Monceau Saint-Pierre, Forges de Clabecq, La Providence, Châtelineau and Boel. The meeting is reported to have approved the plan in principle, although two of the most important works are said to have hitherto held aloof.

The proposition is that the combination should take over the assets and liabilities of the constituents, and that the share capital of 300,000 francs be allotted to the works in proportion of the respective values of their undertakings. In order to reach a basis of valuation a meeting of the financial representatives of the works has just been held at the Société Générale, Brussels. After discussion the following points were agreed to as the basis: Ascertainment of the stock exchange value of the shares on June 30, 1914, ascertainment of the profits in the 30 months immediately preceding July 31, 1914, and inventory of the buildings, mine fields, materials, etc. In this connection the representatives of the Ougrée and Providence companies stated that it was impossible at present to ascertain the future value of the iron-ore mines and their investments in mines which they possess in Luxemburg and France, and the Angleur company associated itself with this objection. The three companies, however, eventually agreed that the value of their iron-ore rights should be determined by experts.

The managing director of the Ougrée-Marihay Co. stated recently that, if the amalgamation was carried out, each works would specialize in the product for which it was best adapted and thus be in a position to lower the producing costs and selling prices without lessening the profits.

Recent Chemical and Metallurgical Patents

British Patents

Complete specifications of any British patents may be obtained by remitting 25c. each to the Superintendent of British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Sulphonic Acids.—Sulphonic acids are isolated from crude sulphonation products in the form of salts of divalent or trivalent metals, such as magnesium, aluminum, iron, nickel, cobalt, cadmium, or zinc, by adding to the crude product a soluble sulphate of such metal in amount not exceeding 5 per cent in excess of the theoretical amount for double decomposition, the strength of the sulphuric acid in the mixture being maintained throughout at 30 to 50 per cent; the precipitated salt is filtered and washed with a cold saturated solution of the sulphonic acid salt obtained in the previous operation; part of the filtrate is neutralized with metal, oxide, hydroxide, or carbonate, and used to provide the metallic salt for the next operation, while the rest constitutes recovered sulphuric acid. The process may be applied to the separation of two or more mixed sulphonic acids obtained by sulphonation. Examples are given of the isolation of benzene sulphonic acid as magnesium salt, the separation of phenol-p-sulphonic acid as zinc salt, and the separation of m-xylenesulphonic acid as magnesium salt. (British Patent 14402—1915. A. LAPWORTH and H. N. MORRIS, both in Manchester; May 14, 1919.)

Explosives.—Methods of preparing explosives which consist in the use of dicyandiamidine perchlorate alone or mixed with other ingredients as blasting and military explosives and in methods of manufacturing the dicyandiamidine perchlorate. One example of such explosives contains dicandiamidine perchlorate 69 per cent, sodium nitrate 29 per cent and wood meal 2 per cent. Another example contains dicyandiamidine perchlorate 10 per cent, trinitrotoluene 10 per cent, and ammonium nitrate 80 per cent. One method of manufacturing dicyandiamidine perchlorate is to convert dicyandiamide into dicyandiamidine sulphate, and then add to a solution of this a solution of barium, strontium or calcium perchlorate. Another method of manufacturing is to convert dicyandiamide into dicyandiamidine hydrochloride by heating with hydrochloric acid, and then add a hot concentrated solution of sodium perchlorate; this reaction also takes place at ordinary temperatures. (British Patent 14706—1915. W. RINTOUL, E. G. BECKETT and NOBEL'S EXPLOSIVES CO., Ardeer factory, Stevenston, Ayrshire; May 14, 1919.)

Explosives.—Method of making explosives by adding 82 parts of ammonium perchlorate or $83\frac{1}{2}$ parts of potassium perchlorate to about 18 or 16½ parts respectively of melted paraffine wax. After cooling, the mixture may be pressed into any shape desired or may be used in the form of powder or granules. (British Patent 14932—1915. PERCHLORATE SAFETY EXPLOSIVES, LTD., and H. HARRIS, London; May 14, 1919.)

Explosives.—Method of making explosives by mixing ammonia perchlorate with calcium or barium silicide, to which may be added sodium or potassium nitrate and other ingredients such as paraffine wax, wood meal and aromatic nitrohydrocarbons, for example

trinitrotoluene. An example contains 75 per cent of ammonium perchlorate, 15 per cent of calcium silicide, and 10 per cent of paraffine wax. (British Patent 10865—1915. E. I. PRONK and F. E. W. BOWEN, both in London; May 14, 1919.)

Cracking Hydrocarbons.—High boiling hydrocarbon oils and residues are converted into low boiling hydrocarbon by bringing them in the liquid state into contact with pumice stone or sandstone heated to 500–800 deg. C. in a closed retort, and condensing the resulting vapors. The vapors are removed by a pump and are fractionally condensed under pressure, for example 16 atmospheres. Viscous hydrocarbons, such as tars, are preheated to increase their fluidity. In treating tar for the production of toluol, a temperature of 750 deg. C. is employed. Liquid fuel of the nature of petrol is produced from fuel oil at about 550 deg. C. (British Patent 10981—1915. J. G. ROBERTSON, Partick; and J. NILSON and PETROL PATENTS, LTD., Glasgow; May 14, 1919.)

Ketones.—Acetone and di-ethylketone are prepared by passing the vapor of acetic or propionic acid over manganous oxide at about 350 deg. C. The manganous oxide is distributed or supported so as to present an extended surface and remain porous. This may be effected by boiling pumice in a solution or suspension of manganous acetate or carbonate, drying, and heating until the oxide is formed. (British Patent 14085—1915. N. V. SEDGWICK and B. LAMBERT, both in Oxford; May 14, 1919.)

American Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Basic Sulphate of Zirconium.—It has been proposed to produce zirconium oxide by first preparing a zirconium oxychloride and treating this with a definite amount of sulphuric acid, the mixture being allowed to stand in the cold or at about 40 deg. C., when a basic sulphate of zirconium having the composition $3\text{ZrO}_2 \cdot 2\text{H}_2\text{SO}_4$ separates in small prisms which are free from iron and titanium. This basic sulphate of zirconium can be converted to zirconium oxide by any well-known method. The method is, however, objectionable in that the time required for the precipitation of the basic sulphate of zirconium extends over a great number of days. Further, the precipitation is never complete, less than 75 per cent precipitating out in two weeks. EDWARD J. PUGH of Glenside, Pa., uses the following modified procedure to obtain a better yield in less time: A quantity of zirconium oxychloride containing 100 g. of zirconium oxide is dissolved in 3 liters of water; this solution is acidified with hydrochloric acid and an addition of 48 g. of sulphuric acid is made. So long as the solution remains cold, little or no precipitate is formed, but upon heating a white crystalline precipitate is formed having the composition $5\text{ZrO}_3 \cdot 3\text{SO}_4 \cdot 13\text{H}_2\text{O}$. The zirconium is thus precipitated as a new basic sulphate free from iron, titanium and silicon and capable of ready conversion to pure zirconium oxide in any well-known manner. (1,316,107; assigned to Pennsylvania Salt Mfg. Co.; Sept. 16, 1919.)

Cellulose Solvent.—Cellulose is soluble in mixtures of hydrochloric, sulphuric and phosphoric acids. For example: 1 kg. of air-dried cotton is kneaded with

about 6 kg. of a mixture of hydrochloric acid (35 per cent HCl) 9 parts, sulphuric acid (99 per cent) 0.5 part, and phosphoric acid (85 per cent) 2 parts, all by weight; the solution is cooled to prevent escape of HCl. A thick viscid mass results, which may be clarified and then forced through nozzles into a suitable coagulating bath, as water, dilute acids, solutions of various salts, solutions of colloids and various other media such as alcohol, etc. The solution may also be allowed to hydrolyze and the glucose thus formed may be recovered or fermented to alcohol. (1,315,393; ZENO OSTENBERG of San Jose, Calif.; Sept. 9, 1919.)

Production and Use of Aminocymene as a Dye Intermediate.—The so-called "spruce turpentine," which is a by-product from the relief liquor collected in the process of making sulphite pulp from spruce chips, contains cymene, terpenes, H_2O and dissolved SO_2 . CHESTER E. ANDREWS of Pittsburgh proposes the following process for recovering and utilizing the cymene. Spruce turpentine is treated with sufficient quicklime to combine with and precipitate the H_2O and SO_2 present. After filtering, the liquid contains approximately 75 per cent cymene, the remainder being terpenes. This mixture is dissolved in 98 per cent sulphuric acid and nitrated with mixed acid at 0 deg. C. The product is poured into cold water, the oily layer separated and washed with dilute alkali solution. The principal ingredient is mononitrocymene (1-methyl-2-nitro-4-isopropylbenzene). This is easily reduced to the corresponding amino compound, which may be purified by agitating with dilute sulphuric acid, forming the sulphate of the amine. This is not volatile with steam and may thus be separated from the impurities (terpenes) by steam distillation. The sulphate is then decomposed by alkali and the pure aminocymene recovered by steam distillation. The remainder of this series of patents is devoted to a description of the various dyes which can be obtained from monoaminocymene by the following general reactions: (1) Diazotizing, followed by coupling with hydroxy or amino compounds; (2) Reduction with Zn in alkaline solution to form hydrocymene, which gives, by the benzidine reaction, dimethyl-di-isopropylbenzidine. This may be coupled with a variety of compounds. (3) Monoaminocymene and its derivatives may be mixed with aniline, nitrosophenol, aminophenols, etc., and fused with sulphur to form sulphur dyes. (1,314,920 to 1,314,929 inclusive; assigned to the Selden Co., of Pittsburgh; Sept. 2, 1919.)

Preparation of Pure Ethylene.—Ethylene may be separated from a gaseous mixture (formed, for example, by the process outlined in U.S.P. 1,315,540) by passing the gases through a neutral or acid solution of mercuric salts. In the case of mercuric sulphate, a compound having the empirical formula $HgSO_4 \cdot C_2H_4$ is formed at temperatures between 0 and 25 deg. C. The compound is decomposed on boiling the aqueous solution, yielding pure ethylene. (1,315,541; GEORGE O. CURME, JR. of Pittsburgh, assignor, by mesne assignments, to Union Carbide Co.; Sept. 9, 1919.)

Acetone From Acetic Acid.—Acetone may be prepared from acetic acid in the vapor form by passing the same through tubes or vessels containing iron in a finely divided condition, as of fine shavings, maintaining these tubes or vessels at a temperature be-

tween 550 and 600 deg. C., at which temperature a quantitative yield of acetone is obtained from the acetic acid introduced, condensing the vapors issuing from this apparatus and then preparing from the condensate, by simple rectification, the pure acetone. (1,315,544; GEORGE O. CURME, JR. of Pittsburgh, assignor, by mesne assignments, to Union Carbide Co.; Sept. 9, 1919.)

Ethylene and Propylene Dichlorides.—GEORGE O. CURME, JR. of Pittsburgh claims that chlorination of ethylene and propylene proceeds with greater ease and rapidly in the liquid phase than in the gaseous phase. For example, pure chlorine was liquified in a vessel cooled to -78 deg. C. and gaseous propylene supplied through a tube reaching to the bottom of the vessel. The propylene liquefied before mixing with the chlorine. When the theoretical quantity of propylene had been added, the product was found to consist of 80 to 85 per cent propylene dichloride with 15 to 20 per cent higher chlorinated derivatives. (1,315,542, 1,315,545 and 1,315,547; assigned to Union Carbide Co.; Sept. 9, 1919.)

Personal

MR. JOHN H. ALLISON has joined the sales engineering department of the Celite Products Co., in the Pittsburgh district.

DR. SERGIO BAGNARA is now consulting engineer and general manager of the Marine & Commerce Pocahontas Corp., Welch, W. Va.

MR. H. A. BRAENDLE, formerly of the general laboratories of the Canadian Consolidated Rubber Co., has joined the rubber section of the Ames Holden McCready System, as physicist in charge of its Montreal laboratories.

MR. C. E. CARSTENS of Anaconda, Mont., has accepted a position with the Andes Copper Mining Co., at Potrerillos, Chile.

MR. O. A. P. CLARK of Murray Howe & Co., New York City, has resigned to accept a position as assistant operating chemical engineer with the Newport Co., of Milwaukee, Wis., at its Carrollville works.

MR. WILLIAM M. CORSE has resigned as technical superintendent of the Ohio Brass Co. to accept a position as general manager of the Monel Metal Products Corp. of Bayonne, N. J.

MR. ROBERT S. DAVIS has taken a position with Walker Bros. Consolidated Copper Co., at Portola, Calif.

MR. ROSS H. DICKSON, formerly captain in the Ordnance Department, U. S. A., and engaged on the construction of toluol recovery plants during the war, before which he was with the Smet-Solvay Co., has just been released from the service and is now located with the Standard Oil Co. of New Jersey at the Bayway refinery, Elizabeth, N. J., as chemical engineer in the manufacturing development division.

MR. WALTER DOBBINS, formerly with the Chino Copper Co. at Hurley, N. Mex., has gone to Chuquicamata, Chile, in the employ of the Chile Exploration Co.

MR. D. K. FRENCH, who has served the Chicago section of the American Chemical Society as secretary and treasurer for nine years, on retiring from active participation in the work, was presented with a testimonial subscribed by the members as an appreciation of his long and faithful service.

MR. WALTER H. GARASHIA has severed his connection with the Deegan Supply Co., and associated himself with the Atlas Laboratory Equipment Bureau, Chicago, Ill.

MR. LOUIS J. GREVICH has resigned his position as assistant physicist in metallurgy with the Bureau of Standards and has accepted the position of metallurgist in the research department of the Hydraulic Pressed Steel Co. at Cleveland, Ohio.

Mr. F. D. HARGER has accepted the position of general manager and vice-president of the Mono Corporation of America, Buffalo, N. Y.

Mr. H. H. HARRIS has been appointed manager for the department of heat-treating equipment of the Quigley Furnace Specialties Co., New York. Mr. Harris was formerly general sales manager for the Swedish Crucible Steel Co.

Mr. W. W. HARTMAN has accepted employment with the Eastman Kodak Co. as research chemist on organic chemicals.

Mr. ELLWOOD HENDRICK, consulting editor of *CHEMICAL & METALLURGICAL ENGINEERING*, delivered a lecture under the auspices of the Pittsburgh chapter of Phi Lambda Upsilon at Carnegie Lyceum Hall on the evening of Dec. 3 on "Chemistry for Every Man." At noon of the same day Mr. Hendrick addressed the student body of the University of Pittsburgh.

Mr. J. D. JONES, recently with the Illinois Steel Co., is now general superintendent of the Algoma Steel Corp., at Sault Ste. Marie, Canada.

Mr. LOUIS J. KROM has resigned as managing editor of *Metal Industry* to accept a position as works manager with the new rolling mill of the West Virginia Metal Products Corp. He will continue on the staff of *Metal Industry* as rolling mill editor. Mr. ADOLPH BREGMAN is the new managing editor.

Mr. H. F. MCCONNELL has recently become superintendent in charge of the Louisville plant of the Tobacco By-products and Chemical Corporation.

Mr. L. H. NELSON has resigned his position as research chemist for the Goodrich Rubber Co. at Rock Island, Ill., and taken a position in the laboratory of the Standard Textile Products Co.

Mr. JAMES G. PARMELEE, recently research metallurgist with the School of Mines in co-operation with the U. S. Bureau of Mines, at Moscow, Idaho, is now connected with the Hardinge Conical Mill Co., Salt Lake City, Utah.

Mr. W. L. PENICK, until recently connected with the Salt Lake City office of the Hardinge Conical Mill Co., has been advanced to the position of Northwest sales manager, and will open a new branch office in Spokane, Wash.

Commander DONALD RILEY of the U. S. Naval Reserves has received the Order of the Crown from King Albert of Belgium for his service in that country as chemistry expert.

Mr. H. F. SCHIPPEL, formerly research engineer of the Canadian Consolidated Rubber Co., has joined the rubber section of the Ames Holden McCready System, as research engineer.

Mr. FRANK H. SMITH, until recently general manager of the East Helena plant of the American Smelting & Refining Co. and associated with the company since its organization, has accepted the position of assistant of the Bunker Hill & Sullivan Mining & Concentrating Co., at Kellogg, Idaho.

Mr. R. T. WALKER has resigned as superintendent of the Virginia Louise Mining Co. at Pioche, Nev., to become manager of the Ore Purchasing Department, United States Smelting, Refining & Mining Co., at Salt Lake City, Utah.

Dr. GERALD L. WENDT, of the University of Chicago, recently delivered a talk on "The Revelations of Radium," at the meeting of the Davenport Commercial Club.

Weaver continued as editor until May, 1919. He was intensely interested in the organization of the electrical engineering profession and in the societies through which it was perfected. He served six years as manager of the American Institute of Electrical Engineers and was one of the founders of the Illuminating Engineering Society and the American Electrochemical Society.

Mr. E. C. MCKELVY, chief of the Physical Chemistry Section of the Chemistry Division of the Bureau of Standards, died of burns Nov. 29. The accident which resulted in his death occurred on Friday, Nov. 28, and the burns he sustained were at first considered not grave. Mr. McKelvy was active as secretary of the Washington Chemical Society and was a member of the American Chemical Society, the Washington Academy of Sciences, the American Association for the Advancement of Science and several other technical and scientific organizations.

Current Market Reports

The Non-Ferrous Metal Market

New York, December 22, 1919—Lead and tin have advanced, but copper remains at 28½c. There has also been a general rise in the price of scrap metals.

	Cents per Lb.
Aluminum, 98 to 99 per cent.	32.00-33.00
Antimony, wholesale lots	9.75
Nickel, ordinary	42.00
Nickel, electrolytic	45.00
Tin, Straits, spot	53.50
Lead, New York, spot	7.25
Lead, E. St. Louis, spot	7.00
Zinc, New York	8.57½
Zinc, E. St. Louis	8.22½
Silver	(Cents per oz.) 1.34

FINISHED METAL PRODUCTS

	Warehouse Prices, Cents per Lb.
Copper sheets, hot rolled	28.50
Copper sheets, cold rolled (over 14 oz.)	30.50
Copper bottoms	37.00
Copper rods	29.50
High brass wire and sheets	25.50
High brass rods	24.50
Low brass wire and sheets	28.25
Low brass rods	28.25
Brazed brass tubing	37.25
Brazed bronze tubing	42.00
Seamless copper tubing	32.00
Seamless bronze tubing	36.00
Seamless brass tubing	30.50

SCRAP METALS

	Buying Prices Cents per Lb.
Aluminum castings	22.00-23.50
Aluminum sheets	21.00-22.50
Lead, heavy	5.60-5.85
Lead, tes.	4.38-4.50
Zinc, scrap	4.50
Copper, heavy cut and crucible	15.50
Copper, heavy and wire	13.50
Copper, light and bottoms	12.50
Brass, heavy	8.00
Brass, light	6.15

The Iron and Steel Market

In the steel mills and departments that had been closed by coal shortage there has been a rapid resumption since the Indianapolis settlement of Wednesday, Dec. 10. The following Monday the majority of the closed departments opened, although it was only on that day that coal production on any large scale was beginning at the union mines. The quick resumption was due chiefly to the prompt release of coal which the railroads, under direction of the Fuel Administration, had been holding in reserve to be parceled out for the most essential uses. An estimate that seems fair is that of the total amount of consigned coal held by the railroads on Nov. 1, when the coal strike started, about one-third remained at the time of the Indianapolis settlement. Much of this coal lay near, but not in, the original consignee's works, and the release of the coal meant immediate delivery. The total curtailment in steel production due to coal shortage was an important item on the basis of a week's production, but a small item in comparison with a month's normal output, and an insignificant amount in a year's total.

BLAST-FURNACES DECREASE PRODUCTION

The blast-furnaces have not been having as easy a time as the steel mills. The by-product coke ovens have been

Obituary

WILLIAM DIXON WEAVER, former editor of the *Electrical World*, died at his home in Charlottesville, Va., on Nov. 1, death coming apparently from heart failure while he slept. Mr. Weaver was born in Greensburg, Pa., Aug. 30, 1857, and after completing his studies at Kentucky University entered the United States Naval Academy, from which he was graduated in the class of 1880 as cadet engineer. The next twelve years were spent in the Navy. In 1893 Mr. Weaver was made editor of the *Electrical World*, then published by the W. J. Johnston Co. This journal was later purchased by Mr. McGraw and consolidated with the *American Electrician* and the *Electrical Engineer*. Mr.

increasing their operations but are not yet running full and may not until after Christmas. As to the Connells-ville region, its production of coke was to be restricted by 25 per cent according to the original order, but by 50 per cent according to the final order, this order being rescinded Saturday morning, Dec. 13. In the week ending on that day the actual coke production in the Connells-ville and Lower Connells-ville region, according to the report of the Connells-ville *Courier*, was 191,600 tons, a decrease of 71,210 tons, or 27 per cent, from the output of the preceding week, when the output was larger than the November average, which was to be taken in figuring the decrease. This was a good showing from the blast-furnace standpoint, but in the week following the production has not materially increased and may indeed prove to have been a trifle less. The difficulty was in car supply. The week opened with 100 per cent car supply on Monday, this decreasing to 70 per cent the next day and to 40 per cent the day following, while for Saturday few if any cars were expected. The railroads do not seem to have been affected as much as in previous years by the first real cold snap of the season, but they were very busy with coal movement. The Monongahela Railroad in particular was practically congested with loaded coal. The blast-furnaces may not be in easy position in the matter of coke until the early part of January, particularly as the holidays always produce troubles of their own in the matter of coke production. Few furnaces have banked or will have to bank, but quite a number have slowed down. Moderately large stocks had been accumulated by many furnaces before the pinch came.

PIG IRON ADVANCE CONTINUES

The Philadelphia and Buffalo pig iron markets have gone up \$1 a ton, and so has the Southern market. Prices at valley furnaces are up \$1 on bessemer and \$2 on basic, while foundry iron has now brought for second quarter the same price previously ruling for prompt and early deliveries only. The market on foundry iron now stands as follows: Philadelphia, \$41.10; Buffalo, \$40; Cleveland, \$38.40; Chicago, \$40; Birmingham, \$35. The valley market stands at \$36 for bessemer, \$35 for basic and \$38 for foundry, irrespective of delivery.

The pig iron markets have been showing signs of quieting down and precedents will be broken if the next fortnight, on account of the holidays, is not decidedly quiet. While some merchant furnacemen predict a continuation of the advance next year, it has been noted in past years that the market does not automatically resume, after a holiday dullness, where it left off, but requires a fresh impetus. With consumers apparently fairly well covered for the next few months, this impetus may not be furnished.

STEEL SCARCITY SPREADS

Measured by the descriptions of steel for which premiums, or advances over the March 21 price schedule, can be secured, the steel scarcity has spread, since plates are now on the list. A month ago plates could be had on attractive orders at 2.50c., against the 2.65c. price in the March 21 schedule, but in the past few days lots of 1000 tons and over have gone at 2.75c. for delivery over a few weeks. The Steel Corporation's price, of course, remains at 2.65c., and indeed the corporation has made various tenders in the past few months to the Navy Department at 2.50c.

The wire nail situation is not relieved, the wire mills having particular difficulty in getting output from their nail departments. Some descriptions of spring wire are very scarce. Hot and cold rolled strip continue extremely scarce.

Throughout the steel industry much difficulty is experienced in getting tonnage results. There is both a shortage of men and a low level of morale and efficiency. The iron and steel strike is over, so far as there being any number of men still on strike, but some men have drifted into other employments. Even the Wheeling district, the last to hold out, is done with the strike. The two pipe mills in the district are already in partial operation, also the La Belle and Laughlin tin plate plants. The Yorkville plant has been operating for several weeks.

The Ferro-Alloy Market

The market during the past week has been flat, displaying nothing of particular interest in prices, demand or supply.

Ferrochrome, 6-8 per cent carbon contained, dropped from 23-24c. per lb. to 19-20c. per lb., while 4-6 carbon contained lowered to 21c. per lb., against 25c. of the previous week. There has been a brisk market on *molybdenite*, 85 per cent MoS₂, which is being quoted nominally at 75-85c. per lb., with very little available.

There is a moderately good demand for *ferromanganese*, and domestic makers have made several sales at their recently advanced price of \$120, delivered. Reports are that offerings of English *ferromanganese* have appeared again, sales being made at \$110, c.i.f., but with no quotations out now at that figure. *Spiegeleisen* is \$38 to \$40, f.o.b. furnace.

Electrolytic ferrosilicon has advanced lately and is now held at \$90 for 50 per cent and at \$140 to \$150 for 75 per cent, delivered Pittsburgh, Cleveland, etc. Bessemer ferrosilicon is quoted as follows: 10 per cent, \$59.50; 11 per cent \$62.80; 12 per cent, \$66.10, f.o.b. Jackson, Ohio.

The Chemical Market

New York, December 19, 1919.

The market of the past week compared with the previous report is easier; prices have remained firm but demand has fallen off slightly, which is partly due to the fact that inventories are being taken.

Sodium bichromate, which has been soaring lately and has been quoted as high as 45c. per lb., has had a turn, and with the present stock on hand the price has dropped to 19-25c. per lb. The low end of the *formaldehyde* quotation has dropped to 20c., which makes the present listing 20-37c. per lb., while *caustic soda* is scarce and has jumped from \$3.80 per cwt. to \$4.30. The hoarding of silver in India and China is one of the causes of the scarcity of that metal which in turn placed *silver nitrate* on a very unstable footing. The quotation at the present writing is 818-828c. per oz., but with the present fluctuation this price will probably change within the hour. There is no *denatured alcohol* available and the price has jumped from 72-78c. to 80c. per gal. on 188 proof and from 68 to 76c. per gal. on 190 proof.

The future of the *coal-tar* industry is especially bright and increased activity is expected in both foreign and domestic markets. Foreign inquiries have not been so heavy during the past week. *Dimethylaniline* is still in large demand and has come up to a high mark of 92c. per lb., as contrasted with 85c., the corresponding figure of last week. The present quotation on this item is from 60 to 92c. per lb. *Aniline salts* at present are active at 40-42c. per lb., against 37c. of last week, while *aniline oil* also advanced from 34-35c. per lb. to 35-36c. Very little *phenol* remains on the market, most of the output being already sold. A nominal quotation of 123-16c. per lb. still remains.

The *waxes* continue firm, with especial activity in the paraffine grades. Demand is still a step ahead of supply in these lines, but there has been no material change in prices. In the *flotation oils* demand is rather brisk, with the Government price of \$1.25 per gal. still in effect on the pine oil steam dist. sp.gr. 0.930-0.940 and \$1 on the pure dist.

There has been a slight falling off of foreign inquiry in *naval stores*, but prices remain the same. The low prices mentioned last week are holding in the Southern market, which tends to stabilize New York quotations.

In the *crude rubber* market up river fine dropped to 47-48c. per lb., against 53-54c. per lb. of last week, while first latex went up to 52c. compared with 51c. of the previous report. There has been very little activity in this line, rubber buyers seeming to have ample stocks.

Linseed oil has been under considerable inquiry and there has been a slight advance in price, raw car lots being quoted at \$1.90 against \$1.87 per gal. last week, and raw tank cars at \$1.85 per gal., compared with \$1.83 a week ago.

The Government prices of *coke* remain unaltered, foundry being listed at \$6 and furnace at \$7 per ton; the output of furnace coke has been greatly increased to meet the large demand.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	\$0.20	\$0.60-\$0.65
Acetone.....lb.	\$0.20	21 - 3.25

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....lb.	\$1.00 - \$1.10
Alpha naphthol, refined.....lb.	1.40 - 1.50
Alpha naphthylamine.....lb.	32 - 35
Aniline oil, drums extra.....lb.	30 - 36
Aniline salts.....lb.	40 - 42
Anthracene, 80% in drums (100 lb.).....lb.	90 - 100
Benzaldehyde (f.f.c.).....lb.	1.00 - 1.15
Benzidine, base.....lb.	90 - 100
Benzidine, sulphate.....lb.	90 - 100
Benzoic acid, U. S. P.....lb.	80 - 100
Benzoate of soda, U. S. P.....lb.	80 - 100
Benzol, pure, water-white, in drums (100 lb.).....gal.	21 - 21
Benzol, 99% in drums (100 lb.).....gal.	25 - 29
Benzyl chloride, tech.....lb.	35 - 40
Beta naphthol benzene.....lb.	25 - 35
Beta naphthol, refined.....lb.	75 - 82
Beta naphthol, tech.....lb.	45 - 55
Beta naphthylamine, sublimed.....lb.	2.25 - 2.35
Cresol, U. S. P., in drums (100 lb.).....lb.	23 - 25
Ortho-cresol, in drums (100 lb.).....lb.	80 - 85
Creosylic acid, 95-97% straw color, in drums.....gal.	85 - 90
Creosylic acid, 50% first quality, drums.....gal.	85 - 90
Dichlorobenzol.....lb.	1.00 - 1.10
Diethylaniline.....lb.	1.40 - 2.25
Dimethylaniline.....lb.	60 - 92
Dinitrobenzol.....lb.	26 - 37
Dinitrochlorobenzol.....lb.	25 - 30
Dinitrophenylamine.....lb.	45 - 55
Diphenylamine.....lb.	32 - 36
Diphenylamine, H.C.L.....lb.	38 - 45
Diphenylamine, H.C.L.....lb.	38 - 45
H-acid.....lb.	60 - 75
Metaphenylamine.....lb.	1.15 - 1.80
Monochlorobenzol.....lb.	1.12 - 1.15
Mononethylaniline.....lb.	1.50 - 1.75
Naphthalene crushed, in bble. (250 lb.).....lb.	06 - 08
Naphthalene, flakes.....lb.	06 - 07 1/2
Naphthalene, balls.....lb.	08 1/2 - 10
Naphthionic acid, crude.....lb.	75 - 125
Nitrobenzol.....lb.	14 - 19
Nitro-naphthalene.....lb.	40 - 45
Nitro-toluol.....lb.	27 - 30
Ortho-amidophenol.....lb.	3.00 - 4.25
Ortho-dichlorobenzol.....lb.	13 - 15
Ortho-nitro-phenol.....lb.	25 - 40
Ortho-nitro-toluol.....lb.	25 - 40
Ortho-toluidine.....lb.	25 - 30
Para-amidophenol, base.....lb.	2.50 - 3.25
Para-amidophenol, H.C.L.....lb.	2.50 - 3.25
Para-dichlorobenzol.....lb.	15 - 18
Paranitraniline.....lb.	1.15 - 1.25
Para-nitro-toluol.....lb.	1.35 - 1.50
Paraphenylenediamine.....lb.	2.50 - 4.00
Paratoluidine.....lb.	2.00 - 2.15
Phthalic anhydride.....lb.	1.50 - 2.15
Phenol, U. S. P., drums (deut.), (240 lb.).....gal.	1.24 - 1.60
Pyridin.....lb.	3.75 - 4.00
Resorcin, technical.....lb.	6.50 - 6.75
Resorcin, pure.....lb.	45 - 60
Salicylic acid, tech., in bble. (10 lb.).....lb.	45 - 50
Salicylic acid, U. S. P.....lb.	45 - 50
Solvent naphtha, water-white, in drums, 100 gal. gal.....lb.	22 - 27
Solvent naphtha, crude, heavy, in drums, 100 gal. gal.....lb.	24 - 29
Sulphanilic acid, crude.....lb.	25 - 30

Tollidine.....	lb.	\$1.70	\$2.50
Tollidine, mixed.....	lb.	.45	.55
Tolol, in tank cars.....	gal.	28	30
Tolol, in drums.....	gal.	32	30
Xylydine, drums, 100 gal.....	lb.	44	50
Xylol, pure, in drums.....	gal.	37	45
Xylol, pure, in tank cars.....	gal.	35	45
Xylol, commercial, in drums, 100 gal.....	gal.	37	45
Xylol, commercial, in tank cars.....	gal.	23	27

Waxes

Prices based on original packages in large quantities.

White lead, dry and in oil, 100 lb. keg.....	lb.	13	..
White lead, dry and in oil, 25 and 50 lb. kegs.....	lb.	13	..
White lead, dry and in oil, 5 lb. cans.....	lb.	15	..

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45	..
Angles, 3 to 6-in. by 3-in.....	100 lb.	2.45	..
Tees, 3-in. and larger.....	100 lb.	2.45	..
Plates.....	100 lb.	2.66	..
Rivets, structural, 3-in. and larger.....	100 lb.	4.20	..
Rivets, common for boilers, 1-in. and larger.....	100 lb.	4.35	..
Sheets, No. 10 black.....	100 lb.	4.35	..
Sheets, No. 12 blue annealed.....	100 lb.	3.55	..
Sheets, No. 28 galvanized.....	100 lb.	5.70	..

For painted corrugated sheets, add 30c. per 100 lb. for 25 ft. x 28 gauge; 25c. for 19 to 24 gauge; for galvanized corrugated sheets, add 15c., all gauges.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

NOTE—These items were compiled as of Dec. 22, but appear in this issue due to the delay in publication due to the printers' strike.

California

LOS ANGELES—The Los Angeles Soap Co., 633 East 1st St., is having plans prepared for the construction of a 30 x 40 x 80 ft. distillery building, in connection with its soap factory at 1st and Alameda Sts. Morgan, Walls & Morgan, 1124 Van Noy St. Bldg., architects.

Connecticut

WATERBURY—The Scoville Manufacturing Co., 99 Mill St., will build a 1-story, 30 x 100-ft. paint shop and 1-story, 12 x 22-ft. addition to its sub-station on Silver St. Estimated cost, \$23,000. Work will be done by day labor.

Illinois

JACKSONVILLE—The city clerk will receive bids in January for the construction of a 1,500,000-gal. capacity filtration plant. Estimated cost, \$50,000. S. A. Greeley, 33 West Adams St., Chicago, engineer.

Louisiana

MONROE—The city voted \$1,450,000 bonds, part of which will be used for improvements to the waterworks, including a 3,000,000-gal. capacity filtration plant.

Massachusetts

WESTFIELD—The Vittrified Wheel Co., Emery St., will soon award the contract for the construction of a 2-story, 42 x 85-ft. manufacturing plant. Estimated cost, \$25,000.

Michigan

DETROIT—The Detroit Motor Castings Co., Beaufait St., will receive bids in March for the construction of a 1-story, 60 x 155-ft. brass foundry, to J. L. Hopkins, Sun Bldg. Estimated cost, \$35,000. Noted Oct. 22.

LANSING—The Allyn-Ryan Foundry Co., Aetna Rd., Cleveland, has awarded the contract for the construction of a 1-story, 300 x 400-ft. gray iron foundry, to the Christianman Construction Co., 302 Union Trust Bldg., South Bend, Ind. Estimated cost, \$300,000.

Minnesota

COLERAINE—A. King, secretary of the Board of Education, will receive bids in March for the construction of a 2-story, 150 x 270-ft. high school in the Canistes District. A special laboratory and a science department will be installed in same. Estimated cost, \$50,000. W. T. Bray, Torrey Bldg., Duluth, architect and engineer.

Montana

HARDIN—The city has awarded the contract for the construction of a water filtration plant, including a 2-story, 39 x 56-ft. building, a 30 x 44-ft. filter building, with a capacity of 1,000,000 gal. per day, and a 32 x 56-ft. coagulating basin, to the Security Bridge Co., 502 East 32nd St., Billings. Estimated cost, \$89,517.

New Jersey

NEW BRUNSWICK—The city plans to issue \$13,000 bonds for the construction of additional units at the filtration plant.

New York

COLLEGE POINT—The American Hard Rubber Co. is having plans prepared for the construction of a 1-story, 120 x 130-ft. factory addition, to Walter Kidde, 149 Cedar St., New York City, architect and engineer.

LONG ISLAND CITY—The G. M. Film Printing Co., Times Sq., New York City, has awarded the contract for the construction of a 2-story, 35 x 155-ft. film

laboratory at Pierce and 8th Sts., to the Fleischman Construction Co., 531 7th Ave., New York City.

ROCHESTER—The city will build a large garbage and sewage disposal plant. Modern equipment will be installed in same.

ROCHESTER—The Josiah Anstice Co., Inc., plans to construct a 1-story, 145 x 216-ft. foundry building on Humboldt St. Estimated cost, \$85,000.

SYRACUSE—The Mills Oil Co., 263 Walton St., plans to build 4 or 5 buildings, including an oil and gasoline building, on North Clinton St. Estimated cost, \$200,000.

UTICA—Peter E. Hoffman, 2234 Whitesboro St., plans to construct a 1-story, 50 x 500-ft. factory building on Sunset Ave. Molding machines, equipped with individual motors to manufacture 5000 concrete building blocks daily, will be installed in same. Estimated cost between \$40,000 and \$45,000.

WATERTOWN—The Board of Water, Light & Power has engaged Hazen, Whipple & Fuller, architects, 30 East 4th St., New York City, to prepare plans for a settling basin to be added to the present water filtration system. Estimated cost, between \$60,000 and \$80,000.

North Dakota

DUNSEITH—The Board of Control is having plans prepared for the installation of a water-softening plant in the State Tuberculosis Sanitarium here. Estimated cost, \$5000.

MAYVILLE—The city plans an election soon to vote on \$10,000 bond for the installation of a water-softening plant. A Joudet, city engineer.

Ohio

CANTON—The Weber Dental Manufacturing Co., 400 Cherry Ave., plans to construct a factory addition. One part will be used as an addition to the brass and aluminum foundry and another to the plating and polishing department. Estimated cost, \$50,000.

CHILLICOTHE—The Mead Paper & Pulp Co. is having plans prepared for the construction of two buildings; 152 paper machines will be installed in same. Estimated cost, \$60,000.

CLEVELAND—The Aetna Steel Castings Co. has awarded the contract for the construction of a 1-story, 20 x 35-ft. addition to its foundry at 2284 Scranton Rd., to W. I. Thompson, 5103 Euclid Ave. Estimated cost, \$5000.

CLEVELAND—The city will soon award the contract for the construction of twelve 8 x 50-ft. grit chambers, flow channels, etc., in connection with the Eastern Sewage Treatment Works, foot of East 140th St., G. Gascolne, 618 City Hall, engineer.

CLEVELAND—The Parish-Pool Copper Co., care of Paul E. Cleveland, Guardian Bldg., has awarded the contract for the construction of a 1-story, 150 x 500-ft. smelting and refining building on Clinton Rd., to A. W. Kilbourne Co., 6532 Euclid Ave. Estimated cost, \$300,000.

COLUMBUS—The Columbus Dental Co., 624 Wagner St., engaged Otto Darst, architect, Brunson Bldg., to prepare plans and submit estimates for the construction of a 2-story, 38 x 100-ft. addition to its factory, including a 2-story, 35 x 60-ft. office building. Estimated cost, \$40,000.

DAYTON—The Miami Brass Foundry Co., McDonough and Bacon Sts., plans to build a 3-story, 75 x 120-ft. factory on McDonough St. Estimated cost, \$100,000.

Tennessee

WILKES-BARRE—The Wyoming Valley Homeopathic Hospital, Dana St., plans to build a 4-story, 40 x 50-ft. hospital and will be in the market for laboratory equipment. Estimated cost, \$50,000.

Texas

BRECKENRIDGE—The Texas Co., 17 Battery Pl., New York City, has awarded the contract for the construction of a compressor and absorption plant, to Westinghouse, Church, Kerr, Inc., 37 Wall St., New York City. Estimated cost, \$150,000.

CORSICANA—The Corsicana Oil & Refining Co. plans to build an oil refinery here. Estimated cost, \$300,000. W. M. Elliott, 1004 West 3rd Ave., engineer.

WEST DALLAS (Dallas, P. O.)—The Monarch Petroleum Co. has purchased a 30-acre site here and plans to construct a 5000-bbl. refinery on same. Estimated cost, \$500,000. J. R. Alkon, Western Indemnity Bldg., Dallas, president.

Wisconsin

FORT ATKINSON—The Creamery Package Manufacturing Co., Fort Atkinson Bldg., has awarded the contract for the construction of a 2-story, 40 x 30-ft. enameling plant, to the Bault Co., Patton Bldg., Milwaukee. Estimated cost, \$25,000.

KEWASKUM—The Kewaskum Aluminum Co. has awarded the contract for the construction of a 2-story, 50 x 180-ft. factory, to John J. O'Neil, 144 Oneida St., Milwaukee. Noted Oct. 23 and Nov. 5.

MANITOWOC—The Aluminum Goods Manufacturing Co., 15th and Franklin Sts., has awarded the contract for the construction of a 1-story, 300 x 100-ft. rolling mill, to W. W. Oeffel, 86 Michigan St., Milwaukee. Estimated cost, \$300,000.

MILWAUKEE—The Pfister-Vogel Leather Co., 443 Virginia St., has awarded the contract for the construction of a 1-story, 150 x 300-ft. tannery at 2nd Ave. and Virginia St., to the Dahlgren Construction Co., Majestic Bldg. Estimated cost, \$125,000.

WEST ALLIS—Arthur Schneider, State Sanitary Engineer, City Hall, has recommended the reconstruction of the west end sewage disposal plant. Estimated cost, \$10,000.

WEST BEND—The West Bend Aluminum Co. has awarded the contract for the construction of a 4-story, 72 x 144 x 132-ft. L shaped factory, also a 1-story, 72 x 120-ft. building, to the Northern Construction Co., Colby-Abbot Bldg., Milwaukee. Estimated cost, \$100,000. Noted Oct. 23 and Nov. 5.

Ontario

FERGUS—J. Alpaugh & Son have purchased a site and are preparing plans for the construction of a modern marble works on same. Estimated cost, \$25,000.

TORONTO—Appleen & Chimpman, consulting engineers, 100 Wellington St., E., are in the market for filter presses, feed dryers, etc.

Quebec

MONTREAL—B. J. Coghlin and Co., Ltd., 2050 Ontario St., will soon award the contract for the construction of a 2-story, 40 x 108-ft. factory for the manufacture of oils and greases, on Ontario St. Estimated cost, \$18,600.

MONTREAL—The Canada Sugar Refining Co., 340 Fortmoyne St., has awarded the contract for the construction of a 3-story, 20 x 53-ft. sugar factory on Montmorency St., to the Church-Ross Co., Ltd., 60 Cathcart St. Estimated cost, \$17,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a meeting in St. Louis from Dec. 26 to Jan. 1.

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23-26.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9, and 10.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York, Feb. 16-19.

THE AMERICAN PRIVATE SOCIETY will hold a meeting in St. Louis from Dec. 26 to Jan. 1.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

THE MINING AND METALLURGICAL SOCIETY OF AMERICA will hold a meeting in New York Jan. 13.

Number 15

Optimists in Spite of Appearances

IT WOULD not be difficult even for an optimist to indulge in lugubrious feelings by retrospect on the year that is ending. Hailed with delight because hostilities in Europe had ceased and peace was in prospect, Nineteen Hundred and Nineteen has been a distinct disappointment in many respects, and few, probably, will mark its passing with regret. Industrial strikes during the year were numbered literally by the hundred, and the man who has not suffered inconvenience more or less acute by reason thereof must indeed be an individual of small consequence or one having slight contact with the world of affairs. In fact, turmoil and unrest have been so marked and have so directly affected the daily life of the people that cynical commentators have been led to contrast the serene period of the war with the stormy aftermath of the Armistice.

Consideration of the Treaty, abortive in its results due to the rôle played by partisan politics, has prevented Congress from giving needful attention to legislation on water-power development and tariff regulation on such commodities as dyes, potash, optical and chemical glass, porcelain and certain metals and minerals. All data essential to the information of Congress on these subjects have long since been presented by the Tariff Commission and representatives of the industries, and committee reports have been prepared as a result of extended hearings.

But if the year's events afford occasion for dissatisfaction, we still believe that

Sweet are the uses of adversity,
Which, like the toad, ugly and venomous,
Wears yet a precious jewel in its head.

If our own experience with arbitrary and unreasonable strikes, called and directed by irresponsible leaders, points a moral, and if the reaction of our subscribers and advertisers can be taken as typical of public sentiment toward such actions, we are constrained to believe that the strike has lost much of its force as a weapon of offense for Labor. If this be true, we will indeed have discovered a "precious jewel" which Labor itself may yet come to admire. And this is said in all sincerity and with cordial interest in the just deserts of Labor, for it has always seemed to us incongruous in the extreme that the most effective weapon thus far developed by Labor—the strike—should react against its intended beneficiaries, often with fatal force. We are confident that the future will develop new and more effective, as well as peaceful, means for preserving industrial peace and averting the deplorable deadlocks that have characterized the past year. A good omen in that respect is the preliminary report of the President's new Industrial Conference, which we shall discuss later.

Applied Economics

IT IS good advice that the people should be taught economics. It would be well if, instead of our being a nation of economic illiterates, we all knew at least the rudiments. But it is easier to say "teach economics" than to do it, and it does not follow, moreover, that if the people were taught economics they would act in the light thereof.

As to our domestic affairs, the thing desired is that men should be brought to a realization that we cannot have goods without producing them, that no large number of men can hope to profit at the expense of other men, by producing less than they should and getting higher wages than they are entitled to. Suppose every man and every youth were taught the principles of economics, what would be the value except in the application? What would move the individual to act upon the knowledge and alter his conduct?

Applied economics is what is needed, but it is rather difficult to expect much good to come from the individual applying his knowledge of economics once gained. There is a fine opportunity, however, for economic studies to be made and the results or findings to be placed before the public. A great deal of work is now done in the collection of statistics of prices of commodities, whereby the public is given information relating to the cost of living. While it may be of interest to know that in a given period the average price of commodities, or the cost of living, has increased or decreased by a certain percentage, yet it would be much more useful if information were secured as to why the change had occurred. It may be helpful in settling a labor dispute to cite facts as to what it costs the workman to live, but labor disputes frequently arise because the workman is not producing as much as the laws of economics would dictate. Instead of thinking only of what the workman ought to be able to buy with his wages, it would be well to think also of what services he proposes to render for those wages.

This continued dealing in averages, of commodity prices and wage rates, tends to becloud the situation instead of throwing light upon the way out. The public should be informed of specific facts. For instance, coal miners do not work full time. That is economically improper, yet recently the coal miners demanded a 60 per cent increase in their rate for mining a ton of coal, on the very ground that they work less than 200 days in the year.

Individual industries could study their economic results to advantage and those that can make a good showing would find it advantageous to make the facts public. Those that cannot should seek to improve their condition. At present it is easy to show at least one wide

divergence in price relations. Thus: Bradstreet's index number of all commodities now stands at 125 per cent above its ten-year pre-war average 1904 to 1913 inclusive. The finished steel prices promulgated March 21, which the United States Steel Corporation has taken the lead in adhering to despite requirements in excess of the supply, are up only 81 per cent. The steel industry does not show this low percentage through having been backward in advancing wages, but rather because the bulk of their men must follow the machinery and therefore have not decreased as much in efficiency as has been the case in some other industries.

Those industries that have exerted the strongest influence in pulling up the index number should be studied to see what is wrong with them.

Fuel Oil Combustion And Conflagration

FOR some time the various municipal authorities throughout the country have been studying the question of legal regulations governing the storage and use of fuel oil. That some kind of rules will shortly be adopted is certain, but whether they will be practical or not will largely depend on the experience and motive of the drafters. Of course if the result desired is an absolute prevention of fuel oil conflagrations, rules can be made with a margin of safety as wide as the ocean. In this case the high cost of engineering and equipment would soon offset any advantages in burning oil as fuel. This would please the city fire chiefs, because most of them are mainly concerned with extinguishing fires and naturally lend their testimony in support of rules which will entirely eliminate oil conflagrations regardless of other important considerations.

The rules as finally adopted should not be influenced by extremists on either side of the question. Men equipped with a far-reaching view of the broad economics of both fuels and fire hazards should assert themselves. There are these among the consumers and producers. The latter, being effectively organized in the American Petroleum Institute, are acting concertedly. It is for the attention especially of the former that we have included a discussion of a tentative draft of regulations in this issue.

Shape of Metallic Crystalline Grains

ON ANOTHER page is printed a portion of Dr. DESCH's second report on the solidification of metals, in which he discusses some evidence bearing upon QUINCKE's hypothesis, that immediately before solidification a liquid expels a small amount of immiscible fluid which arranges itself in cell walls, within which solidification of the main mass proceeds. A marked similarity between foam cells and crystals of β -brass disintegrated by mercury is actually found, but crystalline grains of other metals could not be isolated in sufficient number to yield useful data.

While a study of crystalline boundaries developed in a micro-section gives little light upon their spatial dimensions, one cannot help feel that photographs of a succession of parallel sections could be used to build up crystal shapes much as a relief map is constructed from contour lines. Thus, a small block of metal might be placed in a fixture so that successive surfaces could be ground exactly parallel to each other, and a closely referenced area successively photographed at uniform

magnification. The thickness of metal removed might be determined by caliper or balance and each micrograph mounted on a sheet of wood of corresponding thickness. This could then be cut apart along the crystal boundaries, and each section glued in correct orientation and position to the corresponding ones from the preceding photographs. A tedious job, but well within the skill of many model makers.

Such solid forms, capable of reproduction, would be of great value in an investigation like this, and would at the same time check various ideas regarding the relation between grain size and counts from a micrograph.

One reservation must always be borne in mind when trying to determine the mechanism of solidification by the use of such crystalline studies, and that is the obvious fact that the history of the metal subsequent to its solidification has a profound influence on the eventual grain shape. It may very well be that the cellular structure of freshly solidified metal is unstable at lower temperatures, and the heat residing in the ingot during cooling is sufficient to modify profoundly its constitution. The efficacy of drastic quenching may not be doubted in some cases, although in others it does not prevent an astounding amount of molecular migration.

A successful conclusion is to be wished for Dr. DESCH's most difficult problem. It will doubtless yield immense immediate light into the structure of pure metals; it may clear up perplexing and expensive troubles with impurities in melts. But as is usual with that dubbed "pure research," the eventual effect of a clear insight into the mechanism of solidification cannot now be dreamed.

The Forest Products Laboratory Valued Servant of the Industries

GOVERNMENT institutions are akin to business firms in that they have individuality, determined largely by the economic benefit each renders to the population served. If a commercial project is not based on the principles of real assistance to the community, it fails, but on the contrary, as the service becomes of increasing value, the firm prospers in fulfillment of the owner's expectations.

A government organization backed with initial appropriations can, within a comparatively short time, procure results much needed for the public welfare, thus immediately taking its place among recognized institutions.

Then appears a marked difference in the progress of the two, for the business organization receives return directly and almost in proportion to value given, while the government body, the public itself serving the public, enjoys no immediate return to the unit performing. It must needs wait until through general appropriation, involving the long process required to remove money from one pocket to the other, the necessary funds are made available to the institution. The full growth of the deserving government organization is thus frequently hampered in periods of rapid development.

Sharply and distinctly outlined against the background of lethargic governmental departments, standing to the fore in largeness of service and economic return to business industrial, is the Forest Products Laboratory. Published elsewhere in the pages of CHEMICAL & METALLURGICAL ENGINEERING, an article under the title "The Forest Products Laboratory" re-

counts in detail some of the things accomplished by this institution. In no less proportion than the ensemble of the industries of the United States, the chemical and chemically controlled industries are benefited by the activities of the Laboratory.

The Laboratory is supported by Federal appropriation amounting to \$175,260 annually, for the year beginning July 1, 1919, which is no greater than the pre-war figure. During the war its activities were greatly increased and supported by additional allotments from the War and Navy Departments. These have been largely withdrawn, leaving the organization dependent on the funds inadequate to support the natural growth—inadequate because of the depreciation of the buying power of the dollar—and especially insufficient to cover the necessary research in adaptation of valuable war-time discoveries to peace-time production.

A committee composed of representatives from a number of national associations, covering the industries most vitally interested in the service rendered by the Laboratory, after careful investigation, hold the opinion that an annual appropriation of not less than \$500,000 should be made by Congress. The committee further finds that this amount could not be safely reduced without great loss to the public, the ultimate beneficiary of the Laboratory's output.

The cause is worthy, the need for adequate appropriation for housing and maintenance is immediate, and it only remains for the individuals at interest, namely, the whole public, to push the wheels through Congressional representatives. We are glad to lend our support to the movement and urge all engineering and scientific organizations to do likewise.

The Future of Commodity And Property Values

THUS far there has been little trend toward the correction of the anomaly left by the inflation the war caused, of commodity values, in dollars, being increased much more than values of fixed property by comparison with values before the war. It costs about twice as much to build a dwelling house as it did two or three years ago, and perhaps three times as much as 20 years ago, by reason of materials costing more, labor costing much more per day, and labor doing much less work in a day, but on the other hand the houses already built have not increased in market value in any such ratio. Inasmuch as houses have to be built as the population increases and old houses wear out, one would suppose that the value of the old house and the cost of producing a new house would tend to come together.

As to land values the case is different. Land is not produced, but the owner of land expects revenue and he would like to have his revenue, buy him as much in commodities or labor as it did before the inflation occurred.

There is to be a resolution of forces, of course, according to immutable laws, but one does not know precisely what the laws are or what are the relative amounts of the forces or their angles.

There are many who argue that the decreased value of the dollar is simply a permanent thing, and all values that are expressed in dollars must be correspondingly increased, if they have not already been increased. The application of the theory, however, encounters difficulties of various descriptions and degrees. There are high school teachers who complain that they are receiving less wages than street sweepers.

Possibly that situation can be remedied, but there are many billions of bonds whose holders can of course obtain no relief. Holders of stock may be given relief by dividend rates being increased, or by stock dividends being declared in case the Supreme Court decides that stock dividends are not taxable as income. There is no disposition to double freight and passenger rates, the increases that have occurred being regarded as relatively heavy as it is.

There is always a way to get around things, however, if it is absolutely necessary to get around. In a given industry, for instance, wages advance by an amount out of proportion to the general alignment of affairs, and then the introduction of labor-saving machinery is encouraged, whereby eventually the labor cost of production is brought to a lower level than ever.

There are some restraining influences to the increase in value, measured in dollars, of fixed property. For the purpose of the present argument it does not matter what the influences are. The cost of duplication being greatly advanced, increases in the number of dwelling houses, of power plants and other kinds of property are somewhat discouraged. Correspondingly, there is a greater incentive to secure efficiency from such property as exists or is to be built. More families can be accommodated in apartment houses, with the same capital, than by building separate dwellings. By better design and better machinery power plants can be made more productive.

In other words, efficiency will make greater strides in some quarters than in others. As a rule improvements are forced rather than spontaneous, and where there is the most pressure there the greatest progress will occur. The public service corporation, that cannot double the book value of its property, its charges and its dividend rate, must make its property more efficient.

One must remember that the affairs of men are produced by men. It is what is in men's minds. Some theorists would have it that if the amount of the circulating medium is increased by a certain percentage, then all prices will automatically advance by a certain percentage. There is nothing automatic about it. A suggestion along this line is furnished by the New York stock market, which is held to represent actual values, but those wise in Stock Exchange doings assert that "stocks never advance; they are put up." In other words, the shares may be entitled to bring higher prices but they do not bring the higher prices without assistance. Price advances in the commodities that are bought by the general public occur largely according to the mental attitude of buyer and seller. If the seller is courageous and the buyer careless the price advances. If the buyer really cannot afford to pay the advanced price, or curtails his consumption, the price is likely to fall. It would be marvelous indeed for the people to get along at all if all their complaints about "the high cost of living" are really true. The individual complains of the advance in the unit price but says nothing about his ability to get along quite comfortably with a smaller number of units. Eventually there will be found room for commodity prices to come down somewhat, though probably not in this period of strikes, restricted production and general carelessness in spending. Property values, on their part, will probably advance somewhat, and a few years hence commodity and property values will probably be found to be in somewhat the same relation as before the war.

Western Chemical and Metallurgical Field

Silicomanganese Furnace Production Record

SILICOMANGANESE was produced in this country as a result of the war demand for steel deoxidizers. It has the advantage over ferromanganese in that it can be easily produced with a low carbon content and from manganese ores high in silica. Although not used in this country to any large extent, silicomanganese has been very favorably considered and used in quantities in England, France, Russia, the Scandinavian countries and Germany; in the latter country very extensively during the war. It is considered to be a more active deoxidizer than either ferromanganese or ferrosilicon alone.

A furnace was designed and erected by the Beckman & Linden Engineering Corporation of San Francisco during the spring of 1918. The furnace is of the open-top design, rectangular in plan, 9x17 ft. outside dimensions; of 3000-kw. capacity, using 60-cycle, 3-phase current operating at 90 volts between phases. The general

ported from an overhead jib. The cooling water for the holders flows through the copper conductor pipe. The furnace is tapped by burning through the refractory plug and solidified metal at the tap hole with a graphite rod which is electrically connected to one phase during this operation. Charging is done by hand from the platform, the furnace being of sufficient height above the platform to protect workmen from excessive heat.

The table gives the consumption of raw materials, electrodes and power for the first fifteen days of August, 1918. Average weight of electrodes 1180 lb. Average analysis of manganese ore charged was 39.5 per cent Mn, 23 per cent SiO₂. The Segundo coke from Colorado, which was used during the test, averaged 14 per cent ash. The entire charge was melted to alloy, no slag being formed. The manganese recovery averaged 93.6 per cent, the loss being caused principally through volatilization.

CONSUMPTION OF RAW MATERIALS, ELECTRODES AND POWER

Date, 1918, Aug.	Silicomanganese Produced, lb.	Per cent Mn in Product	Mn Ore, lb.	Silica, lb.	Coke, lb.	Scrap Steel, lb.	Electrodes, No. Used, 20 in. Diameter	Power, Kw.-hr.

Average analysis of silicomanganese produced: Mn, 53.30 per cent; Si, 23.12 per cent; Fe, 23.00 per cent; C, 0.40 per cent; P, 0.18 per cent.

Alaska's Mineral Production

Regular mining in Alaska may be said to have been begun in 1880 when the Juneau gold placers were first exploited. Since that time the value of the mineral wealth produced has been estimated at more than \$418,000,000. During 1918 the mineral production was valued at \$28,254,000, which is less than that for 1917 by \$12,500,000. This decrease was chiefly in copper, which fell from 88,783,400 lb. valued at \$24,240,598 in 1917 to 69,224,951 lb. valued at \$17,098,563 in 1918, the reduced output being due to the shortage of labor and ships. There was also a reduction of the output of gold, silver, lead, tin and tungsten due to scarcity of labor and the high cost of supplies. The production of antimony practically ceased because of the inability of the producers to compete with the cheaper foreign product. The production of coal, however, increased from 53,955 tons valued at \$265,817 in 1917 to 75,606 tons valued at \$411,850 in 1918. The production of platinum, which began in 1916, continued on an increasing scale.

According to current reports from the U. S. Geological Survey, twenty-eight gold dredges produced \$1,450,000 worth of gold from 2,490,000 cu.yd. of gravel. In 1917, 36 dredges handled 3,700,000 cu.yd. of gravel and recovered gold worth \$2,500,000. The total value of the gold produced by dredges to the end of 1918 is es-

3000-KW. SILICOMANGANESE FURNACE

design is shown in the accompanying drawing, with dimensions, showing a side elevation and a plan view. The electrodes are hexagonal in shape, 20 in. in diam., this form being chosen as giving better contact between holder and electrode. The flexible conductors from the closed delta are connected to a copper pipe conductor; the electrode, electrode holder and conductors are sup-

timated to be \$19,035,000. The value of the placer gold produced in 1918 was about \$5,900,000, compared with \$9,810,000 in 1917. The output of platinum, palladium and other metals of the platinum group for 1918 is estimated at 284 fine ounces valued at \$36,600. Substantial amounts of palladium and some platinum are recovered from the copper ore of the Salt Chuck Mine, near Ketchikan.

The tin mines of Alaska produced 136,000 lb. of metal valued at \$118,000 during 1918, a decrease of 64,000 lb. from 1917. During the year only one dredge was operated. A recent discovery of placer tin has been reported from Potato and Humboldt creeks, on the Seward Peninsula, and from Moran Creek, a tributary of Melozi River, where gravels are said to contain 2½ lb. of tin and 10c. worth of gold to the cubic yard.

The Alloys Research Association

THE Division of Industrial Research of the National Research Council, after a careful canvass of the situation and the many problems which merit immediate attention, has decided that perhaps the greatest number could be served by the formation of a co-operative association to engage in fundamental research in alloys. The Division fully recognizes the fact that a great deal of exceedingly valuable work has already been done in the alloy field, but it is also convinced that progress in many lines of manufacturing is arrested because of the lack of certain facts which are fundamental and that the solution of a number of manufacturing problems depends upon additional information which can only be obtained by intensive research.

The Division believes that these problems are so broad that no single organization or laboratory can profitably do the work as thoroughly as it needs to be done, and that the most satisfactory method is for the industry to undertake the work under its own control and at its own expense. The whole question has been discussed thoroughly by the Division itself, most of whose members are men with commercial experience and connection, and the provisional outline submitted below has been formulated with the co-operation of those men who are most familiar with conditions in the alloy field and who are themselves very closely identified with the remarkable progress which has thus far been made. These specialists represent both the users of alloys and those whose primary business it is to manufacture alloys for sale as raw materials.

The Division has been encouraged in its work by the excellent records made in those industries which have supported research on some co-operative plan, notably, the National Cannery Association and the Malleable Iron Manufacturers. In addition, a number of fellowships have been supported by associations and manufacturers in special fields with successful results and a substantial profit to themselves. It has been demonstrated that the most progressive concerns, which are commonly supposed to require no further assistance in research, frequently derive the greatest benefit due to their ability to apply the results of the association to better advantage in their own works.

This new organization, which will be known as the Alloys Research Association, will undertake systematic research into fundamental questions affecting pure metals and alloys, both ferrous and non-ferrous. An information service will be maintained to supply members

with summaries of technical information in the metal field, answer inquiries and assist the research workers by preparing monographs on each phase of a proposed research, analyzing and recording results of research, and editing material for publication.

The membership of the association will include individuals, institutes and other associations interested in the production and use of alloys as raw materials in manufacturing processes. Initially, each individual member will pay \$1000 annually for a minimum period of five years, while an institute will be assessed a larger sum, depending upon the extent of its membership and the importance of alloys to it. Upon recommendation of the Executive Board, problems of general interest will be studied at the expense of the association and the results made available to all members. A member may also have undertaken a problem in which he alone is interested, at cost, for his sole benefit.

Undoubtedly a special laboratory will sooner or later be required, but until the results of the work warrant it, it is proposed that existing laboratories be used whenever possible.

Every effort will be made to avoid duplication between the work of the association and that of other agencies in the field. Through the services of the Advisory Committee on Alloys Research, of which Mr. W. M. Corse is chairman, it will be possible to keep in touch with work now in progress or contemplated and the activities of the association be so guided as to co-operate with such work.

The proposed articles of association, which have been briefly summarized here, are set forth as tentative and provisional, for the purpose of inviting discussion and constructive criticism. Those interested are urged to contribute their views to the vice-chairman of the Division, addressing H. E. Howe, National Research Council, 1201 Sixteenth Street, Washington, D. C., at their early convenience.

The Robert W. Hunt Award

Capt. Robert W. Hunt has placed in trust in a Chicago bank the sum of \$5000 to establish payment of what is to be known as the Robert W. Hunt Award, \$250 of which will be paid each year for the best paper contributed to the *Proceedings* of the Western Society of Engineers on any subject pertaining to the manufacture or treatment of iron or steel products. The purpose of this award is, in the main, to make membership in the Western Society of Engineers attractive and useful to the younger men of the profession.

The conditions in general which surround the award of this sum are that the member must not be over 30 years of age or a member of the faculty of an educational institution. The decision of the award shall be given to a committee of three, said committee to be annually appointed by the president of the Western Society of Engineers. One member of this committee shall be a man of recognized experience and established reputation in the manufacture of iron or steel. If in order to obtain such a member for the committee it is necessary for the president to go outside of the membership of the Western Society of Engineers, he shall be authorized to do so.

If in the opinion of those upon whom the allotment shall rest there should not have been contributed during the year any paper worthy of the award, the trust company shall pay the year's interest to the proper authorities of St. Luke's Hospital.

An Innovation in Insurance for Chemical Plants

EXPANSION in chemistry is coming into view on every side. The latest addition is the establishment of a department of chemical risks by four associated fire insurance companies, namely, the North British and Mercantile Insurance Co. of New York, the Pennsylvania Fire Insurance Co. of Philadelphia, the Commonwealth Insurance Co. of New York and the Mercantile Insurance Co. of America, also of New York.

For many years it has been the custom among fire underwriters to classify "chemical works" as a group by themselves, and to consider them as abounding in unknown and incalculable hazards, and to write very modest lines of insurance upon them. In view of its status as a key industry and of the economic need of chemical manufacturers for indemnity in the event of loss, the above-mentioned insurance companies appointed W. D. Grier to look into the subject generally, to see how much business there was, and if it would be worth while to establish a special underwriting department to extend service to chemical industries, such as is given to manufacturing concerns under sprinkler protection, with a constant view to decreasing the fire hazards.

The investigation showed a great deal to be done, and these companies organized a special Chemical Department, Mr. Grier being put in charge. It is believed that they are the first to organize such a department, the object of which is to give fire protection engineering service to chemical industries, looking to elimination of unnecessary risks and consequent loss and interruption of manufacture. This is done without charge to parties assured.

Mr. Grier's investigations brought out some of the defects in installation which are found more or less frequently. Among them are the following:

In regard to such inflammable liquids as benzene, etc., the method of storing is always a matter of interest, and so also is the installation of piping, with the risk of a break in the connections and a resulting fire that is mean to handle.

Arrangements for warming tank cars are often defective and dangerous.

There are frequently found defective fuel oil systems and these cause fires.

Apparatus provided with direct heat often have defective furnaces.

Oil baths are often improperly installed and carry considerable risk.

Nitration may be inadequately isolated and defective methods of nitration are occasionally discovered.

The methods of handling highly inflammable or explosive substances need careful study in each case, and the same may be said of the care of intermediates that are of an impermanent nature.

A frequent source of trouble is the defective venting of inflammable fumes.

Many grinding processes involve serious fire hazards.

The storage of finished products should not be in proximity to the hazard of fire by contagion. This would seem to be self-evident, but it is often forgotten, and the greatest risks and the greatest values are often found together. Sometimes a little flash will open a lot of sprinkler heads and wet down goods of large value. This makes a difference between no claim at all, or possibly \$25 or \$50 on the one hand, and \$40,000 or \$50,000 on the other.

Service parts such as washrooms, toilets, baths, clothes lockers, etc., are often the starting place of fires.

Electric wiring systems suffer deterioration from acid or other fumes, and fires result from cross circuits.

In other words, there is an insurance engineering angle of attack that is often otherwise overlooked, and it is the effort of Mr. Grier and his associates to overcome this neglect. Sometimes the best method of meeting the situation is by making the buildings, as in a powder mill, small and scattered, and to provide heavy outside protection to keep the fires confined to a single unit in each case.

The laboratories of the National Board of Fire Underwriters at Chicago have been doing excellent work in this connection for many years, but the managements of these companies are to be congratulated on their progressive spirit. Once upon a time there was stored in Liverpool, as recollection serves, a large quantity of cotton in the ground floor of a warehouse, and a large quantity of nitrate of soda on the floor above, under the roof. The roof leaked, and the merchandise remained in storage a long time. The fire that ensued was a surprise. There are some fire underwriters who would still be surprised at it.

Brass Founding Methods in Germany

Recently a deputation of men connected with the British Brassfounders Association visited German works in the Rhineland, and, according to the *Iron and Coal Trades Review*, have reported that the main advantage the German has is in the smaller variety of articles produced by each manufacturer, namely, greater concentration on output, resulting, of course, in a larger turnover, combined with that careful attention to the details of manufacture which is a characteristic of the German, from the head to the humblest employee.

The casting methods appear to offer the greatest divergence from the English system, and while both hand and machine molding appears to be employed very generally, the following differences may be particularly noticed: It appears to be the common practice in all brass foundries to put the molds in an oven as soon as they are made and leave them there until the next day, such molds being taken from the oven the next morning and poured during the day and the oven again refilled for drying a new lot the following night.

Both pit furnaces and tilting furnaces are used for melting, several bessemer-type tilting furnaces made of iron and lined with brick being noticed, this system avoiding the use of crucibles except as a medium for carrying the metal from the furnace to the molds; in some cases the ladles are of iron. The molds when cored up are placed on top of each other into a pile three or four feet high, and the whole bolted together, after which they are laid on end for pouring in the usual way. It also seems a common practice for the castings to be cut off the runners when cold by means of a sprue cutting machine. In one works where hand molding was in progress, in place of using mallets a heavy metal ball about 7 in. in diameter and weighing nearly 50 lb. was rolled all over the mold in order to compress the sand, and this method would possibly insure more regular pressure for work which does not vary too considerably in height. It was also noticed in several instances that loose locating pegs were inserted in the sand of the mold to assist in the accuracy with which the molds were matched.

The Whole U. S. Patent System in Danger

WHEN the Government Printing Office sets up and prints everything that a Senator or Congressman says when he is talking against time to defeat a desirable bill which will pass if his wind gives out, for the merit of which his own party cannot get the credit, it does seem to be about the most useless typographical establishment in the world. But occasionally its publications are of lively interest, and of these we commend a book entitled "Hearings Before the House of Representatives of the 66th Congress, First Session, on H.R. 5011, H.R. 5012 and H.R. 7010. It covers 320 pages, and every bit of it is interesting.

The system of granting an inventor a 17-yr. monopoly for his invention for a comparatively small fee originated in the United States, and its immediate effects were good. These were not measured by the prosperity of the inventors; they were made manifest in the greatly increased number of useful inventions which were recorded in response to the encouragement provided by the system. This was so marked that all the progressive countries of Europe, save those of Latin origin, adopted methods similar to those of this country. The peculiarity of these methods consists in a careful examination of each invention, more particularly as to its novelty, before the patent right is granted. In Latin countries but little more than a system of registration is in effect. Anybody may register what he claims to be an invention by paying the fee, and then he must establish his rights afterward, if he can. This so-called French method has not been found to work well in regard to real inventions.

Switzerland and Holland tested out the plan of having no patents at all. Both found that without a patent law the incentive to follow up and manufacture new things was lacking, and that progress in this respect declined rather than increased. Later both countries enacted patent laws based on the system in force in America.

THE MERIT OF PATENTS

The merit of patents seems to be due to several related causes. To introduce anything new usually requires time, energy and expense, in which time and energy may also be expressed in terms of expense. Without a monopoly for a given time the inventor or owner of the patent must nevertheless undertake or provide for the cost of introduction, after which any competitor may reap the same benefit as he. Without a patent the inventor is at a disadvantage, because any competitor can reap his reward without paying the price of introduction for it. The premium on novelties takes a precipitous dip as soon as we pass the millinery business, and it becomes a charge as soon as we reach materials and machinery. The lack of a patent system makes invention a liability rather than an asset. On the other hand, when an inventor publishes his invention in a patent he becomes the nation's teacher; he stimulates enterprise and encourages more invention. Fundamental patents are always followed by a large number of applications from new sources relating to improvements in detail. And we must remember that after an invention has been a monopoly for 17 years it becomes the property of the people.

What our Patent Office suffers from is neglect—Congressional neglect. We shall endeavor to show its most pressing requirements.

As soon as the National Research Council found itself it appointed a committee to consider the matter of patents. These gentlemen were William F. Durand, chairman; L. H. Baekeland, acting chairman in Dr. Durand's absence; M. F. Pupin, R. A. Milliken, S. W. Stratton, Reid Hunt, F. P. Fish, ex-Commissioner Thomas Ewing, and Edward J. Prindle. They proposed the three bills under discussion, which are now in the hands of the Committee on Patents. We shall consider their provisions after we have discussed the situation.

SHABBY TREATMENT OF PATENT EXAMINERS

In our issue of Sept. 1 we spoke editorially of "Shabby Treatment of Patent Examiners." In 1848 the salary of each primary or chief examiner was fixed at \$2500, or the same as that of members of Congress. It was held that as the examiners must be men of professional education and training, their habits of life and requirements would be about the same of those of Congressmen. Their responsibilities are very great; a single error may involve millions of dollars in expense, and do incalculable injustice. The cost of dishonesty would also be beyond computation. The salary of these same primary examiners is now \$2700. Since 1848, Congressmen have raised their own salaries from \$2500 to \$7500, and those of principal examiners from \$2500 to \$2700. There are 45 primary examiners, and 360 first, second, third and fourth assistant examiners receiving respectively \$2400, \$2100, \$1800 and \$1500 each per year. The force includes 7 doctors of philosophy, 18 doctors of medicine, 1 doctor of dental surgery, 21 mechanical engineers, 19 electrical engineers, 19 civil engineers, 2 chemical engineers and hundreds having masters' and bachelors' degrees. Few good examiners will remain at these figures, except those that are staying on out of loyalty and love of the work. The Commissioner is required to fill vacancies with temporary appointees, because the Civil Service Commission cannot induce enough good men to try for the positions. So much for salaries. The work is rapidly running behind, and it is falling off in quality. Nevertheless this same corps of examiners is the very key to our entire patent system. Every neglect, every mistake on an important invention invites long, expensive litigation and hinders a poor inventor from obtaining his rights.

ANOMALOUS POSITION OF THE PATENT OFFICE

The Bureau is in charge of the Secretary of the Interior, although it can hardly be said to be under his authority. He represents it, but he does not control it. His approval is required for changes in the rules of practice, but he has no power to compel changes, or to organize improvements. There is nothing in common between the interests of the Interior Department and the Patent Office. Its situation is in the Interior Department, but not of it. The result is the Patent Office is either left out in the cold, or its needs are judged in connection with the requirements, for instance, of the Pension and General Land Office—and this through no fault of the Secretary of the Interior either. The Congressional Mind builds up its own theories.

In regard to patent litigation we have this situation: The calendar of the Supreme Court is so crowded that no patent suits will be considered by it, save in very rare instances. The right of appeal except under a writ of certiorari which involves the willingness of the court to hear the case was taken away in 1891. The final courts of adjudication in patent cases, therefore, are in effect the nine United States Appellate Courts of concurrent jurisdiction. Therefore if either party to a patent suit is dissatisfied with the decision of one of the nine Circuit Courts of Appeal, he may try the suit out again in any one of the eight others, and thus keep up the misery for an insufferably long time. Let us quote from the address of Mr. Frederick P. Fish before the committee. He said: "If either the plaintiff or the defendant in a patent suit loses his case, he says to himself that the particular court in which his case was decided only controls the territory, for instance, of the First Circuit—Maine, New Hampshire, Massachusetts and Rhode Island—and that he may be able to get a different decision in a different part of the country. He has every inclination to try his luck in Ohio or New Jersey or somewhere else, and very frequently when the plaintiff is beaten he will go into another court in another section of the country, and try the case over again. In like manner infringers in other circuits will go on as before, hoping for a different result in a new case against them."

This is an exceedingly unwholesome condition of affairs. It also stands to reason that, with the best of intentions, some judges are quick to understand the points at issue in a patent suit, while others have difficulty in achieving a clear vision of the same problem.

DAMAGES THE LAST THING EXPECTED

Under present conditions when a patent suit is decided and, let us say, infringement is proved to the satisfaction of the court, an injunction is issued. But damages may not be obtained save in very rare instances. Usually it is held that the exact amount of damages must be proved. It is seldom that a patent covers the whole of an article that is sold, so that the plaintiff must figure out and prove the exact sum involved—which of course he can't. And in default of precise figures the usual award is six cents. The law has ways of its own. Recently there have been two or three decisions in which the courts have taken a more liberal attitude and awarded a reasonable royalty, but it is admitted by lawyers that it will take a whole generation to induce the United States courts to adopt this position generally, unless special provision is made for it by legislation. As things are, about the last thing a plaintiff in a patent suit expects to get is damages.

THE LEGISLATION PROPOSED

The proposed legislation remedies all these features. It provides for a new court of seven members to sit in Washington. The Chief Justice is to be appointed for life by the President, thus giving to the court an element of continuity. The other judges are to be selected by the Chief Justice of the United States from the various District and Circuit Judges throughout the land, and are to serve for six years each, three to be appointed every three years. This would assure the appointment of judges who had experience in patent litigation, but their rotation in office would avoid the like-

lihood that the court become narrow in its views, owing to the nature of its work. It would also provide that the judges come from various communities, and thus the charge that any special interests might have had a hand in the appointment would be avoided. They are to be adequately paid, the Chief Justice at the rate of \$12,000 a year, and the Associate Justices \$11,500 each. The establishment of a Court of Patent Appeals has been advocated by the American Bar Association for many years. It would put backbone and dignity into our patent system.

Another bill increases the salaries of members of the Patent Office staff so that, for instance, principal examiners now getting \$2700 will receive \$4000, and the first, second, third and fourth assistants respectively \$3300, \$2700, \$2200 and \$1800 each. Other salaries are in proportion and are no more than commensurate with those paid in other and unforgotten departments of the Government. Other countries—Great Britain and Holland, as was brought out in the hearings—pay their examiners and staff much better than we do.

Another bill makes the office an independent bureau, and provides also that "If proof is not offered, or in the absence of adequate proof of the amount that should be awarded as damages or profits, the court, on due proceedings had, may adjudge and decree to the owner, payment of a reasonable royalty or other form of damages." In other words, it substitutes a reasonable royalty for six cents.

Every feature of these bills is of prime importance, and is of interest to the people as a whole. Under our present defective system it usually takes from six to eight years to find out whether an important patent is valid or not. Under the proposed changes, one and a half years should be the maximum time, save in extraordinary cases. Under present conditions, unless a man has vast wealth back of him he cannot afford patent litigation against a rich offender. That is a situation so radically wrong and so contrary to the temper of the times that it is not even the part of good citizenship to endure it.

PEOPLE SHOULD AWAKE TO THE SITUATION

Many persons refuse to take the trouble to read anything about patents on the ground that they are not interested. But that is a fault of neglect. It isn't so much that inventors need to be protected; it is an unfair situation that has come into being because of Congressional neglect that threatens the peace and general welfare. The present uncertainty and expense of maintaining a patent are very costly, and the money to pay for it in the end comes out of the pockets of the public—and swells the cost of living. Patent business is everybody's business for this reason, and because it encourages invention. Therefore we have no right to sit still and twirl our thumbs while one of our important and needed institutions goes to seed—and sows dragon's teeth in the process.

It is generally admitted by men of experience in Washington that the best way to reach the Congressional Mind is to write from a Congressman's district to him. If we can induce our readers to write to their representatives in Congress urging them to support the bills mentioned, H.R. 5011, H.R. 5012 and H.R. 7010, we believe we shall have contributed an important service.

The Forest Products Laboratory

A Government Institution Serving the Public Both Directly and Through Valuable Data Furnished to Engineers, Architects and Industrial Concerns—Research in Methods of Mechanical Application and Chemical Derivatives of Forest Growths

By CHESTER H. JONES

THE Forest Service of the United States Department of Agriculture maintains the Forest Products Laboratory, located at Madison, Wisconsin, and operating on industrial research in all applications and uses for products of the forest. Funds for the support of this work are at present appropriated by the Department of Agriculture and the Army and Navy Ordnance and Air Services. The University of Wisconsin furnishes the buildings (Fig. 1), together with heat, light and power. The officials and operators are all on the Government payroll.

The facilities are at the service of any individual or firm that wishes to use them. Contact with the industries and public is continued through personal visits to Madison, correspondence, official publications, and articles appearing in the periodical press. The laboratory is open to visitors, both those who have a general interest and those who wish to spend some time in working out specific problems. Every effort is made to give full and complete answers to inquiries made by correspondence.

Any one may request that his name be placed upon the mailing list to receive future publications on special subjects as they are issued. The Superintendent of Documents, Government Printing Office, Washington, D. C., distributes "Price List 43, Forestry," which covers all publications of the laboratory. The bulletins are to be had free at Madison until the supply at hand has been exhausted. About once a month the laboratory issues mimeographed sheets called "Technical Notes." These are brief summaries of the recent work, written especially for the busy man who is interested in results.

IMPORTANCE OF FOREST RESEARCH

A great deal has been written in the technical and popular press about the importance of our forestry problems, and we have all been impressed in a general sort of way. In order really to appreciate the value of research in forest products to the industries dependent upon them and consequently to our universal welfare it is necessary only to witness the work in progress at the Madison laboratory. The visitor becomes impressed with the thought that there can scarcely be an individual Government organization whose work is of more worth to our commercial life.

In a recent article¹ reference is made to the subject in part as follows:

"With a total annual cut of 40,000,000,000 ft. board measure of merchantable lumber, another 70,000,000,000 ft. is wasted in the field and at the mill. In the yellow pine belt the values in rosin, turpentine, ethyl alcohol, pine oil, tar, charcoal, and paper stock lost in the waste are three or four times the value of the lumber

produced. Enough yellow pine pulp-wood is consumed in burners or left to rot to make double the total tonnage of paper produced in the United States. Meanwhile, our paper-makers memorialize the community on the scarcity of paper stock, and pay \$18 a cord for pulp-wood which they might buy for \$3 a cord."

With such quantities as this in mind it can easily be seen that each small finding of the laboratory may be great and far reaching in ultimate commercial result.

CO-OPERATIVE WORK

It is the policy of the Forest Service to obtain to as large an extent as practicable the co-operation of the wood-using industries most directly concerned with the subjects or problems under investigation. The exact terms of this co-operation are determined in each specific case. The investigation of a subject is generally not regarded as complete until results obtained experimentally are checked on a commercial scale to determine the industrial application. When this has been done, further co-operation covering the same ground is not entered into.

The laboratory will furnish such general advice and assistance to any one interested as are available in the files covering previous work, such as design, construction and operation of commercial plants for wood preservation, distillation, kiln drying, etc. In some cases approximate costs and suggested plans and specifications may be given. The laboratory may examine methods in existing plants and recommend improvements.

In cases of active co-operation, a remuneration to the Service is expected, equivalent to the total cost of the work done for the co-operator, including both time and expense of members of the laboratory organization detailed on the project. Such remuneration may be reduced by the extent to which the work is strictly experimental and of value to the Service rather than to the co-operator. When practically all the work proposed is investigative, the laboratory having little or no expert knowledge on the subject to begin with, and the results will be of value chiefly to the general public, the charge to the applicant may be comparatively low or eliminated altogether.

As far as practicable co-operative projects will be covered by written agreements. Such agreements are required whenever co-operative investigations of a specific character are to be continued over a period beyond six months or at a cost to the laboratory of over \$100.

Reference to the chart (Fig. 2) will give a clear idea of the organization of the Service, and the type of research work done by the laboratory is shown under "Technical Industrial Research Problems." The views in Fig. 1 show the buildings employed to house the operations. The main building contains the general busi-

¹"Developing the Estate," by Arthur D. Little, *Atlantic Monthly*, March, 1919.

ness offices, the chemical and physical laboratories, the paper plant, the glue laboratory, the wood distillation and preservation laboratories, and several of the drying kilns. A comprehensive exhibit embracing nearly every wood specimen known, together with the library and files, is also in this building. The files contain complete records of the work, and "Technical Notes" is issued by an editorial staff.

The yard has the lumber stock, drying kilns, and small buildings where additional operations are in progress. Among these are the box-testing laboratory, the pulp-wood digesters, the fire-proofing test house, etc.

The other buildings shown are occupied by a large amount of equipment and machinery for carrying out the mechanical tests on various woods, and for the manufacture of propellers and structural parts for airplanes. The latter work became highly developed during the war period and will be continued for the Army and Navy Air Services.

The whole aim of the Forest Products Laboratory effort is to promote economy and efficiency in the utiliza-

tion of wood and in the processes by which forest materials are converted into commercial products.

PULP AND PAPER

The laboratory is very well equipped for research in the field of pulp and paper. A complete experimental paper mill with Fourdrinier and cylinder wet ends, two presses, nine drying rolls and a calendar stacker produces paper up to 12 in. in width. Necessary paper-testing apparatus is available in a room where the atmosphere is regulated by a small Carrier Engineering Corporation machine. The digester house is arranged with apparatus for sulphite and sulphate pulp. Fig. 3 shows tumbling soda and sulphate digester in which coniferous woods are converted into wood cellulose for nitration purposes without need of additional purification. Sulphite wood cellulose is also purified in this digester. Fig. 4 shows the upper portion of the sulphite digester with the liquor tank on the left and, on the extreme right, the vat for receiving pulp blown from digester.

FIG. 1. THE FOREST PRODUCTS LABORATORY

Upper Left—Receiving and storage yard. Upper Right—Where airplane parts are tested. Center—Main building. Lower left—Where the mechanical properties of woods are determined. Lower Right—Building used for experimental propeller manufacture.

FIG. 2. ORGANIZATION OF THE FOREST PRODUCTS LABORATORY SERVICE

FIG. 3. SODA AND SULPHATE DIGESTER

The problem of lining an experimental digester is different in many respects from lining problems in the commercial sizes, the most important difference being due to the size. Other differences arise from the fact that in order to obtain quantitative yields, the experimental digester must be washed free from pulp immediately after each blow, and a lining which spalls off and produces a dirty pulp is unsatisfactory. It is out of the question to riffle the pulp and obtain reliable yields.

Many different kinds of linings were installed before a satisfactory one was found. Because of difficulties due to size, tiling similar to that used in larger sizes could not be used. Lead was first tried, but was soon discarded on account of the "creeping" action when subjected to temperature variations. Bronze produced dirty pulp. A solid lining of litharge and glycerine lasted only a short time. Then cement briquets were made of many mixtures, given different coatings, and subjected to the action of sulphite cooking acid. The results of these experiments led to the installation of a lining of 1 to 1 cement and crushed quartz sand, 3 in. thick and coated with sodium silicate. This held up fairly well for some time, though particles of sand were constantly falling off and causing dirty pulp.

It was finally decided to install a solid stoneware casting of acid-proof tile $1\frac{1}{2}$ in. thick. This offered no difficulties of construction, as the digester is joined in the middle. Liberal tolerances were allowed in all dimensions, and openings difficult to locate were left out in the casting, being chiseled out after the casting was in place and backed by cement. This lining proved to be exceedingly satisfactory.

FUTURE WORK ON PULP AND PAPER

The work of this section completed to date covers the valuation of fifty specimens of American woods for chemical pulp and twenty-five for mechanical pulp; the manufacture of Kraft paper from native woods which can compete with imported pulp; the manufacture of

roofing felt from spent hemlock bark; the reduction of 15 per cent waste in the making of ground wood pulp; the reduction of 30 per cent in steam used and 20 per cent increase in density of black liquors in the sulphate and soda processes; the development of a reliable method for determining the tearing strength of paper; the invention of a recording density hydrometer for use in control of soda recovery; and the production of tannin from waste hemlock bark at paper mills.

The future work under consideration will cover the development of standard methods for the purchase of pulp-wood and other raw materials, and their commercial adoption; study of problems in the recovery of waste from the chemical processes, and the use of black liquors, waste sulphite liquors and similar by-products; continuation of work on lumbering wastes and additional species of American woods for pulp and paper; and co-operation with the pulp mills in working out the application on a mill scale of improvements in processes and methods suggested by experience.

Extension of the use of wood-pulp is also under way. This involves the suitability of the species in the manufacture of twine, artificial silk, rugs and textiles, fiber packing containers, articles molded from mixture of asphaltum and pulp, nitrocellulose, gas mask filters, and many other applications.

PRESERVATION—GLUE AND PLYWOOD

One of the most valuable developments in this department is the manufacture of glue and plywood. The glue is a factor nearly as important as the wood itself, because the finished product is directly dependent for its efficiency on the quality of the glue used in its construction. The uses for plywood are unlimited and its increasing employment in the industries operates directly in the conservation of wood wastes.

FIG. 4. SULPHITE DIGESTER

It is expected that the next few years will see a marked increase, not only in the use of plywood but in its form of manufacture and its application to various uses. The laboratory has developed new economical and practical manufacturing methods and standard tests to secure uniformity of product, and has determined the suitability of woods heretofore unused for plywood.

Work is yet to be done along these lines and the results will be the basis for the intelligent use of plywood. It has even been predicted that there will be upon the market within a few years houses of the "ready-built" design made almost entirely of plywood construction.

The research work on glues consists of the development and improvement of water-resistant glues, study

the specially adapted Riehle cement briquet testing machine as shown in Fig. 6. The jaws were made in the laboratory shops. The strength of a glued joint depends not only on the chemical and physical qualities of the glue but also on the pressure exerted in the veneer press when the joint is setting. Either an excess or a lack of pressure weakens the joint. Standard formulae have been worked out for this feature.

The data available from experiments completed cover a wide range of valuable information. Specifications have been made for glues purchased by the Army and Navy Departments, together with standard analyses. Moisture-proof coatings have also been developed.

Future research on plywood will include shrinkage factors for plywood of different species, accurate information as to strength and design of nail, screw and other fastenings for plywood, studies of warping and effect of vibration on plywood, effects of high temperatures on strength, absorption of moisture under varying humidity and effect on strength, and study of special adaptations in the industry.

PRESERVING WOOD

Losses due to decay of timber used in construction, poles, posts, piling, ties, etc., reach a high figure annually. Considerable work has been done to prevent this. Fig. 7 shows the equipment used in the labora-

FIG. 5. FOAMING TEST FOR ANIMAL GLUES

of commercial glues, analyses and specifications for glue components, glue strength and durability tests, plywood manufacturing problems, and instruction of industrial representatives.

Future activities in glues will embrace studies of glue and plywood manufacture, with reference to particular uses in various industries, improvements in quality and lowering costs of water-resistant glues, development of wide industrial use of waterproof glues, adaptation to furniture and vehicle manufacture, and assistance to makers of glued products in their special problems.

An article on "Water-Resistant Glues" by F. L. Browne of the laboratory was published in *CHEMICAL & METALLURGICAL ENGINEERING*, Aug. 1, 1919, in which the work was covered in considerable detail. The glues are mixed in an ordinary 3-speed dough mixer as described, and are tested in several ways. The standard test for tendency of glue to foam is shown in Fig. 5, the glue being stirred mechanically in a glass of standard size. The amount of foam formed is measured after a given time, and also the time consumed in subsiding is noted. Glue which foams badly may give unsatisfactory joints.

After the glue is applied and set in a plywood specimen, test of shearing strength of glued joints is made in

FIG. 6. RIEHLE MACHINE FOR TESTING GLUED JOINTS

tory for the pressure treatment of wood for both preservation against decay and fire-resistant compounds.

The new work in this section will involve a study of preservatives to improve those now in use; new preservatives for salt water piling; improvements in preservative manufacture; determinations of wood penetration by preservatives to obtain better methods of treatment; an investigation of the fundamental prin-

FIG. 7. WOOD IMPREGNATING RETORTS

ciples of decay and of the causes of deterioration of wood in buildings; and studies in fire protection both by changes in construction and fire-retardant compounds.

PACKING CONTAINERS

While the work of this section does not depend on the chemical laboratory for its results, nevertheless the Department of Timber Mechanics has discovered things of vital interest to shippers of chemicals and allied products. These results of box laboratory tests have demonstrated methods of saving large sums annually in freight, damage to goods en route, and conservation of lumber, to all shippers using crates or boxes. Previous to the starting of tests for the Army Ordnance Department no adequate method of testing a container had been devised. The work is being carried on in close co-operation with the box associations and the Railroad Administration in order to obtain data of the greatest value.

The properly designed packing box should first of all be balanced in construction, that is, have enough strength in each part to serve the purpose and no more than is necessary to equal the average strength of the entire box. The data obviously could not be collected from actual service conditions, as the destruction would not be witnessed in sufficient detail, so it was necessary to devise methods of test which would approximate serv-

ice conditions and combine practical experience in box design with these tests.

The compression-along-the-edge test is a steady and constantly increasing pressure (measured in pounds) applied along any edge with an opposite edge diagonally through the box in direct line with the pressure exerted. The cornerwise test is applied through diagonally opposite corners in the same manner. These two tests measure the resistance of a box to external pressure, but are insufficient to determine weaknesses and balanced construction. In comparing one box with an-

FIG. 9. SMALL BOX TESTING MACHINE

other the drop test is of value. This consists of dropping a box on one corner from a specified height when loaded with contents. All these tests, however, are very much limited.

The new method consists of placing the box with contents in a hexagonal drum and slowly revolving the drum until the box is broken. Within this drum a regular cycle of drops of the box is arranged so it falls upon sides, top, bottom, ends, edges, corners and flatwise upon steel studs similar to corners of another box. This gives all the conditions of actual service except heavy pressure received in lower tiers of a pile. This is determined by the compression-on-edge test hitherto mentioned.

During the time the box is revolving in the drum each weak feature may be noted as it develops. Nails may pull out, material may split, and the observer, by repeated experiments, will eventually arrive at a box that is equally strong in every feature. Such defects in the wood as affect the proper efficiency of the container must be eliminated, but others not harmful to the balancing of strength should be allowed to remain, to keep down the cost of manufacturing.

Fig. 8 shows a part of the large machine used. It is about 18 ft. in diameter, with a hexagonal interior. The operator views the interior from the switch shown on the post or from the platform shown overhead. Fig. 9 shows the smaller machine in operation. The factory

FIG. 8. LARGE BOX TESTING MACHINE

of every box-maker should contain one of these machines, for this method of "proof of the package" overshadows all the crude tests heretofore employed.

It discovers the size, quality and shape of lumber needed. It proves the kind, size and spacing of nails, the quality, size and location of metal strapping, the type of handle best employed, and all the special features required for the article to be packed.

The majority of the containers tested have been proved 15 to 20 per cent too heavy and occupied a like amount of excess space. Fig. 10 illustrates a crate designed to supersede a heavy box and employing the three-way corner construction. For foreign shipment of ordnance material the redesign of a box to carry thirty 1-lb. cans of saddle soap saved 43 per cent in cargo space. A redesigned cannon powder box carrying 140 lb. of powder saved 14 per cent space. Twenty-eight per cent of space was saved on a box for two Browning automatic machine guns, and 33 per cent on one for ten rifles. Official reports from France show that the broken package loss was only 15 per cent of that formerly occurring, which compares favorably with domestic shipments.

The future field for container research at the laboratory is at once seen to be large. The lines laid down for new work call for a determination of the best methods of box and crate construction; study of fiber and corrugated container design; design of barrels and baskets; finding the relation between weight of contents and thickness of material; preparation of specifications for domestic and export boxes; application of various types of strapping; study of holding power of nails; designs to use up short lengths of lumber; and a comprehensive study of records of loss and damage to shipping containers and methods of overcoming present losses.

Other work in timber mechanics has been extensive operations in airplane design. One feature of interest is the bending of heavy stock for artillery wheels as shown in Fig. 11. Many machines located throughout the laboratory are used for mechanical tests. Built-up sections of airplane beams, struts, ribs and operating parts are in the course of construction. These pieces

FIG. 11. BENDING WHEEL STOCK

show some valuable examples of wood fabrication for general application, and structural designers in the chemical industries may study them with profit.

Even a brief view of the operations is an education in mechanical design involving the use of timbers. Exhaustive tests are conducted on plywood and glued joints as well as those of specific articles of manufacture. Information furnished by this department is of great value to engineers, architects and manufacturers.

TIMBER PHYSICS

The dry kiln section renders service to all industries through the improvement in mechanical resistance of kiln-dried wood as compared to green timber. The majority of kilns in use are patterned after the Forest Products Laboratory kiln. It is hoped that the consumers of wood will ultimately see the advantage of using a kiln-dried product for all purposes.

The kiln consists of a brick-walled rectangular structure, heated within by steam coils. In addition to the steam piping a series of water sprays, located along the sides, furnish an air draught throughout the interior, at the same time giving the proper humidity to the atmosphere. The control of both temperature and humidity is entirely automatic.

The future work on drying will involve a continuation of studies on the effect of drying on additional species; requirements for the greatest strength and reduction in drying time; extension of exact information concerning the proper methods of certain refractory species like swamp oaks, the value of which is limited by seasoning difficulties; reduction of working formulae to simplest terms when dealing with raw wood; and the making more accessible to manufacturers of lumber, vehicles, aircraft, freight cars, furniture, and interior finish, the basic data that have been evolved.

Additional work on kiln design proper will embrace the determination of types best suited to different kinds of work; perfection of kilns capable of accurate control at least cost; extension of basic information on improvement of commercial kilns now in use; investigation of various types now on the market; and supplying data to the industry for installation of better kilns.

The division on Derived Products is of the greatest interest to those who think in ways chemical, and while

FIG. 10. ECONOMICALLY DESIGNED CRATE

not so active as others at the present time, due mainly to the markets, it will nevertheless entertain CHEMICAL & METALLURGICAL ENGINEERING readers with its possibilities. Derived products, as in many other branches of the chemical industry, can be made from parts which would otherwise be wasted, a fact truly delightful to contemplate in these days when so many savings are made through the aptly called by-products.

Complete apparatus is installed for study in connection with wood distillation. Hardwoods previously thought unfit have been found available, causing the installation of new plants throughout the country. A method of controlling temperature of distillation has been developed which increases the production of calcium acetate 8 to 12 per cent and of wood alcohol 5 to 10 per cent. Tar still control has been improved, effect of wood moisture has been studied and new tar products for high-grade flotation oils have been discovered. The pine oils have become standards in the concentration of sulphide ores.

The cup and gutter system of turpentine orcharding developed by research is an example of the improvement in production of naval stores. Acetic and acetone work for airplane dope, gas mask charcoal from wood, carbon monoxide absorbent for gas masks, and the production of tear gases, poison gases and munition chem-

commercial value. Cinnamic acid and cinnamic alcohol are two of its valuable components.

Future investigations are contemplated in production efficiency and uses of turpentine, rosin, grain alcohol, acetic acid and charcoal; studies will be made to develop practical processes of value concerned with comparative yields of wood, increasing yields of valuable products and improved methods of refining products; classification of methods applied to wood species and quality, and value of products will be sought; the production and new uses of tar oils will be developed.

ADDITIONAL FUTURE RESEARCH

Although the large amount of effort put forth under high pressure during the period just past has given a wonderful impetus to forest products investigations as well as operations in the field on a commercial scale, the interest should be maintained. An extensive program of work is planned in addition to that covered here.

Industrial strength requirements have been demonstrated through present limited knowledge to be important. Determinations of the fundamental laws governing the strength of wooden columns, of the strengths of different wood species for use in telephone poles, etc., of definite factors of safety for beams under continuous loads, of efficiency of joints and fastenings in wooden structures, and conditions where low-grade woods may be used are all of commercial interest. Data must be obtained on use of wood for rebuilding railway cars, and also comparative data on strengths of commercial woods.

General lumber study will be developed to obtain data for cost accounting and timber appraisal, to obtain information on woods of the United States suitable for export, to determine new uses and markets for lumber as made possible through the development of plywood, built-up construction, etc., and to solve economic problems of lumber supply and distribution of finished products. The field work calls for liaison with lumber manufacturers, veneer and panel makers, vehicle and implement manufacturers, box makers, shippers, pulp and paper industry, turpentine, rosin and glue producers, dairymen, leather and tanning industries, railroads, engineers, architects and technical professions, fire underwriters, chemical industries, and others dependent on wood products.

PRACTICAL RESULTS OF THE FOREST PRODUCTS LABORATORY WORK

The years occupied in research by the Forest Service have borne fruit in the production of a large amount of data of general service to many industries and individuals, and copies of results may be had for the asking. The range of effort is so wide and the ramifications of the work so far reaching that it has been possible to mention only a few features in this article, with the hope of arousing the interest of those who may not be familiar with the more active phases, thereby bringing them in touch with the laboratory to the ultimate benefit of the industry.

The net gain in wealth to the nation through the activities of the Forest Products Laboratory is so great that adequate funds from general taxation should be always available for its financial support.

We are indebted to Mr. Rolf Thelen, acting director, for information making possible the preparation of this article.

FIG. 12. ETHYL ALCOHOL FROM WOOD AND
SULPHITE LIQUOR

icals have all contributed to the utilization of wood wastes during the war. An oil-jacketed still for operation under constant temperature is used largely in distillation tests.

In spite of the fact that we no longer are permitted to absorb ethyl alcohol directly, it nevertheless has an increasing use in pharmaceutical and cosmetic preparations. The laboratory has installed a complete plant for the production of ethyl alcohol from wood and sulphite waste liquors, shown in Fig. 12. The wood cellulose is converted into fermentable sugars by treatment with acid.

Other products derived from the forest growths are tannins, essential oils from bark and leaves and wood producer gas. Chemical derivatives from cellulose are also susceptible to development. A gum which is in demand by manufacturers of perfumes, tobacco, adhesives and drugs is produced from the red gum tree of the Southern States, though few owners realize its

Resistance of Absorption Tower Packing to Gas Flow*

BY FRED C. ZEISBERG

THE past few years have seen an enormous increase in the manufacture of various types of tower packing, and several patents have been taken out on designs developed by various inventors and manufacturers of chemical pottery. Acid manufacturers have been quick to recognize the advantages possessed by these manufactured packings, and have largely replaced the pumice, quartz or coke formerly used, with rings, blocks, and other shapes. While an improvement in absorption has nearly always accompanied the adoption of one of these modern packing materials, no numerical method of expressing this advantage has been available except the figures on surface and free space, quoted by the manufacturer of the packing, and these are frequently erroneous.

For this reason the E. I. duPont de Nemours & Co. undertook a study of various types of tower packing, with the purpose of checking up definitely the surface and free space figures not only of the artificial packings, but also of quartz and coke, and more important still, to investigate the resistance to gas flow offered by the various types of packing in common use. In large absorption systems the resistance is an important consideration, since if improperly designed, the system will require excessive pressures to bring about the necessary gas flow. It was hoped that the data obtained would stimulate packing manufacturers to produce newer and still better types of packing.

The projected study was mentioned to Mr. Hood, of the B. Millin Hood Brick Co., and he very kindly offered to donate such of his products as we might wish to test. His offer was accepted and the following packing material was furnished by him: 3 x 3 in. corrugated diaphragm rings, 3 x 3 in. corrugated spiral rings, 6 x 6 in. corrugated spiral rings, 6 in. Hechenbleikner blocks and 1½ x 4 x 8 in. chemical ware tile. The General Ceramics Co. also loaned us a supply of 1-in. Raschig rings.

Figures for the surface of the packing materials were

*Read at the Savannah meeting of the American Institute of Chemical Engineers, Dec. 3-6, 1919.

calculated from measurements, and are expressed as "square feet per cubic foot." Since many of the British journals express this figure as "square yards per cubic yard" and the French and German journals as "square meters per cubic meter," it may be desirable to point out here that all of these values are of a different magnitude. One square foot per cubic foot is equivalent to 3 square yards per cubic yard or 3.28 square meters per cubic meter. With quartz and coke, of course, the measurements are approximate only, and consequently surface figures for these materials do not possess the accuracy of those for the manufactured packings. It might be well, also, to point out that in the case of the manufactured corrugated packings the assumption was made that the corrugations did not add anything to the surface, which is not strictly true.

FRICTIONAL RESISTANCE TO GAS FLOW

The free space of a packing is the interstitial space. It is the space through which the gas must pass and is expressed as a percentage. Thus, a free space of 50 per cent means that in 100 cu.ft. of packing material 50 cu.ft. of gas passages exist. The free space herein reported was obtained by taking into consideration the number of pieces of packing required to fill a known volume, together with the average weight per piece and the apparent specific gravity of the packing material, or by actually weighing the amount of packing material whose apparent specific gravity was known which was required to fill a known volume. The free space naturally varies with the type of packing and with the manner of disposing it in the tower.

The resistance offered by a tower packing to gas flow is of course dependent upon both the free space and the surface exposed, but just what effect each might have it is impossible to predict. For this reason air was actually blown through a variety of packings under various conditions and the resistance was actually measured.

Experimental equipment consisted of a Wilbraham Green positive-pressure blower connected with a series of chemical ware absorption towers 30 in. in diameter and approximately 15 ft. high. The air passed into the bottom of each tower in succession, being carried from the top of one tower to the bottom of the tower

TABLE 1—CHARACTERISTICS OF VARIOUS TOWER PACKINGS

* Wet with 92 per cent sulphuric acid instead of water. (1) dumped. (2) stacked. (3) packed.

following by an 8-in. pipe. A valved side connection in the pipe to the first tower was provided, so that the amount of air passing into the tower could be regulated by spilling the excess to the atmosphere. The air passing into the tower was measured with a glass Pitot tube of the American Blower Co. type, while differential manometers, protected from velocity pressure effects, were provided at the bottom and top of each tower to measure the static pressures at those points. A carefully measured height of the packing to be tested was supported on a checkered brick pier in the bottom of the tower. The resistance offered by this pier to an air flow much larger than is ever likely to be met in practice was actually determined to be negligible. In some cases a series of measurements was made simultaneously in several towers, but since the results thus determined were found to be in good agreement the later tests were run on only one tower.

DERIVATION OF CONSTANTS

Since the constants which are shown in Table I, together with other characteristics of various types of packing, will be unintelligible without explanation, it is desirable at this point to give some attention to the theoretical considerations involved.

Assuming that the general law of the flow of fluids holds in this case (this was experimentally demonstrated to be true), the frictional resistance is proportional to the square of the velocity of flow. This resistance may be expressed as the pressure necessary to produce the given flow.

Let s = linear velocity in ft. per. min.

p = pressure in inches of water

k = a fractional constant

a = area of cross section of packing in sq.ft.

h = height of packing in ft.

v = volume of air passing in cu.ft. per min.

$$\text{Then } p = \frac{ks^2}{v} \quad (1)$$

$$\text{and } s = a \quad (2)$$

$$\text{Therefore } p = \frac{kv^2}{a^2} \quad (3)$$

Since the resistance or the pressure varies directly as the height of the packing we may write

$$p = \frac{khv^2}{a^2} \quad (4)$$

However, k is a general constant, varying in value with the type of packing. We have therefore designated f as the frictional coefficient of 1 sq.ft. of packing 1 ft. high, and may write equation (4) as

$$p = \frac{fhv^2}{a^2} \quad (5)$$

f of course differs for each style of packing, with its method of disposal in the tower and with the amount of liquid circulating in the tower. In order to make f more descriptive, subscripts have been added, as follows:

f_d = packing dumped into tower

f_s = packing stacked, i. e., arranged regularly in layers, but with no attempt to have pieces in one layer in any way related to those in adjacent layers.

f_p = packing packed, i. e., arranged regularly in layers, with the axes of pieces in adjacent layers coinciding.

f_y = packing dry.

f_w = packing wet with water, but drained as completely as possible.

f_c = packing with water circulating over it at a rate of 11 lb. per sq.ft. cross sectional area per min.

It is, of course, evident that we may have, for example, f_{dy} = packing dumped and dry, and that quartz or coke can give values only for f_d and not for f_p or f_s .

The frictional coefficient was then determined for various packings under various conditions, by measuring the pressure drop through a tower filled to a known height with the packing and calculating this value to the standard condition of a 1-ft. cube. These values of f , together with other characteristic data, are given in tabular form in Table I. It should be emphasized that the frictional coefficient values are not accurate to more than two significant figures, and in some cases the second figure is in some doubt.

VARIATION OF RESISTANCE WITH PACKING SIZES

These figures speak for themselves; nevertheless, a few of the more obvious facts will be pointed out. For instance, it is interesting to note how rapidly the resistance to gas flow increases with decrease in size of material (see quartz). That this resistance is not entirely a function of the surface exposed by the packing is indicated by the fact that as the size decreases the resistance increases first less rapidly than the surface and then considerably more rapidly. Another interesting fact is the increase in resistance, with the smaller packings, due to a mere wetting of the packing. Often the difference in resistance between a dry and a wet packing is greater than the difference between a merely wet packing and the same packing with considerable water circulating over it.

Perhaps the most noticeable thing brought out by Table I is the fact that for a given size of packing the manufactured packings give much more surface and greater free space and interpose much less resistance in the absorption system than quartz, coke or packings of that kind. Many other points will be obvious to the reader.

PROBLEM AND SOLUTION BY USE OF CONSTANTS

An example of the application of the resistance constants may not be amiss. Suppose it is desired to find out what pressure will be necessary to force 250 cu.ft. of air per minute through an absorption system composed of 5 towers 2 ft. in diameter and filled 10 ft. deep with absorption material, when 3-in. quartz is used or when 3-in. spiral rings, stacked, are used, the rate of water circulation being 5 lb. per sq.ft. cross sectional area per minute.

The cross sectional area of the packing is $\frac{\pi 2^2}{4} = 3.14$ sq.ft. The total height is $5 \times 10 = 50$ ft. For quartz f_{dy} would be about $120 \times 10^{-7} = 0.000012$, and for spiral rings about $58 \times 10^{-7} = 0.000058$ (since the rate of circulation for f_c in Table I was 11 lb. per sq.ft. per min., values are assumed about halfway between f_w and f_c).

We have seen from equation (5) that the pressure is $p = \frac{fhv^2}{a^2}$, or, substituting numerical values for f, h, v, d ,

$$p = \frac{0.000012 \times 50 \times (250)^2}{(3.14)^2} = \frac{0.000012 \times 50 \times 62500}{9.88}$$

$$\frac{37.5}{9.88} = 3.8 \text{ in. water for quartz. For spiral rings the pressure would be } 3.8 \times \frac{0.0000058}{0.000012} = 1.8 \text{ in.}$$

In closing this paper the writer wishes, first, to thank E. I. duPont de Nemours & Co. for permission to publish these results, and, second, to acknowledge the great assistance of Dr. Guy B. Taylor in obtaining the figures, the actual carrying on of the experimental work being in his hands.

Use of Rosin in Paint and Varnish*

BY MAXIMILIAN TOCH

AS FAR back as any man in the paint and varnish industry can remember, rosin has not only been despised, but its general use has been discouraged by paint chemists, and endless numbers of tests have been devised so that as a paint and varnish material its use has been discouraged. In addition to that, manufacturers have always been more or less ashamed to acknowledge that they have used it; and, so far as I am personally concerned, I have never been a believer in it, excepting for the manufacture of resinates as driers, because up to within a few years ago no rosin varnish or paint oil containing rosin had been made which had much merit. Up to 1914 there was hardly a specification that I know of that did not read similar to the following one which I quote.

CABINET RUBBING VARNISH

Composition—To be made exclusively from the best grade of hard varnish resins, pure linseed oil, pure spirits of turpentine, and lead manganese driers, and be free from all adulterants or other foreign materials.

PAINT DRIER

Composition—To be composed of lead, manganese, or cobalt, or a mixture of any of these elements, combined with pure linseed oil and hydrocarbon solvent, and to be free from adulterants, sediment, and suspended matter. Resins other than rosin may also be used at the option of the manufacturer.

JAPAN DRIER

To be made of varnish gums, linseed oil, turpentine and lead and manganese driers. Common rosin, benzine and similar adulterants must be absent.

SPAR VARNISH

Composition and Quality—Spar varnish shall be made exclusively from the best grade of hard varnish resins, pure linseed oil, pure spirits of turpentine and lead-manganese or cobalt driers, and shall be free from all adulterants or other foreign materials.

It is not my intention to go deeply into the chemistry of rosin, because the material is well known and has specific characteristics. Suffice it to say that rosin is obtained from the sap of certain species of pine trees. This sap is collected by scarifying the tree and collecting the sap, which solidifies under the name of "gum thus." When this "gum thus," which is a yellow, viscous, semi-hard and waxy looking material, is distilled, it yields turpentine by condensation and rosin remains behind.

Rosin is a brittle, soft resin, which ranges in color from a pale yellow glass-like looking substance to a very dark brown, almost black solid. It melts very readily

and is practically fluid at the temperature of boiling water. Under ordinary circumstances, when converted into a paint oil or into a varnish, it turns white and becomes friable when subjected to even slight moisture and rubs off very readily when even slight friction is applied. It is so highly acid that lead and zinc, or other basic pigments, cannot be mixed with it, for it forms resinates so rapidly that the resulting material "livers," or becomes semi-solid or gelatinous before it can be entirely applied or consumed. It does not stand water, and when used as a furniture varnish it becomes soft and sticky on a rainy day; and, all in all, it has been regarded as a totally unfit material for paint or varnish purposes. Yet, the great reason for its use has been that there is nothing like it so low in price, and consequently it was a ready adulterant for the higher priced and better resins.

A TYPICAL CASE

Speaking again of the specifications which prohibited its use, I recall a case some years ago where a manufacturer furnished under a Government specification a large quantity of spar varnish for boat use, and the specification read that the varnish was to be composed of fossil or semi-fossil resins reduced with linseed oil and a proper solvent and drier. The varnish was delivered and was rejected, because it gave the Liebermann-Storch color reaction for rosin.

The manufacturer contended that he did not put rosin in the varnish as an adulterant, and the Government claimed that the specifications had been violated; and, in order to settle this matter and prevent a law-suit, the Government selected me as an arbitrator and the manufacturer did the same. On investigation, I found that a very small percentage of rosin had been used to "grease the kettle" in order to prevent the discoloration of the fossil resin by melting, and I therefore decided in favor of the manufacturer. But this, and many other examples that I could cite, indicate that rosin as a paint material, and more particularly as a varnish compound, has been largely discouraged for the reasons that I have cited:

First.—Because it is no good.

Second.—Its price has been so low that it was used as an adulterant or a cheapening material.

HISTORY OF CHINA WOOD OIL

But the advent of china wood oil has brought about a change, and I am unafraid to admit that, while I despised and discouraged the use of it in my own factory, I am now a firm believer in it; and, until something better can be discovered, rosin has at last come into its own.

Let us remember that fifteen years ago china wood oil was condemned because its physical characteristics were compared with linseed oil, which shows us that it is a mistake to take a new material and judge it by an older one. Raw linseed oil, as everyone knows, dries with the aid of a drier, and when suitably mixed with the proper pigments forms a film which lasts anywhere from three to eight years, even under extreme exposure.

Raw china wood oil, on the other hand, no matter what it is mixed with, dries with an opaque, brittle, crystalline film, which is neither flesh nor fowl. It polymerizes or solidifies when heated for twenty minutes to 420 deg. F. (216 deg. C.). It is difficult to manipulate and in unskilled hands it is a failure. But when 4 lb. of china wood oil is heated with 1 lb. of rosin that

*Read before the American Institute of Chemical Engineers, Dec. 5, 1919, Savannah, Ga.

has been partially or wholly converted into a resin ate of lead or similar compound, the heat can be carried up to 600 deg. F. (315 deg. C.) without danger of the polymerization of the oil, and a varnish is obtained which, while fairly high in acid number, possesses more remarkable qualities than the best kauri linseed oil varnish ever made. This sounds strange, but it is true.

Of course, to those skilled in the art it is known that this resultant fusion of 5 lb. just mentioned must be diluted with equal quantities of turpentine or turpentine substitute, and the film so produced will not turn white after it has been permitted to dry thoroughly, even though the test sample is placed in water for weeks. When I made my first experiments along these lines I did not use the material as a varnish, but I used it as a paint oil. Of course, lead and zinc could not be used as bases, because chemical union would take place, and the compound, which I called a tungo resin ate of lead or zinc, was formed, which was a viscous, ropy, gelatinous material, physically unfit for making paint ready for use. But, if the proper pigments were selected, such as graphite lithopone, red oxide and blanc fixe, a paint could be made which remained in suspension for a long time.

As many know, I do not rely upon laboratory experiments for the finding of my conclusions; but in 1915 and 1916 I made several hundred gallons of various colored paints, omitting linseed oil entirely as a vehicle, and substituting for it a varnish made from rosin and china wood oil, and these paints I applied to wooden structures on the Atlantic coast which were from 100 to 500 yd. distant from low tide and subject, therefore, to the heavy sea fogs of that locality. In comparison with these tests there were a number of smaller buildings painted with various mixtures of lead and zinc and linseed oil, and the conclusions arrived at were that the gloss and hardness of the resulting film, after three years, was as good for the rosin:china wood oil mixture as for the linseed oil paint, with this exception—that the rosin:china wood oil paint left a better surface for repainting.

REVERSAL OF STATUS OF ROSIN

Rosin forms esters with certain alcohols like glycerine and phenol, in which the rosin acts as the base and the alcohol as the acid; so that, under certain circumstances, if we follow the experiments of Schall and use a silver-lined or aluminum kettle, we get a glyceride of rosin which is soluble in china wood oil at temperatures up to 600 deg. F. (315 deg. C.), and the resultant varnish has a very low acid number ranging between 7 and 15, which makes it more suitable for mixtures with lead and zinc. But, used alone, rosin esters produce waterproof varnishes which are so far superior to the linseed oil-fossil resin varnishes that the newer specifications of the Government not only permit their use, but encourage it. Specifications used by the Railway Commission and other branches of the Government service are quoted below:

RAILWAY FINISHING VARNISH

It must be resistant to air, light and water. The manufacturer is given wide latitude in the selection of raw materials and processes of manufacture, so that he may produce a varnish of the highest quality. Preference will be given to rapid drying varnishes.

FLAT FINISH INTERIOR WALL PAINT

The paint supplied must be ready for use for finish coat work. There shall be present not less than 65 or more than 70 per cent of pigment. The vehicle must

be composed of treated oils and volatiles, or varnishes which produce a satisfactory washable flat finish.

DECK AND FLOOR PAINT

The vehicle shall consist of linseed oil and sufficient waterproof varnish to give the paint a high gloss and resistance to abrasion and water. The varnish in the paint shall conform to the general specifications for varnish.

SPAR VARNISH FOR USE IN AIRPLANE CONSTRUCTION

The manufacturer is given wide latitude in the selection of raw materials and processes of manufacture so that he may produce a varnish of the highest quality. Rapidity in dust-free drying and final hardening is essential.

It may interest the public to know that nearly all automobiles are varnished nowadays with varnishes of this type. There again, I have conducted a large series of experiments, having painted and varnished no less than twenty automobiles in the last four years with this particular type of varnish. I have the record of one particular automobile which, after one year of hard service in all kinds of weather, is still brilliant and glossy and does not need revarnishing. Rain, sleet or snow has no effect on a varnish of this type and does not produce the well-known bloom or bluish spots so familiar to those seen in linseed oil varnish.

Since the war the price of rosin has risen until it is today such a high-priced material that we will not frown down upon it on account of its low price.

ONCE DESPISED MATERIALS NOW PRECIOUS

Human nature is very peculiar with reference to the embrace of materials which once were despised and come under the category of that well-known stanza in Pope's *Essay on Man*—"We first abhor; then pity; then embrace." Everyone of us can remember when the metal platinum was only used in the laboratory because of its insolubility and high melting point. Its price when I was a student was about one-third that of gold, or even less. As the price rose and it became a really expensive material, two and a half times dearer than gold, it was fashionable to use it as a setting for diamonds, even though its color was leaden and the polish soon dimmed. Now that platinum is worth five times more than gold, it is idolized by the rich only, it would seem, on account of its price.

Turpentine has always been regarded as the ideal paint solvent, and specifications, tests and laws have been made to prevent the adulteration of turpentine with the petroleum products. Yet in 1911, the price of gasoline in Italy was twice that of turpentine. Furthermore, there was no tax on turpentine, but there was one on gasoline, and it was a criminal offense in Italy to adulterate gasoline with turpentine.

A hundred and fifty years ago, when a good slave was sold in the South, particularly along the coast, the deed usually recited that the slave must not be fed on terrapin, which, as you know, is a species of turtle that was once so abundant that it was even despised by the negroes as food. But when the terrapin became rare, and finally a small portion of it—hardly more than 100 grams—sold in restaurants for \$3.50, only the elect few and the newly rich regarded it as fashionable to eat terrapin.

Five years ago rosin sold at about 2c. a lb., and today it has gone to 10c. a lb. Legitimate uses of rosin will raise its price so that who knows but some day it will be considered criminal to adulterate rosin with the fossil resins of the Orient?

Electric Furnace for Experimental Work*

By F. A. J. FITZGERALD AND GRANT C. MOYER

IN OUR work we have found that for a variety of small-scale experiments the furnace which is shown in the drawings illustrating this note and which we use in the laboratory has been found by us convenient and satisfactory.

FIG. 1. END VIEW OF FURNACE

The furnace is mounted on a truck built of channel irons, a pipe framework and boiler plate. The electrode holders and their working mechanism are mounted on the boiler plate, and the furnace is built on this. The electrode holders are aluminum bronze castings and are moved to and fro by means of right- and left-handed screws respectively. The shaft of each screw terminates in a gear engaging with gears mounted on a shaft which passes under the boiler plate base and which has a hand wheel mounted at one end. By this hand wheel one worker can attend to the running of the furnace. The hand wheel shaft is in two parts connected with a coupling and near this is a small collar on the shaft. This arrangement is used to form what we call a "gear lock," which consists of an iron bar held between the collar and the coupling. This bar is hinged and can be dropped down so that the hand wheel shaft may be pushed longitudinally in its bearings sufficiently far to throw the gears out of mesh.

*Paper read at the meeting of the American Electrochemical Society in Chicago, Sept. 23-26, 1919.

FIG. 3. PLAN OF A SECTION OF FURNACE

This allows the electrode holders to be separately adjusted when desired. The water-cooling rings are bronze castings and slide on the electrodes. They are hollow and open at the top so that they can be kept filled with water, thus cooling the electrodes. The rings should not be in the position shown in the drawing, but should be pushed up close to where the electrodes pass through the furnace walls.

FIG. 4. DETAILS OF ELECTRODE HOLDERS

As shown in the drawing, the furnace is built up so as to heat the charge in the crucible by radiation from the arc. In our work we generally use a current at 50 volts and 500 to 1000 amperes.

The apparatus can also be used for other kinds of furnaces; for example, for heating a crucible embedded in granular carbon. When used in this way convenient electrodes are 4 x 4 in. (10 x 10 cm.) graphitized carbons. Fig. 4, besides showing details of the electrode holder construction, shows modification for use with 4 x 4 in. carbons. The mobility of the electrodes permits of considerable variation in the resistance of the furnace while running with a granular carbon resistor.

The furnace also is convenient for heating the central portion of a horizontal tube embedded in a granular carbon resistor, and, of course,

FIG. 2. SIDE VIEW OF FURNACE

it may also be used as a furnace in which the tube is heated by an arc on the outside, but in this case the 1½-in. (3.8-cm.) electrodes are used.

While there is nothing original in the general principles of the furnace, it is believed that the detail design may be found as useful by others as it has by us, on account of its being so cheap and easy to construct.

FitzGerald Laboratories,
Niagara Falls, N. Y.

Experience With a 91:9 Copper-Aluminum Alloy

BY A. I. KRYNITZKY*

AFTER many experiments in the foundry of the Time Fuse Plant in Petrograd, Russia, with different copper-aluminum alloys it was decided to use an alloy containing about 9 per cent of aluminum. It might be stated in advance that with 10 per cent aluminum or more it is very difficult to obtain a homogeneous alloy, particularly with a single melting. In most cases the fracture shows a liquation and also a coarse crystalline structure.

Referring to the equilibrium diagram, these alloys—9 to 10 per cent of aluminum—are very close to the point α_1 (see Fig. 1). We have to expect here the presence of homogeneous alpha solution in the case of annealed alloys containing 9 per cent or less of aluminum; and in the case of 10 per cent or more aluminum, secondary alpha crystals within the primary beta, and also alpha and gamma crystals within original grains of beta.

*Formerly chief inspector of time fuses for the Russian Government in the United States; now assistant physicist, Bureau of Standards, Washington, D. C.

Concerning the process of casting, in the first place a well known fact was confirmed, that the temperature of the casting is of great importance. The alloy must be poured at a temperature very near its melting point, which in the absence of a pyrometer is difficult to get because of the formation of a thin film, which makes observation difficult. Chill casting is better than sand casting.

PURITY OF RAW MATERIAL IMPORTANT

The purity of the raw material is, as usual, very important. This fact was confirmed in these experiments with four kinds of copper used: Mansfeld copper, Bare, Tamarack and a Chinese brand. While uni-

FIG. 1. PART OF EQUILIBRIUM DIAGRAM FOR COPPER-ALUMINUM ALLOYS, FROM G. H. GULLIVER. FIG. 2. SKETCH SHOWING NATURE OF BREAK IN SPLIT RODS

formly good results were obtained with the first three kinds of copper, the last one gave very bad results; it contained a relatively large amount of oxygen.

There was no opportunity to compare different kinds of aluminum, as only one kind was used: aluminum of Neuhausen, Switzerland. Analysis of the above-men-

tioned first three kinds of copper showed very close to 99.6 per cent copper. Analyses of the aluminum were very close to Al 98.81 per cent, Si 0.45 per cent, Fe 0.44 per cent.

All work was done under manufacturing conditions. The alloy was melted and cast in the ingots and then remelted (sometimes more than once) in crucibles, in an oil-fired furnace, a thin layer of charcoal being used to cover the charges to prevent oxidation. For stirring the melts graphite rods were used exclusively.

As before noted, the use of an alloy with 10 per cent or more aluminum is not recommended, since such an

pulled on a Mohr and Federhaft machine. The averages of these results are given in Table I.

As to lot No. 21, which was subjected to high, medium and low forging; the difference in the degree of forging was attained by first removing different amounts of skin by means of a sharp die. The less skin removed, the greater the forging subsequently applied.

Concerning lot No. 34 it should be noted that metal cast and quenched immediately in cold water shows less ductility and tensile strength than the same cast when slowly cooled.

To the writer's regret this work, because of circumstances, was discontinued and no more data were obtained. Therefore no positive conclusion can be drawn as to the nature of the peculiarities appearing. Referring to the equilibrium diagram (Fig. 1) it might be said, however, that in both cases (rapid quenching in cold water and slow cooling) we would expect to get only the alpha solution.

CONE SHAPED FRACTURE

Some of the rolled bars 1.240 in. in diameter were experimented with for the manufacture of primers.

The bars were cut into cylinders and cold pressed in a hydraulic press, the faces being perpendicular to the axis. Sometimes the cylinders could not withstand the pressure and were consequently broken, always in a characteristic way, a cone shaped piece coming out of the top, as shown in Fig. 6.

FIG. 6. SECTION OF PIECES WHICH FAILED UNDER COMPRESSION

Attention is called to this fact in connection with the breaking of rods during cold rolling, as was previously illustrated in Fig. 2. This

phenomenon reminds one of the fracture of malleable cast iron under pressure.

MACHINING

Machining these alloys is not difficult. Small pieces, of course, will crack if not machined at medium speed, with good tools and with a cooling solution.

Washington, D. C.

Glauber's Salt in Siberian Lakes

The following is an estimate of supplies of precipitated Glauber's salt in some of the Siberian lakes: (1) The Great Marmyshansk Lake—144,000,000 poods (2,600,000 short tons) of crystalline salt ($\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$) and 22,000,000 poods (397,210 short tons) of evaporated Glauber's salt; (2) Little Marmyshansk Lake—25,000,000 poods (451,400 short tons) of crystalline salt; (3) Lake Tuskar (Minusinsk district)—up to 100,000,000 poods (1,805,500 tons) of crystalline salt; (4) Lake Varche (Minusinsk district)—up to 100,000,000 poods (1,805,500 tons) of precipitated crystalline salt and an enormous quantity of Glauber's salt in solution.

Samples Exhibition to Be Held at Trieste

Consul O'Hara cables from Trieste that an announcement has been made of a permanent samples exhibition to be held at Trieste under the auspices of the Chamber of Commerce. A special building will be erected for the purpose, which is expected to be ready by next summer. The consul considers this an excellent opportunity for American exporters to display their goods.

FIG. 3. SAND-CAST BARS

alloy requires too many precautions in its manufacture. From our experience it was found that in most cases the cast rods had many blow-holes and contained along the axis a material which showed up very definitely in cross-section as a gold band against the gray-white background of the alloy.

FRACTURE DURING ROLLING

High aluminum rods during cold rolling were easily split in two parts, the fracture very often showing almost regular teeth, as in Fig. 2. Also in case some good rods could not stand more or less severe cold roll-

FIG. 4. CHILL-CAST BARS

ing, they in most cases were broken in a similar manner.

It is important to note that this phenomenon has never occurred (at least in the writer's practice) with other alloys, such as different kinds of brasses, bronzes, aluminum alloys, etc. The explanation we have to seek in the structure of the alloy.

ROLLING AND DRAWING

The cast rods were cropped off, the skin removed by forcing through sharp dies, they were then annealed, cold rolled and drawn, annealing being applied between

FIG. 5. TEST BARS

passes. The skin was removed also before drawing, and, besides, sometimes between some draws.

Fig. 3 shows the dimensions of sand castings, corresponding to finished bars of various diameters.

Fig. 4 shows chilled castings which correspond to the finished bars of final diameters 0.570, 0.680 and 0.750 in.

TENSILE TESTS

Lots Nos. 1, 2, 3, 4 and 21 contained about 10 per cent of aluminum; the rest of the lots were cast of an alloy containing about 9 per cent of aluminum. Several test bars (see Fig. 5) were taken from every lot and were

Electrical Treatment of Sewage—Landreth Process*

SEVERAL electrolytic methods have been suggested for the purification of sewage. The first to be experimented with, the invention of Webster, was installed at Corness, England, in 1889. In this process the raw sewage flowed in contact with iron electrodes through long troughs; a current of 0.9 amp. was maintained by an e.m.f. of about 2 volts. For treating raw sewage the estimated consumption was 240 lb. of iron and 450 kw.-hr. per million gal. In this process the oxygen liberated at the anode was mostly consumed in oxidizing the iron electrodes; the oxides thus formed acted as a precipitating agent for the sludge of the sewage; the process was therefore chemical rather than electrical. The second process to be experimented with attempted disinfection by means of nascent chlorine liberated by the electrolysis of a soluble chloride. In the earlier installations a chloride was mixed with the sewage and the solution electrolyzed; later sodium hypochlorite produced electrolytically was added to the sewage. In 1893, at Brewster, N. Y., this latter method was used under the direction of the New York City Health Department. About 1600 lb. of salt was used per million gal. and the plant required 700 amp. at 5 volts.

Kennicut, Winslow and Pratt¹ summarize the electrolytic methods of treatment so far developed as being a question of the cost of supplying the disinfectants and precipitants needed; usually this cost is not in favor of electrolysis in the presence of sewage.

The failure of sedimentation thoroughly to clarify sewage led to the introduction of the chemical precipitation method, and lime was the first precipitant to be used. This method is open to the objection that the addition of too much lime renders varying amounts of the suspended organic matter soluble, which causes the effluent to be more putrescent and obnoxious than that from ordinary sedimentation.

THE LANDRETH DIRECT OXIDATION PROCESS

In the Landreth direct oxidation process for the treatment of sewage, both electricity and lime are employed. The efficiency of the process depends on the combination of these two agents; neither alone produces as good results. Oxygen and hydrogen liberated at the electrodes in the nascent state are claimed to promote the destruction of pathogenic bacteria, also to reduce nitrogenous matter to nitrites, nitrates and carbon dioxide. The presence of lime furnishes an alkaline medium and renders the electrodes passive, thereby reducing the amount of iron going into solution; the lime also assists sedimentation. This process was extensively studied at a 750,000-gal. plant at Elmhurst, L. I., in 1915, later at Decatur, Ill. During the spring of 1918 a million-gal. plant was constructed at Easton, Pa., by Mr. Landreth for demonstration purposes.

DESCRIPTION OF PROCESS

The raw sewage upon entering the plant passes through a coarse screen over a screen having six 0.25-in. holes per sq.in., is then elevated by a centrifugal pump passing over a measuring weir to the electrolytic tanks, then through an observation flume and is dis-

charged either through a sedimentation tank or direct to the river.

The electrolytic apparatus consists of a horizontal cypress box 27 ft. 3 in. long, 3 ft. wide and 2 ft. 9 in. deep. The removable top is constructed in two sections and can be made watertight by means of bolts and rubber gaskets. Each section of the top is vented for the removal of the gaseous products of electrolysis. A series of valves at the bottom of the tank serves for the removal of sludge.

Internally the tank is divided into eleven spaces, each of which contains two banks of electrodes mounted one above the other, giving a total of 22 banks of electrodes arranged in two horizontal rows of eleven each. These banks of electrodes, each of which consists of 48 plates of mild steel 10 in. by 16 in. by $\frac{1}{8}$ in. spaced $\frac{1}{2}$ in. apart, are placed across the box, the plates being vertical and parallel to the sides. The 48 plates of each bank are electrically connected so that alternate plates have the same polarity, the 22 banks being connected in series. The tank is so constructed that the entire flow of sewage is through the $\frac{1}{2}$ in. spaces between electrodes. Paddles revolve in each of the spaces between electrodes at 20 r.p.m. The total electrode area is 124,287 sq.in.

DESCRIPTION OF OPERATIONS

Milk of lime is added at the measuring weir by an apparatus which permits of close regulation, and the amount added is sufficient to give about 30 p.p.m. excess CaO in the effluent. The polarity of the electrodes is changed at regular intervals to reduce polarization. Calcium carbonate tends to crystallize on the electrodes and has the effect of increasing the power required by the stirrers; whenever the power consumption reaches 2000 watts the addition of lime is discontinued. The acid in the raw sewage dissolves these crystals, reducing the power consumption to normal, or to about 1100 watts, when lime is added again at the inlet of the tanks. During this operation lime is added at the observation weir. The voltage of the individual cells ranges from 2.5 to 3.7 volts, averaging 2.82 volts with a current of 34 amp.

EFFICIENCY AND COSTS

The efficiency of any method of sewage treatment cannot well be shown by a tabulation of results, due to the large variation of the raw sewage and to the means of disposal of the effluent; these are determined by local conditions. It is usual to design a plant to meet these conditions. The amount of dissolved oxygen absorbed by an effluent is an important standard; the effluent from the Landreth process is below the most stringent standard in this respect. The average absorption of dissolved oxygen upon standing five days was 0.77 p.p.m., whereas the very strict standard of the Royal Commission on Sewage Disposal allows 30 p.p.m. as a maximum. The effluent produced by the Landreth process is considered highly satisfactory.

A million-gal. plant would consume power at the rate of 335 kw. and 90 per cent lime at the rate of 800 lb. per million gal. A typical plant for treating sewage from a town of 55,000 population can be operated at a cost of 64c. per capita. An "activated sludge" plant would cost \$1.10 and an "Imhoff-trickling filter" plant 82c. per capita. A Landreth plant has the additional advantage that it requires only a small ground area and can be operated and installed in a thickly populated district without being offensive.

Effect of Surface Tension on Crystalline Form*

BY CECIL H. DESCH

Professor of Metallurgy in the Royal Technical College, Glasgow

THE investigation which forms the subject of these reports was undertaken at the instigation of Sir George Beilby to test the hypothesis of Quincke, according to which metals and other substances, immediately before solidification from the liquid state, separate into two immiscible liquids, one of which is formed in much smaller quantity than the other. These liquids have an interfacial surface tension, and a foam is formed, the liquid present in smaller proportion arranging itself in cell walls, and the second constituting the cell contents. Crystallization then takes place within the foam cells, and the cell walls are represented in the solid mass by the boundaries of the crystal grains.

If this were actually the case, the form of the crystal grains in a solid metal might be expected to approximate to that of the cells in a foam, such as is produced by blowing air through a soap solution, the shape of the cell walls in both cases being due to surface tension. The subsequent growth of the crystals forming the cell contents might distort the original cells, but could scarcely produce a complete change of type.

THEORETICAL FORM OF FOAM CELLS

The problem of the form of individual cells in a foam has received surprisingly little attention. The fundamental principles were established by Plateau in his classical investigations,¹ and may be stated as follows:

(a) Only three films can meet in an edge, and they must make equal angles of 120 deg. with each other;

(b) Only six films can meet at a point, and adjacent edges must make equal angles of 109 deg. 28 min. with one another.

The foam being the result of surface tension, the area of each cell is necessarily a minimum for the given conditions. The arrangement of the dividing walls in a single layer of bubbles on the plane surface of a liquid is easily shown to be a regular hexagonal pattern.

The beautiful experiments of Plateau did not include the examination of a mass of foam. A solution of this problem was obtained by Lord Kelvin.² The most general solution for the homogeneous division of space was shown by him to be a tetrakaidecahedral cell, consisting of fourteen walls, which may be plane or not plane (Figs. 1 and 2). Eight of these are hexagonal and four quadrilateral, so that there are thirty-six edges and twenty-four corners. Each face is common to two neighboring cells; each edge is common to three cells, and each corner is common to four cells. Any homogeneous assemblage of similarly shaped and similarly oriented objects, however irregularly shaped, may be divided from one another by similar cells of the above type, in such a way that every single object is completely inclosed in one cell. The simplest example of such a cell may be obtained by truncating the six

corners of a regular octahedron to such a depth that the eight original triangular faces are reduced to equilateral equi-angular hexagons.

Foam cells are subject to the further condition that the partitional area must be a minimum. The tetrakaidecahedron of minimum area has been shown³ to have also eight hexagonal and six quadrilateral faces, all the edges being equal in length; but the latter, instead of being straight lines, are now similar plane arcs. The condition being that the edges must meet at an angle of 109 deg. 28 min., each arc is one of 19 deg. 28 min. It is not actually circular, but may be considered as such without serious error. The figure may be constructed very simply by stiff brass wires soldered together to form the required figure. Such a wire model, immersed in soap solution, gives a giant foam cell, the faces of which have the required form. The hexagonal films are doubly curved in such a way that the three diagonals are straight lines lying in one plane, and the sum of the curvatures in mutually perpendicular normal sections at any point is constant. A mass of foam built up of similar cells of the above shape would be stable.

The rhombic dodecahedron, Fig. 8, is a plane-sided polyhedron, of which each pair of sides meets at an angle of 120 deg., and space may be filled with equal

FIGS. 1 TO 3

Fig. 1—Tetrakaidecahedron with plane faces. Fig. 2—Tetrakaidecahedron of minimum area. Fig. 3—Regular pentagonal dodecahedron.

and similar rhombic dodecahedra. Moreover, it is the only plane-sided polyhedron which fulfills these conditions, but foam cells of this form are unstable, since it involves the meeting of twelve plane films at a point, an unstable equilibrium which may be departed from in three different ways.

EXPERIMENTAL EXAMINATION OF FOAM CELLS

In order to prepare a foam, some solution is poured into a glass trough with plane parallel sides, and air is blown through it by means of a narrow pipette until the trough is filled with foam. When a fairly stable condition has been reached, single cells are examined by placing the trough in front of a window, screening it with a sheet of black paper having a hole about 2 cm. in diameter, so that the attention is more easily concentrated on a single cell. An attempt is then made to count the cell walls, and to record the number of edges of each face. This is done for as many cells as possible. The direction of curvature of the walls may often be recognized by the arrangement of the bands of color under illumination. A second method consists in making a foam from a warm solution of gelatin, of sufficient concentration to set on cooling. The foam cells are thus fixed, and may be examined at leisure, each cell being cut open and examined in turn by using fine-pointed dissecting scissors. Both methods have been employed in obtaining the results shown below.

*Second report (slightly condensed) to the Beilby Prize committee of the Institute of Metals on the solidification of metals from the liquid state, presented Sept. 24, 1919. The first was presented to the Institute at the spring meeting of 1914, and consisted of a review of the state of knowledge respecting the solidification of metals from the liquid state.

¹J. Plateau, *Statique expérimentale et théorique des liquides*, 2 vols. Ghent, 1873.

²*Proceedings of the Royal Society*, 1894, vol. 55, p. 1; *Collected Papers*, vol. 5, p. 333.

³*Philosophical Magazine*, 1857, vol. 21, p. 503; *Collected Papers*, vol. 5, p. 297.

The forms of the cells were found to be essentially the same in all cases.

Even a casual examination of a mass of foam shows that the individual cells vary in form, but however irregular they may appear, it is easily seen that the faces and edges fulfill the conditions established by Plateau. Occasionally, when movements are in progress in the midst of the mass, four films may be seen to meet in one edge, but the position is unstable, and slid-

(The first two preparations, in which the largest number of cells was counted, were the most regular in structure. Some cells proved to be complete pentagonal dodecahedra. The gelatin preparations, no doubt owing to viscosity, were the most variable.)

ing immediately takes place until equilibrium is reached. The vertices of large cells are often truncated, and a small cell is then interposed between the larger neighbors. Such transitional cells are either hexahedra, elongated in one direction, and having the edges slightly curved so as to make angles of 109 deg. 28 min. with one another instead of 90 deg., or tetrahedra, the edges of which must be strongly curved.

The results of observations of several masses of foam, prepared at different times and by different methods, are given in Table I. It is at first sight surprising that an approximation of Lord Kelvin's tetrakaidecahedron should be so rare. If this were the usual type of cell, four- and six-sided cell walls would occur with frequencies in the ratio of 6 to 8, but the observations show that five-sided faces are much more common than either, and that hexagonal faces are comparatively infrequent. The cells often approach very closely to the form of a regular pentagonal dodecahedron (Fig. 3). This figure has faces with five equal angles of 108 deg., thus coming very near to the required angle of 109 deg. 28 min., and adjacent faces meet at an angle not far from the equilibrium value of 120 deg. A slight curvature of the edges therefore converts the pentagonal dodecahedron into a possible figure of equilibrium for a foam cell.

EXPERIMENTAL EXAMINATION OF CRYSTAL GRAINS

The next step is to examine the forms of crystal grains in cast metals, and to determine how far they correspond with those of foam cells. For this purpose advantage was taken of a fact mentioned by Professor Huntington in the discussion on the previous report,⁴ that β -brasses containing aluminum, when immersed in mercury, separate into distinct grains, the mercury penetrating between the grain boundaries. A suitable mass of metal was available, and the coarse grains thus isolated had a brilliant, silvery surface, owing to amalgamation. They could be examined under a hand lens, each face being marked with a dot of ink after noting the number of its sides and the direction of its curvature. The results of the examination of thirty of these grains are shown in Table II. The number of

faces is usually large, varying from 11 to 20, with an average of 14.5. Generally speaking, the larger grains are the more complex. The faces are mostly curved, and double curvature, recalling that of foam cell walls, is frequent. It will be seen that there is a great preponderance of pentagonal faces. The figures are plotted in Fig. 4 for comparison with those given by the counting of cells in soap and gelatin foams, and the general resemblance of the two curves will be noticed.

Attempts have also been made to separate other metals in the same way, but the number available was small, and it was not thought worth while to present the figures separately.

EFFECT OF SUPERFICES

The preceding remarks concerning the forms of foam cells and crystal grains are applicable only to cells which occur in the midst of a large mass, and are therefore independent of boundary condition. Where

FIGS. 4 AND 5

Left—Shape of brass grains compared to foam cells. Right—Shape of boundary grains of ingot compared to foam cells.

the wall of a foam cell meets a solid surface, such as the glass of the containing vessel, it does so at an angle of 90 deg. The partitioning of neighboring cells is still subject to the condition that only three walls can meet at an edge, and that the angle between them must be 120 deg. The most natural arrangement then becomes a regular hexagonal pattern. Actually, as the

TABLE II—GRAINS IN PROPELLER BRASS IN β -CONDITION

		3	4	5	6	7	8
β -brass . . .	14.5	11	88	190	123	20	3

cells vary in size, polygons having a variable number of sides are observed, but the hexagonal form predominates. Figures for soap and gelatin films are given in Table III, and are represented graphically in Fig. 5.

A convenient metallic object for comparison was a small ingot of crucible steel, the fracture of which showed dendritic crystals extending from the four surfaces to the center of the ingot. One of the outer faces was polished and etched, so giving a transverse section of the dendritic crystals close to their origin.

The polygonal outlines thus exposed were examined as above and the results are shown in Table IV and Fig. 5. Some of the grains were very complex, and it is probable that a certain amount of coalescence takes place between neighboring dendrites, giving rise to compound grains, the outlines of which are more or less irregular.

While it has only been found practicable to examine isolated crystal grains in exceptional cases, it is always possible to make plane sections through the metal, and to examine the shape of the grain boundaries exposed in that section by etching. Such boundaries often have a simple polygonal form, and it would appear at first sight that it should be possible, by counting the sides of a sufficiently large number of polygons, to infer from the result the probable form of the polyhedra of which they are the sections, provided that those polyhedra are either similar or vary closely about a mean type. Unfortunately, the problem of establishing a relation between the form of a polyhedron and that of its plane sections proves to be peculiarly difficult. The mathematical problem on which the solution depends may be stated simply. It is: given the form of a polyhedron, what is the probability that a plane section, drawn through it at random, will have 3, 4, 5, . . . n sides? A general solution, even for a simple case, such as a cube, does not appear possible. One is therefore reduced to some geometrical expedient.

A rough experimental method has been adopted, models of the polyhedra being made in cardboard, and rendered waterproof. By immersing these, plane sections are realized by the intersections of the model, placed in various positions, with the surface of the water. Placing the model with a selected line vertical, it is immersed by successive equal steps, such as 1 cm., and the form of the intersection is noted at each step. Experiments of this kind have been made with models of the rhombic dodecahedron, pentagonal dodecahedron, and orthic tetrakaidecahedron.

As an illustration of the method adopted, the first of these solids may be taken. The model may be im-

FIGS. 6 AND 7

Left—Number of sides on figure cut from crystals by random planes. Right—Shape of crystal intersections in metallographic prints.

mersed with one face horizontal. The height of the model employed being 13 cm., 14 sections at distances of 1 cm. are obtained, of which 8 are four-sided and 6 are six-sided. As there are 12 rhombic faces, to any one of which the section might be parallel, these numbers must be multiplied by 12. Similarly, any one of the 24 edges might be placed horizontally, like the ridge of a

roof, or a vertex might be placed uppermost, there being 8 trihedral and 6 tetrahedral vertices. A vertex being tilted to one side, a fresh set of observations is made, and so on. The curve drawn in Fig. 6 represents the relative frequency with which each section occurs, a total of 1732 sections having been used for its construction. The curves for the other polyhedra have been constructed in the same way.

There is no certainty that sections thus arbitrarily chosen will be distributed in the same way as those found at random, but the number taken is large, and it seems worth while to test it. Small errors may also be introduced by accidental irregularities in the models. The metal specimens used for comparison with the above figures included the same brasses which had furnished the isolated grains, two pieces of very mild steel, having polygonal grains with remarkably straight boundaries, and several miscellaneous specimens which were used for purposes of comparison. The results are shown in Table V, and are represented graphically in Fig. 7.

An examination of the tables and curves makes it evi-

to the average crystal grain, as the distribution is not sufficiently characteristic.

ASSUMPTION OF EQUIDISTANT NUCLEI

If we suppose that surface tension has nothing to do with the form of the crystal grains, but that these are determined solely by growth from centers, a conclusion may be reached as to the form to which such grains should approximate. It seems likely that in a sufficiently large mass the nuclei should be approximately equidistant. This would be equivalent to the close packing of a large number of spheres. It is known that such close packing may take place in one of two ways, known respectively as the cubic and the hexagonal. If we imagine closely packed spheres to be made of some deformable substance, such as plasticine, and pressure to be then

applied so as to close up the interstices, a mass of polyhedra will result. Cubic packing leads to the formation of regular rhombic dodecahedra, and hexagonal packing to that of dodecahedra which have certain of their faces no longer rhombs, although still quadrangular. (See Figs. 8 and 9.⁶) Whichever were formed, the grains would have quadrangular faces, and in a mass of metal solidifying under such conditions the grains might be expected to show a preponderance of 4-sided faces. This is not confirmed by the observation of grains isolated by the mercury method. If, however, the form of the grains were determined by surface tension, they might be expected to approach more closely to the pentagonal

FIGS. 8 AND 9

Fig. 8—Rhombic dodecahedron from cubic packing. Fig. 9—Dodecahedron from hexagonal packing.

dodecahedron, or to the tetrakaidecahedron, or to some compromise between the two. This is confirmed by the results shown in Fig. 4, there being a marked preponderance of faces with 5 edges, followed by 6 and 4.

RELATION BETWEEN DIRECTIONAL IMPULSE AND SURFACE TENSION

There is thus evidence that the forms of the crystal grains in at least some metals are such as might be expected if surface tension were concerned in their determination. On the other hand, it is well known that many crystal grains are less simple, and exhibit complex interlocking. There is a striking difference between α - and β -brasses in this respect. α -brasses usually have interlocking boundaries, and rarely approach simple polyhedral forms. Iron and steel may form either polyhedra or interlocking grains, according to circumstances. One is forced to the conclusion, previously expressed by the writer,⁸ that two forces are competing in the formation of crystals. One is the directive force of cohesion, sometimes called the crystallizing force, and the other is surface tension. The ratio which the one bears to the other varies with the nature of the crystalline substance, the temperature of crystallization, the composition of the mother liquor, and the absolute dimensions of the mass of the solid. When the mass is very small, so that the surface is large relatively to the volume, the surface forces may be so great as to mask the crystallizing tendencies completely. This aspect of the subject has been specially studied by Sir George Beilby.⁷ With larger masses the other factors become more important, and the specific differences between different metals become particularly noticeable. It will be seen, however, that a metal which has a great power of orientation will be likely to form interlocking grains, as the boundaries will be chiefly determined by the growth of the crystallites, while a second metal, in which the orienting forces are weaker relatively to the surface forces, will tend to form grains of a simpler character, surface tension intervening to check the growth.⁹

Reference may here be made to one case in which

an isolation of crystal grains has been effected, but in which only complex forms have been observed. This is the case of glacier ice, the crystals of which have not been formed directly from the liquid state, but re-formed from the original minute snow crystals by successive partial fusion and regelation under the influence of non-uniform pressure. The action of sunlight sometimes causes a mass of glacier ice to disintegrate into grains, which are readily separated from one another. These grains do not appear to be of simple form, but interlock in a complex fashion. "The shape of the grains is irregular, and no two of them are alike, but they fit into each other like a puzzle. They resemble a collection of vertebræ more than anything else."¹⁰ It is not proved that such disarticulated masses, which vary in size in a single mass of glacier ice from $\frac{1}{2}$ to 700 g., are actually single crystal grains, and it may well be that they are aggregates of smaller units, but they are differentiated from the general mass by the ready fusion of the thin sheath of eutectic surrounding them, so that sunlight etches the outline of the grains on the inner surface of a grotto, revealing interlocking boundaries curiously resembling the sutures of the cranial bones.¹¹ It is quite possible that two orders of cellular structure are here present, this being a feature common to many solidified masses, both metallic and non-metallic.

Chicago Women Chemists' Meeting

The women chemists of Chicago recently held an informal meeting during which the discussion was devoted to the coming meeting of the Chicago Women's Section and other pertinent topics.

The second informal dinner for women interested in chemistry is scheduled for the evening of Jan. 12 at 6:30, at the Chicago College Club, 151 N. Michigan avenue. These meetings are the result of the attendants being drawn together by common interest. Among subjects for future discussion are planned the starting of business in the tanneries, pleasing the fastidious with specially dyed costumes, and similar experiences.

The Chicago Chemist Club

The Chicago Chemist Club has elected the following officers and trustees to permanent positions during the coming year: President, William Hoskins; first vice-president, Frank M. DeBeers; second vice-president, W. Lee Lewis; treasurer, Charles E. Kavin; secretary, Paul Van Cleef; trustees: one-year term, Otto Eisenschmil; two-year term, F. W. Willard, L. V. Redman; three-year term, H. O. Baker. Final arrangements have not yet been made with respect to the future headquarters of the club. Among other proposals is the use of the City Club as headquarters for the time being.

International Research Council Monographs

Professor W. A. Noyes of the University of Illinois has been recommended by the Advisory Council of the American Chemical Society as chairman of the Board of Editors of the Scientific Series of Monographs and Dr. John Johnston has been recommended as chairman of the board of editors of the technological series of monographs which are to be prepared under the auspices of the International Research Council.

Research Organic Chemicals*

Brief Sketch of the Development of Domestic Supplies of Organic Intermediates for Laboratory Research
—Illinois Vacation Quantity Synthesis Course—Department of Synthetic
Chemistry, Eastman Kodak Company

By H. T. CLARKE

UNTIL 1914 the great bulk of organic chemicals employed by research workers in university and technical laboratories was obtained exclusively from Germany, the majority being supplied by the firm of C. A. F. Kahlbaum. This firm engaged in the preparation of a certain number of the products which it listed, but the majority were undoubtedly procured from outside sources. These fell into three main classes. The first class consisted of firms making a specialty of the preparation of rare chemicals, of which the most important was that of Theodor Schuchardt of Corlitz. The second class consisted of manufacturers of specialties in which there was scant room for competition and in which one firm apparently supplied the world's demand. Examples are the essential oil laboratories of Schimmel & Co., which supplied a relatively large field, and small firms such as that of Flemming, which prepared the chlorhydrins of glycerol. The third class consisted of the large chemical manufacturers, such as the important dye and pharmaceutical plants.

Owing to the wide range of products thus obtainable from the second and third classes it was possible to supply chemical research workers a large number of necessary products at relatively low cost. The special materials prepared by Schuchardt and Kahlbaum were naturally very much more expensive, since they were prepared on a laboratory scale rather than in large scale apparatus. For example, p-nitrochlorbenzene could be purchased in pure condition for 15 marks a kilo, and in technical quality for 6.50 marks a kilo, the latter material being obtained from the dye works. On the other hand the corresponding bromo compound, which is just as readily prepared in the laboratory, was priced at 0.40 mark per kilo. Again technical p-toluidine, sold at 4.40 marks a kilo, was prepared from technical p-nitrotoluene, sold at 3.50 marks a kilo, whereas p-chloraniline, obtained from technical p-nitrochlorbenzene, was sold for 10 marks per hundred grams. The procedure of preparation is identical, but in the latter case it was not carried out on a technical scale.

At the opening of hostilities in 1914 the supply of Kahlbaum research chemicals in this country was abruptly cut off. Research work continued for some time with the use of materials in the stock houses and in the store rooms of the universities, but by the middle of 1916 the position was rapidly becoming serious and it looked as if research work was coming to a halt for lack of supplies.

RESEARCH STUDENTS PREPARE LARGE QUANTITIES OF ORGANIC CHEMICALS

During this period one attempt was made by a university laboratory to meet the shortage in its stock rooms. Dr. C. G. Derick, of the University of Illinois,

initiated a system of vacation laboratory work for the senior students in the organic chemical department, in which the materials most urgently required for the work of the coming semester were prepared in quantities sufficient to meet the immediate requirements. It may here be pointed out that this admirable scheme was of direct benefit not only to the chemical laboratory of the University of Illinois but to the students taking part in the manufacture, since in no other way would they be able to obtain the experience which was rendered possible by this system. On the retirement of Dr. Derick the work was continued under the direction of Dr. Roger Adams, who took it over at the time when the shortage of research organic chemicals was becoming acute. Dr. Adams therefore decided to throw open the facilities of his laboratory to chemists throughout the country, and by so doing was able to bring relief to the quarters where the distress was greatest. On the entry of the United States into the war this work at the University of Illinois was extended, and the laboratory was able to afford material assistance to the Government by synthesizing small quantities of chemicals unobtainable elsewhere.

EASTMAN SYNTHETIC ORGANIC CHEMICAL LABORATORIES

In July, 1918, a letter was published in *Science* from Prof. R. A. Gertner, appealing for an endowment of a laboratory in which this work could be carried out on a more extensive scale. It appeared to the Eastman Kodak Co. that its laboratory was in a favorable position to undertake the preparation of synthetic organic chemicals; and approval of the American Chemical Society was obtained, while ample assurance of support was readily given by the large chemical manufacturing firms in the country. Owing to the scarcity of chemists at that time it was decided to staff the laboratory entirely with women, both as chemists and as assistants, and this plan has been adhered to throughout the progress of the work.

The activities of the department of synthetic chemistry, as it is called, fell into three main classes: Firstly, the synthesis of materials for which there is no other source of supply; secondly, the purification of intermediate and other chemical products which could be obtained from manufacturing firms, and thirdly, the distribution of these chemicals. It was decided not only to sell pure chemicals but also to make available to research workers the various dye intermediates and technical products which could be obtained from the manufacturers. The firms manufacturing such chemicals do not welcome orders for small amounts of their products such as would meet the requirements of laboratory workers, but have willingly supplied not only 50 to 100-lb. lots of the products which they place on the market, but also many of those which they prepared

*Read before the Fifth National Exposition of Chemical Industries, Chicago, September, 1913.

exclusively for their own use. The retailing of small amounts of such materials to the chemical public is thus of benefit both to the consumer and the producer.

In addition to these technical chemicals and the pure chemicals prepared from them, there are available a number of products which, while not of the highest grade, are yet sufficiently pure for general synthetic purposes. These chemicals can naturally be held at a lower price than those of the highest purity, since in many cases more than half of the cost of the pure products is represented by purification.

Synthetic organic chemicals of value in general research have been obtained from the pharmaceutical and perfume manufacturers such as Parke, Davis & Co., Frederick Stearns & Co., the Abbott Laboratories, the Florasynth Laboratories, Antoine Chiris & Co., Van Dyk & Co. Particular mention should be made of the Dow Chemical Co., which has in several instances made special runs of particular organic chemicals otherwise unobtainable in quantity.

Continued assistance comes from the University of Illinois and from certain individuals in other university laboratories. It should here be mentioned that the excellent methods published by the University of Illinois have in many cases been adopted by commercial firms.

SIX HUNDRED COMPOUNDS LISTED

At the present time, only a few months after the beginning of the undertaking, the list includes nearly 600 different compounds, the majority of which are pure. Two considerations have influenced the selection of the substances prepared: on the one hand, attempts have been made, whenever feasible, to supply compounds for which especial inquiries had been made; on the other, the choice of new preparations has been largely determined by the materials at hand. Extensive use has been made of the ready availability of certain products which were hitherto considered as little more than chemical curiosities.

FIRMS PRODUCING SPECIALTIES •

During the past year several concerns have started the manufacture of some of the less common organic chemicals, the demand for which is not as great as is the case with dye intermediates. Mention may be made of the Digestive Ferments Co. and the Special Chemicals Co., which are manufacturing a line of pure bacterial sugars and allied compounds. The last named firm, which was organized primarily for the purpose of assisting to make the United States independent in research chemicals, is also supplying a number of general organic reagents, as are the Eimer & Amend Co., the Cyclic Chemical Co., the Research Laboratories of Chicago, the Organic Products Co., the Saginaw Laboratories and others.

CO-OPERATION REQUIRED

In order that production of research organic chemicals should be a success, it is essential that they have the support of the universities, especially during the first few years. It cannot be denied that with the present state of labor the cost of research chemicals will be considerably higher than the prices at which Germany was able to sell them before the war, and should Germany find a market for its products in this country during the initial period, there can be no doubt that the attempts to render the United States independent of

Europe in these commodities will have to be discontinued.

Their continuance is, moreover, contingent upon the success of the American chemical industries, since it is from these industries that the basic materials for the preparation of the research products must be obtained. But the success of the chemical industries depends in the long run upon the continuation of chemical research, for the country where chemical research of a theoretical nature is most intensely pursued will be the country to lead in chemical technology. The by-products of the researches carried out by university workers have formed and will form the basis of new technical processes and products.

It is therefore necessary that the materials for the carrying out of research work be close at hand; a research worker who wishes to experiment on a new line and requires special materials for his work is apt to lose enthusiasm if forced to wait three months or more for the arrival of the necessary starting products.

To further the success of chemical research and thereby to give the country the full advantages of their work, it is most advisable that university workers should co-operate as closely as possible. In order to avoid duplication of effort it would be well to permit a free exchange of new observations and products. The former is effected through the channels of the scientific publications, but very little has been done with regard to the organization of the exchange of materials. The Eastman Kodak Co. is accordingly inviting research workers to mail to it small quantities of new and interesting chemicals which they may prepare in the course of their work. Such chemicals can then be listed and distributed for research purposes. Great assistance would be afforded by universities if they were to follow the example of the University of Illinois in the undertaking above referred to, for this work has resulted not only in the output of urgently required chemicals, but—even more important—in the production of highly equipped chemists, upon whom as a class the future success of chemistry in the United States depends.

Japanese Decision on Trade Marks

The Supreme Court of Japan, in a suit instituted by a Philadelphia company for the protection of its trade mark rights, has handed down a decision which is of great importance to international trade.

The Miller Lock Co. adopted as its trade mark a scroll containing the name "Miller." This was registered in the U. S. Patent Office, Oct. 8, 1906, and in 36 other countries, date of registration in Japan being March 26, 1907. In 1916, it was found that the Crown Lock Co. of Tokyo was manufacturing imitations of the Miller padlock and stamping them with a fac-simile scroll containing the word "Crown" or "Million." Legal proceedings were instituted claiming infringement by means of the scroll containing the word "Crown." The Japanese Patent Office sustained the American owners of the trade mark. The case was then carried to the Supreme Court of Japan, which rendered a similar decision. The Court considered the question to be whether or not the imitation mark, notwithstanding the substitution of different English letters as embodied in the word "Crown" for the English letters constituting the word "Miller," would be sufficiently close to the registered mark to cause confusion in the minds of Japanese purchasers.

A Square Deal for the Electric Furnace*

By H. G. WEIDENTHAL

THE advantages of the electric furnace have been dwelt upon individually and as a whole by the proponents of the various types and makes of furnaces, and to some extent the shortcomings of the electric furnace have been brought out and discussed. Among the users of electric furnaces the great majority are enthusiastic boosters, but it is true that a small minority have found that they made a mistake in choosing a type of equipment not suited to their particular class of work. In some instances the furnace was not sufficiently rugged to stand the strain, so that the cost of upkeep plus the lost time of delays has discouraged the user.

Lack of practical melting and general steel plant experience has caused trouble for more than one high-class designer making his first attempt on an electric furnace. Designers of steel plant equipment have learned by experience that simplicity and extreme strength are essential, because of the temperature conditions to be met and because of the mental attitude of men working around hot metal. When working in the heat and under the potential hazard prevailing around a furnace or mill, men are naturally less considerate of the welfare of machinery than men working under cooler and less hazardous conditions. Failure to recognize this on the part of some furnace builders has given grounds for criticism by old steel plant men. This is unfair to the electric furnace, for it can be designed sufficiently simple and rugged to meet steel plant requirements.

SOURCES OF APPARENT DISSATISFACTION

Another source for apparent dissatisfaction among users of electric furnaces is directly chargeable to the users themselves. There are two classes of offenders. First, those who are familiar with the steel or casting business but do not appreciate the exclusiveness of the new equipment which they install. Instead of employing the proper men to operate the furnace intelligently, they buy it as they would a new cupola or a ladle and turn it over to some old "died in the wool" melter or blower to abuse as he sees fit. If this man is not exceptionally progressive, he has a fear of electricity and may even entertain hallucinations as to the effect of electric current on steel. At any rate he is seldom enthusiastic about his new care and does not give it a fair deal.

The second class of offender is the man or group of men who know little or nothing about the operating end of the steel business or casting business, whichever it may be that they embark upon. They have heard that the electric furnace runs itself and is the panacea for all the ills of the steel business. They expect by the use of this great device to sidestep the long years of apprenticeship and honest endeavor that the steel man has gone through to produce good steel. To them, pouring practice, ingot practice, cogging, forging and rolling, with their many very important details of temperatures, time of heating, etc., are merely unimportant details, for, as they think, "the electric furnace makes steel that cannot go wrong." They may even conclude that the so-called technique of steel manufacture is all unnecessary, but what happens when they try to market

their product? The steel is piped, full of blow-holes, seams, slag, and they reverse their ideas and blame it all on the furnace. Is this fair to the electric furnace?

Now at last we come to the user who is getting satisfactory results and is really pleased with his electric furnace. He is a booster for the make of furnace which he has purchased and generally speaking he is well disposed toward all electric furnaces. Apparently he is doing all he can for himself and the industry, but is he really boosting the electric furnace to the unconvinced or partially convinced user of steel?

ELECTRIC VS. OPEN-HEARTH STEEL

It is a proved fact that properly made electric steel is far superior to open-hearth steel, and that the best makes equal and in certain cases excel crucible steel. Electric tool steels have made their mark and are here to stay. High-speed steels, alloy tool and plain carbon tool steels are being made which compare well with the best crucible grades. Electric alloy die blocks are giving exceptional service and promise to put the cheaper grades off the market. Some automobile manufacturers and makers of automobile parts are specifying electric steel for drive shafts, gears, and in a few cases for drop forgings. This last field is still in its infancy, but there the need for high-grade steel is very urgent. A large number of failures in drop forgings are due to dirty steel and segregations found in the open-hearth forging steels.

Forge shops making machinery forgings, shear blades, blanking dies, etc., are beginning to appreciate the merits of electric alloy steels and are using them quite extensively.

In the steel casting business only very few plants are specializing in high-grade and alloy steel castings, although a very profitable field is being developed for alloy steel castings. The majority are competing with converter and open-hearth castings, both in price and with regard to quality. It is quite true that by using the electric furnace as a melting unit and attempting little or no refining, it is possible to produce steel for castings at the same cost or in some cases even cheaper than by the converter or small open-hearth. Another reason for the use of an electric furnace for castings is the flexibility and ease of analysis control.

TRADE NAME SHOULD STAND FOR QUALITY

It is perfectly legitimate for the casting manufacturer to take advantage of economies offered by the electric furnace, but if he does not make full use of the ability of the furnace to produce high quality steel, such castings should not be advertised as electric furnace product. The desire on the part of the manufacturer for large production and low cost should not become a reflection upon the electric furnace. It may be true that the trade does not demand a high-grade steel casting, but if "Electric Steel Castings" are sold to the trade, it should be supplied with material having a quality which is implied by the trade name "Electric Steel Castings."

Are the manufacturers of electric steel ingots, billets and bars producing the very best product that the furnace is capable of? Yes, some are producing excellent material, some are producing good material in the furnace, but are not careful enough about their pouring, mold practice, cooling, reheating, forging or rolling. Others make good steel most of the time, but feel that

*Paper read at the meeting of the American Electrochemical Society in Chicago, Sept. 23-26, 1919.

they cannot afford to remelt off heats, so they try to dispose of them either as their regular product or in some cases as open-hearth steel. Some of these heats are off in analysis, as was the case with one lately brought to the writer's attention which analyzed 0.065 phosphorus, but was sold as high-carbon chrome-vanadium shear blade stock requiring tool steel quality. Of course the steel failed and went back to the producer after the purchaser had lost a great deal of time and money trying to use it. Another very recent example is of some 3.5 per cent nickel steel for Navy work. The analysis was correct, but the steel was so full of non-metallic inclusions that it fell down miserably on its physical requirements. The writer is forced to admit that this steel was as bad or worse than any open-hearth steel he ever saw. It may be possible that in both of these instances the steel was made under adverse conditions such as bad bottom, bad roof or walls, forcing the operator to hurry the heat lest a breakdown catch him with his heat unfinished. This, however, is a poor excuse, for the proper course is that adopted by at least one plant which has a strict rule that no heat shall be rushed to completion because of furnace troubles, but that in such emergency the melter shall, as soon as possible, pour the heat without alloys. This material can only be used for remelting, and there is not even a temptation to apply it on an order. At the same time the cost of alloys is saved.

MAJOR CAUSES FOR POOR HEATS

In addition to furnace breakdowns, there are two other major causes for poor heats. One is the quick heat single slag method, that is, no dephosphorizing slag is removed. The result is not only higher phosphorus content, but all foreign substances adhering to the scrap remain in the furnace to contaminate the finishing slag. At times this practice makes it impossible to obtain the proper conditions for finishing the heat, so that the steel is no better and may be worse than the better makes of open-hearth steels.

The second cause has several angles and is not so very easily controlled. It is ignorance of proper temperatures, not only for pouring but for certain reactions which, as is not generally recognized, cannot occur except within certain temperature ranges. The common failing of pouring at too high a temperature is little worse than working a heat at too low a temperature. This temperature phase is too large a one to be included here, but would be an excellent topic for a symposium.

An investigation of the two cases above and a number of other cases where electric steels have not lived up to their reputation reveals that the makers of these steels are low bidders in each case, and the price was about that of open-hearth alloy steel. What does this indicate? It looks as if electric steel manufacturers were willing to sacrifice quality to compete in price with open-hearth steel. This is not all; some companies have gone still further; they offer "electric steel made to open-hearth specifications" at the price of open-hearth steel and another grade known as electric steel made to electric specifications at an advance of 2c. per pound over the other price. Why should there be any call for such a policy?

PUBLIC EDUCATED TO NEED FOR HIGHER GRADE STEELS

The steel-consuming public has been educated to the need of higher grade steels during the war. The elec-

tric steel maker should continue to cultivate this good seed, instead of choking it off by prejudices born of this price-cutting policy. He should remember that when the price of open-hearth steel advanced from 250 per cent to 400 per cent, the price of his own product in a very few cases advanced as much as 100 per cent in spite of the higher cost of power, labor and raw materials. Only a part of his raw materials have dropped in price, while labor and power are still advancing. Even during the artificial process of price-setting lately foisted upon the steel industry, no definite price has been set on electric quality steel, and why should the manufacturers themselves start a campaign of cutting prices, and worst of all, cutting quality?

If the electric steel producer is an intelligent business man, he must realize that one ton of carelessly made steel may curtail more sales of electric steel than he could obtain by cutting his price to below his cost. The public soon forgets the many good shipments he has made, but one bad lot of steel leaves a bad taste, which salesmanship of the higher caliber may slightly sweeten but can never completely eradicate.

An awful epidemic of poor steel has existed since the signing of the armistice, probably due to a letting down after-war tension. This applies to all grades and makes of steel, but, as before mentioned, electric steel of late has not been all that it might be. Unfortunately, a large number of steel users are not equipped to thoroughly investigate a shipment of steel before putting it into work. They often spend more than the cost of the steel in forging, treating or machining before the fact is discovered that the material is defective. Of course the maker replaces the steel, but he does not repay the user for the work he has done upon it nor for the delays due to replacement. A discriminating buyer could well afford to pay more for his steel if the maker was so sure of his product that he could guarantee not only replacement but guarantee the purchaser against any loss due to defective steel. Why not get the proper price and in turn give only the best that can be produced by the electric furnace?

Every man making electric steel, if he is a normal man, cannot help but develop a feeling of attachment for his furnace and for the industry. Let him do justice to himself and his business and at the same time give the electric furnace a square deal.

The James H. Herron Co.,
Cleveland, Ohio.

Swansea Iron Works to Adopt American Process

An American process for the sintering of fine ores and sulphide ores is about to be adopted by six iron and steel and zinc manufacturers in Swansea, Wales. A representative of a well-known American metallurgical company was recently in this district at the invitation of leading manufacturers, and placed orders with six concerns for his firm's patent machine for sintering ores. All metallurgical works using fine ores, such as iron, lead, zinc, and sulphide ores, can use this system of sintering, and it is to be expected that the future will find other local works introducing the same process. As Swansea is known as the metallurgical center of the United Kingdom and has sometimes even been called the world's center of metallurgy, great importance may be attached to this introduction of an American process for sintering. A German sintering apparatus recently adopted by a large iron and steel plant in Swansea has not been wholly satisfactory.

Tentative Regulations for the Storage and Use of Fuel Oil

Specifications of Equipment Construction: Underground, Exterior and Interior Tanks, Piping, Heating, Combustion and Feeding—150-Deg. Flash Point Regulation—Limit of Heating 40 Deg. Below Flash—Embankment Dikes—Objections and Discussion

THE Committee on Inflammable Liquids of the National Fire Protection Association at a meeting in New York, Oct. 30-31, drew up the following regulations:

Oil-burning equipments are those using only liquids having a flash point above 150 deg. F., closed cup tester. Oil-burning equipments shall be operated only when a competent attendant is constantly on the premises.

In determining the flash point, either the Elliott, Abel, Abel-Pensky or Tag Closed testers shall be used, but the Tag Closed tester (standardized by the United States Bureau of Standards) shall be authoritative in case of dispute. All tests shall be made in accordance with the methods of tests as adopted by the American Society for Testing Materials.

Storage tanks should be placed underground to obtain the greatest measure of safety. Where this cannot be done and tanks are necessarily located within the building, or above ground, such an arrangement is considered more hazardous.

Above-ground storage or supply tanks may be permitted only outside of closely built districts, or outside of fire limits.

CONSTRUCTION OF UNDERGROUND TANKS

1. *Materials of Construction.*—(a) Tanks shall be constructed of galvanized steel, basic open-hearth steel or wrought iron of a minimum gage (U. S. Standard) depending upon the capacity, as given in Tables I and II.

For liquids of 20 deg. Baumé and below, tanks may be of concrete.¹

TABLE I.

Capacity (Gallons)	Minimum Thickness of Material
1 to 560	14 gage
561 to 1,100	12 gage
1,101 to 4,000	7 gage
4,001 to 10,500	4 inch
10,501 to 20,000	1½ inch
20,001 to 30,000	2 inch

(b) In outlying districts to be prescribed by inspection departments having jurisdiction, tanks not exceeding 1100 gal. in capacity, if located 10 ft. or more from any building, may be constructed in accordance with Table II.

TABLE II

Capacity (Gallons)	Minimum Thickness of Material
1 to 30	18 gage
31 to 350	16 gage
351 to 1,100	14 gage

2. *Joints and Connections.*—All joints shall be riveted and soldered, riveted and calked, brazed, welded or made by some equally satisfactory process. Tanks shall be tight and sufficiently strong to bear without injury

¹Investigations are under way to determine the advisability of permitting the use of concrete tanks for oils above 20 deg. Baumé.

the most severe strains to which they may be subjected in practice. Shells of tanks shall be properly reinforced where connections are made and all connections made through the top of tank above the liquid level.

3. *Rust Proofing.*—All tanks shall be thoroughly coated on the outside with tar, asphaltum or other suitable rust-resisting material, dependent upon the condition of soil in which they are placed. Where soil is impregnated with materials, tanks shall also be made of heavier metal.

4. *Venting of Tanks.*—(a) An independent, permanently open galvanized iron vent terminating outside of building shall be provided for every tank.

(b) Vent openings shall be screened (30 x 30 nickel mesh or its equivalent) and shall be of sufficient area to permit proper inflow of liquid during the filling operation and in no case less than 2 in. in diameter and accessible for examination and removal; shall be provided with weatherproof hoods and terminate 12 ft. above top of fill pipe, or if tight connection is made in filling line, to a point 1 ft. above the level of the top of the highest reservoir from which the tanks may be filled and never within less than 3 ft. measured horizontally and vertically, from any window or other building opening.

Tanks of 500 gal. capacity or less may be provided with a combination fill and vent fitting so arranged that fill pipe cannot be opened without opening the vent pipe.

(c) Where a battery of tanks is installed, vent pipes may connect to a main header, but individual vent pipes shall be screened between tank and header. The header outlet shall conform to the foregoing requirements.

5. *Filling Pipe.*—Filling pipe shall be turned up so as to form a trap or seal and when installed in the vicinity of any door or other building opening, shall be as remote therefrom as possible, so as to prevent liability of flow of oil through building openings; terminal shall be outside of building in a tight, incombustible box or casting, so designed as to make access difficult by unauthorized persons.

6. *Manhole.*—Manhole covers shall be securely fastened in order to make access difficult by unauthorized persons. No manhole shall be used for filling purposes.

7. *Test Well of Gaging Device.*—See Par. 32.

8. *Setting of Tanks.*—(a) Tanks to be buried underground with top of the tanks not less than 3 ft. below the surface of the ground, and below the level of any piping to which the tanks may be connected, except that in lieu of the 3-ft. cover, tank may be buried 18 in. below the ground level and a cover of reinforced concrete at least 6 in. in thickness provided, which shall extend at least 1 ft. beyond the outline of tank in all directions; concrete slab to be set on a firm, well-tamped earth foundation. Tanks shall be securely anchored or weighted in place to prevent floating.

Where a tank cannot be entirely buried, it shall be covered over with earth to a depth of at least 3 ft.

and sloped on all sides, slopes not to be less than .3 to 1. Such cases shall also be subject to such other requirements as may be deemed necessary by the inspection department having jurisdiction. If tank cannot be set below the level of all piping to which it is connected, satisfactory arrangements shall be provided to prevent siphoning or gravity flow in case of accident to the piping.

(b) Tanks shall be set on a firm foundation and surrounded with soft earth or sand well tamped in place, or incased in concrete as outlined in Section 14 (b).

(c) When located underneath a building the tanks shall be buried with top of tanks not less than 2 ft. below the level of the floor. The floor immediately above the tanks shall be of reinforced concrete at least 9 in. in thickness, extending at least 1 ft. beyond the outline of tanks in all directions, and provided with ample means of support independent of any tank.

ABOVE-GROUND TANKS

9. *Materials of Construction.*—(a) Tanks, including top, shall be constructed of galvanized steel, basic open-hearth steel or wrought iron of a minimum gage (U. S. Standard) as specified in Tables III to VII, inclusive. No open tanks shall be used. (b) For liquids under 20 deg. Baumé, tanks may be of concrete.

TABLE III.

Horizontal or vertical tanks not over 1100-gal. capacity:

Capacity (Gallons)	Minimum Thickness of Material
1 to 30	18 gage
31 to 350	16 gage
351 to 1,100	14 gage

TABLE IV.

Horizontal tanks over 1100-gal. capacity:

Maximum Diameter	Minimum Thickness of Material	Heads
Not over 5 feet	10 gage	7 gage
5 feet to 8 feet	7 gage	$\frac{1}{2}$ inch
8 feet to 11 feet	$\frac{1}{2}$ inch	$\frac{1}{2}$ inch

TABLE V.

Vertical tanks over 1100-gal. capacity. Under 40-ft. in diameter and containing not more than 5000 gal.:

Bottom No. 8 gage
Bottom Ring No. 8 gage
Other Rings No. 10 gage
Top No. 12 gage

TABLE VI.

Under 40 ft. in diameter and containing more than 5000 gal., but not more than 10,000 gal.:

Bottom No. 8 gage
Bottom Ring No. 7 gage
Other Rings No. 8 gage
Top No. 12 gage

TABLE VII.

Other vertical tanks to be of thickness not less than indicated in the following table, the figures referring to U. S. Standard gage:

Diameter, Ft.	2nd Ring Top	3rd Ring Top	4th Ring Top	5th Ring Top	6th Ring Top	Bottom
80	10	7	7	3	0	3-0
75	10	7	7	4	1	2-0
70	10	7	7	4	1	2-0
65	10	7	7	5	1	3-0
60	10	7	7	5	2	0
55	10	7	7	6	3	1
50	10	7	7	7	4	1
45	10	7	7	7	5	3
40 and less	10	7	7	7	5	3

(c) Tanks of capacity greater than given in Table VII shall be of material sufficient in thickness to hold the contents, with a proper factor of safety. (d) No vertical tanks shall exceed 35 ft. in height. (e) Riveted joints shall have an efficiency of at least 60 per cent.

(f) The specifications for joints, connections and rust proofing shall be the same as those for underground tanks.

10. *Roofs or Tops.*—No wooden or loosely fitting metal roofs or tops shall be permitted. Roof or top shall be without unprotected openings; shall be firmly and permanently joined to the tank, and all joints made as noted previously for underground tanks.

11. *Venting of Tank.*—(a) A permanently open vent conforming to that described for underground tanks shall be provided. (b) Each above-ground tank, over 1000 gal. in capacity, shall have all manholes, vent openings, and other openings which may emit inflammable vapor provided with 30 x 30-mesh, non-corrodable wire screen, or its equivalent, so attached as to completely cover the opening and be protected against clogging. A safety relief of 1½ per cent of roof area shall be provided, or manhole covers of equal area must be kept closed by weight only, and not firmly attached. The screen on such opening may be made removable, but shall be kept normally firmly attached and shall be accessible for inspection.

12. *Setting of Tanks.*—Tanks with bottom more than 1 ft. above the ground shall have firm foundation and supports of incombustible materials, except wooden cushions. The storage of combustible material within 10 ft. of any tank is prohibited.

13. *Protection Against Lightning.*—Metal tanks shall be constructed entirely of metal including top, side and bottom; all openings shall be hermetically sealed (See Caulking of Joints), except breather vent, which shall be screened. All tanks shall be electrically grounded, by resting directly on moist earth or grounded in accordance with the requirements for lightning protection of the National Fire Protection Association. All steel work of reinforced concrete tanks shall be interconnected and grounded by an approved method.

14. *Embankments and Dikes.*—(a) In locations where above-ground tanks are liable, in case of breakage or overflow, to endanger surrounding property, each tank shall be protected by an embankment or dike. Such protection shall have a capacity of not less than one and one-half times the capacity of the tank surrounded, and to be at least 4 ft. high, but in no case higher than one-fourth the height of tank when height of tank exceeds 16 feet.

(b) Embankments or dikes to be made of earthwork or reinforced concrete. Earthwork embankments to be firmly and compactly built of good earth from which stones, vegetable matter, etc., have been removed, and to have a flat section at top of not less than 3 ft. and a slope of at least 2 to 1 on both sides

(c) Embankments or dikes shall be continuous, with no openings for piping or roadways. Piping shall preferably be laid over or under embankments; if it is necessary to install pipes through embankments concrete wing walls shall be provided. Brick or concrete steps shall be used where it is necessary to pass over.

TANKS INSIDE BUILDINGS

Inside storage is regarded as much more hazardous than outside storage. Where used the following requirements shall be rigidly applied:

15. *Setting and Heat Insulation of Tanks.*—(a) Tanks shall not be located above the lowest story, cellar or basement of building.

(b) Tanks shall be located below the level of any piping to which they may be connected, or if this is im-

practicable, satisfactory arrangements shall be made to prevent siphoning or gravity flow in case of accident to the equipment or piping.

(c) Tanks shall be set on a firm foundation and those exceeding 2500-gal. capacity shall be supported independently of the floor construction.

(d) Steel tanks shall be completely enclosed with a heat insulation of reinforced concrete not less than 12 in. in thickness, with at least a 6-in. space on sides between tank and concrete insulation filled with sand or well tamped earth, and with 12 in. of sand on top of tank, either between tank and concrete slab or above concrete slab.

(e) Concrete tanks shall be completely enclosed with a heat insulation of reinforced concrete not less than 8 in. in thickness, with at least a 6-in. space on sides between tank and concrete insulation filled with sand, or well tamped earth, except that for top of tank an insulation of 12 in. of sand without concrete covering shall be deemed sufficient.

(f) Walls of concrete tanks shall be constructed independently of and not in contact with the building walls.

16. Vents shall be installed as previously described.

LOCATION AND CAPACITY OF TANKS FOR UNDERGROUND STORAGE

17. Tanks shall preferably be located at least 50 ft. from important buildings. When this cannot be done, the limit of individual tank capacity permitted shall be dependent on the location of tanks with respect to adjacent buildings, as follows:

(a) Tanks may be of unlimited capacity if buried underneath or lower than any floor or pit of any building within 50 ft. radius of the tank. (b) Where a building having a floor or pit lower than the tank is within 40 ft. radius, the capacity of the tank must not exceed 500,000 gal. (c) Where a building having a floor or pit lower than the tank is within 30 ft. radius, the capacity of the tank must not exceed 200,000 gal. (d) Where a building having a floor or pit lower than the tank is within 25 ft. radius, the capacity of the tank must not exceed 150,000 gal. (e) Where a building having a floor or pit lower than the tank is within 20 ft. radius, the capacity of the tank must not exceed 100,000 gal. (f) Where a building having a floor or pit lower than the tank is within 10 ft. radius, the capacity of the tank must not exceed 75,000 gal. (g) If tank is within 10 ft. of any building, and the top of the tank is above the lowest floor or pit of the building, the tank shall not exceed a capacity of 50,000 gal., and must be of metal entirely enclosed in concrete.

ABOVE-GROUND STORAGE

18. (a) The relation between capacity of individual tanks and the permissible distance from other property is shown in Table VIII.

(b) For tanks of 400,000-gal. capacity or greater, a minimum distance of 175 ft. to adjoining property or nearest building may be permitted, provided that an approved type of extinguishing system is installed for the tank and covering other parts of the yard or system.

(c) For tanks permitted from 50 ft. and up to 175 ft. of building or property line, the capacity may be increased 33 per cent if the tank is provided with an approved extinguishing system.

19. *High Water.*—Tanks shall be so located as to avoid possible danger from high water.

20. *Streams Without Tide.*—When tanks are located on a stream without tide, they shall, where possible, be down stream from burnable property.

21. *Tide Water.*—On tide water, tanks shall be located, if practicable, well away from shipping districts.

STORAGE INSIDE OF BUILDINGS

22. *Permanently Set Storage Tanks Inside Buildings.*

—(a) In ordinary buildings the gross capacity of tanks shall not exceed 5000 gal. (b) In fire-resistive buildings the gross capacity of tanks shall not exceed 10,000 gal. (c) In any building, if in a fire-resistive or

TABLE VIII

Capacity of Tanks, Gallons	Minimum Distance to Line of Adjoining Property or Nearest Building (Feet)
750	5
1,500	10
3,000 or less	20
21,000 or less	25
31,000 or less	30
45,000 or less	40
64,000 or less	50
80,000 or less	60
128,000 or less	75
200,000 or less	85
266,000 or less	100
400,000 or less	150
666,000 or less	250
1,333,000 or less	300
2,666,000 or less	350

detached room cut off vertically and horizontally in an approved manner from other floors of the main building, the gross capacity of tanks shall not exceed 50,000 gal., with an individual tank capacity not exceeding 25,000 gal., provided the insulating sand specified under setting and heat insulation of tanks shall be increased to 12 in. on sides and 18 in. on top.

PIPING—GENERAL REQUIREMENTS

23. *Cross-Connections.*—Cross-connections permitting gravity flow from one tank to another except through open connections shall be prohibited. This shall not be construed as prohibiting properly gated connections through subdivisions in any individual tank.

24. *Workmanship.*—All pipe connections to tanks and other oil containing or using devices, shall be made in a substantial, workmanlike manner.

25. *Type of Material.*—All piping shall be of the standard full weight wrought iron or steel type for working pressures less than 100 lb.; for working pressures in excess of 100 lb., extra heavy pipe and fittings shall be used. No pipe less than $\frac{1}{2}$ in. internal diameter will be permitted.

26. *Installation.*—Piping shall be run as directly without sags, and so laid that where possible pipes pitch toward the supply tank without traps; provision shall be made for expansion, contraction, jarring and vibration.

27. *Tests.*—Piping for systems with working pressures under 100 lb. after installation shall be tested and proved tight at a pressure of not less than 150 lb.; where working pressures exceed 100 lb., piping shall be tested and proved tight at a pressure 50 per cent in excess of the working pressure.

28. *Unions.*—Union, if used in place of right and left couplings, shall be of an approved type.

29. *Protection to Piping.*—(a) Piping between any separated oil containing or using parts of the equipment shall be as far as practicable laid outside of the building underground, and properly protected against corrosive action; if necessarily inside it shall preferably be laid in a trench with proper metal cover; if on floor or subject to mechanical injury it shall be protected.

(b) Pipes leading to the surface of the ground or above the floor, particularly risers to furnaces, shall be cased or jacketed when necessary to prevent loosening or breakage.

(c) Fill and vent pipes shall be protected in a substantial manner against mechanical injury.

30. *Outside Piping.*—(a) All outside piping shall be laid in solid earth, or in a trench. Oil pipes shall not be located near, nor in the same trench with other piping, excepting steam lines for heating. Propping the pipes on wooden blocks shall be avoided. (b) Openings for pipe through outside walls below the ground level shall be made oil-tight and securely packed with flexible material.

31. *Valves.*—(a) All valves shall be of an approved type. (b) Shut-off valves shall be provided on both sides of any strainer which may be installed in pipe lines; in discharge and suction lines to pumps; in discharge and return lines to any tank, as near as practicable, and in branch lines near burners. (c) A check valve of an approved type shall be installed in each air line near the burner. (d) A pressure relief valve shall be installed in supply lines to burners and so arranged as to return surplus oil to supply tank. (e) The use of automatic shut-off valves for the oil supply is recommended.

32. *Oil Level Indicating Device.*—A test well or gaging device shall be installed, and so designed as to prevent the escape of oil or vapor within the building at any time. Top of well shall be sealed and, where located outside of building, kept locked when not in use.

33. *Strainers.*—Suitable strainers shall be installed in the suction line. Large basket strainers are recommended in the receiving or filling line of storage tank to remove dirt and foreign matter.

HEATING

34. *Heating of Tanks.*—(a) Where it is necessary to heat oil in storage tanks in order to handle it, the oil shall not be heated to a temperature higher than 40 deg. F. below the flash point, closed cup. (b) Heating shall be done by means of properly installed coils within the tank, using only steam or water. Thermostatic control and thermometer shall be provided for all heating devices.

35. *Heaters, Other Than Those for Tanks.*—(a) Heaters shall be of substantial construction; all joints shall be made oil-tight. (b) Only steam or water shall be used for heating. (c) Heater shall be by-passed so that in warm weather it will not be under constant pressure while not in use.

FUEL OIL BURNERS

36. (a) The burner mechanism shall be so designed as to not enlarge the orifice, and so that the needle valve cannot be unscrewed and removed in operating.

PUMPING SYSTEMS

37. Oil shall be pumped from tank to burners. Systems where burners are supplied by gravity, or pressure on tanks are prohibited.

38. *Pumps.*—(a) Pumps shall be in duplicate, of an approved design, and secure against leaks. (b) They shall be located in a room cut off from oil-burning devices and provided with entrance which can be reached without passing through room where burners are located; if this is not practicable, provision shall be made for remote control. (c) Pumps used in connection with

the supply and discharge of storage tanks shall be located outside the tank or embankment walls, and at such a point that they will be accessible at all times, even if the oil in the tank or reservoir should be on fire.

OBJECTIONS TO THE REGULATIONS

The following are the objections that have so far come to the attention of the American Petroleum Institute.

In commenting on these criticisms, the Institute desires that the reasons for asking for any changes should be clearly stated, as it is concerned with both the practical side of the question and the economic effect these regulations are likely to have.

Flash Point 150 Deg. F.—This is too high, and while not necessarily arrived at in consideration of the U. S. Navy fuel oil specifications, where altogether different conditions are met with, the effect is the same. In oil fields and in many industrial establishments where fuel oil has been in constant use for a great many years oils of a much lower flash point have been used without accident and fire arising from the point of flash. It is clear that oil having a flash point of 100 deg. F. is safer than an oil that flashes at 30 deg. F.; but above atmospheric temperature, for storage purposes an oil that flashes at 200 deg. F. is no more dangerous than that which flashes at 600 deg. F. In the same sense, if an oil is well above atmospheric temperature, it is just as safe with its flash point at say 135 deg. F. as it would be at 150 deg. F. The flash point of oils is most generally accepted as the index of the fire hazard because it is not until the oil has been heated to its ignition temperature (i.e., fire point) that explosion takes place in the body of the oil. Oil cannot ignite at the temperature of its flash point, and therefore, if suitable provision for venting is made, such small volumes of gases as may be given off before the oil reaches the temperature of its fire point should vent themselves, and cannot cause a conflagration of the oil in the tank. A tank that is not a still and from which combustible material is kept is perfectly safe. A flash point of 135 deg. F. has been suggested, which for all practical purposes is contended to be as safe as 150 deg. F., and is a great deal easier to be met with by fuel oil producers all over the country. To set 150 deg. F. as the minimum flash point is to exclude oils of lower flash, and we are desirous of knowing just what effect this would have upon the industry.

Par. 1 (a).—Question has arisen as to whether there is preference for the use of the Birmingham gage over that of the U. S. Standard. Galvanized steel would be unnecessarily expensive, since fuel oil would not have a corrosive action upon ungalvanized steel, and painting of tanks should afford every protection for exterior.

Par. 2. "All connections made through top of tank above liquid level."—Bottom connections from storage tanks should be permitted. The statement of the chairman of the Committee on Inflammable Liquids that permission may be secured for such bottom connections is not in itself sufficient and the regulations should properly provide for this. It is argued that it is impossible to empty tanks over 12 to 15 ft. in height from connections made from top above the liquid level.

Par. 9.—Provision should be made that rectangular be rewritten and the burying of tanks be reduced to less than 3 ft. where there is no live load. It is also suggested that a tank may be buried 12 in. below the ground level instead of 18 inches.

Par. 9.—Provision should be made that rectangular tanks of suitable strength shall be permitted.

Par. 9 (a).—Change U. S. Standard to Birmingham. See also Par. 1 (a).

Tables III to VII.—A large refiner states that "regulations should permit the use of metal tanks without limits to dimensions so long as an established factor of safety is observed. Therefore we recommend that all dimensions of tanks be eliminated."

Par. 9 (d).—Some vertical tanks are 48 ft. high. If you have any objection to 35 ft. we would like to know what has been your experience in this respect and what you would suggest as practicable.

Par. 9 (e).—It has been suggested that 60 per cent be changed to 50 per cent and that the following be added: "but a less efficiency will be allowed if the factor of safety of the tank is 3 to 6."

Par. 10. "Roof of top. . . . shall be firmly and permanently joined to the tank."—If anything goes wrong the roofs cannot be lifted. It should be noted in this paragraph in connection with paragraph 2 that bottom connections including bleeders are not permitted.

Par. 14.—Embankments or dikes are without doubt advisable where crude oil is stored, but it has not been the practice in many quarters to provide them for tanks holding fuel oil distillates. This provision would not necessarily insure protection, since they would become filled with rain and the water become stagnant, polluted, prejudicial to health, and a breeding place of mosquitoes, while if free of water in time of fire they would soon become filled with water that may be used in extinguishing fire. Moreover, these dikes, if not filled with water, would be in the nature of "catch-alls" for waste paper, etc. If you think this provision will prove an unnecessary burden it would be advisable to state what has been the general practice in this respect.

Specifications for Concrete Tanks.—This section has been set aside pending the outcome of the test to be conducted by the Committee on Concrete Tanks of the American Concrete Institute, which will probably cover a period of two months. The results of these tests are to be submitted before the convention of the American Concrete Institute to be held in Chicago next February, but without doubt the National Fire Protection Association will be guided by these tests in fixing specifications upon concrete tanks before that time.

Moreover, the provision that "for liquids of 20 deg. Baumé and below tanks may be of concrete"—Par. 1 (a) and 9 (b)—should also be set aside until the tests have been completed. It is well known that oils of lighter gravity than 20 deg. Baumé have been stored successfully in concrete tanks.

Pars. 17 and 18.—It is contended that distance of tanks from buildings cannot be economically determined by a set rule, as hazards and practicability of each location must have special consideration.

Par. 22.—It is the practice to maintain on hand 14 days' supply of coal. Office buildings are now using as much as 4000 to 5000 gal. of fuel oil daily, and it is necessary that as much as from 40,000 to 50,000 gal. be kept in storage during cold weather. If tanks are properly designed and built, is there any particular reason why special provisions should be made for special fire-resistant rooms when as much as 50,000 gal. are to be kept in storage? What has been the general practice?

Par. 34 (a).—This provision has the effect of stating that the flash point is not a measure of the hazard, and seems unduly severe, for in practice fuel oil in storage is frequently heated to a temperature higher than 40 deg. below its flash point.

Par. 38 (a).—This has been much disputed. It does not give consideration to those smaller installations where the duplicate pump is not only economically a burden but is unnecessary because cessation in operation permits time for cleaning and repairing.

Par. 38 (b).—This paragraph requiring pumps to be located in a room cut off from oil-burning devices has been strongly objected to. What is your attitude toward this provision?

Great Future Predicted for the Anhinga Fiber Industry

The plant known as anhinga is a native of the State of Para, Brazil, and it is declared that this State alone is capable of producing 100,000 tons annually for export.

The anhinga constitutes the raw material from which cellulose for the manufacture of linen paper is obtained. The fibers may also be transformed by a chemical process into an artificial cotton fiber. The fact that this fiber does not decay gives it an advantage over that obtained from analogous plants. The anhinga grows along the banks of all the rivers of Para, which have a slow current, permitting a soft bed of mud for their roots. In 1908 the Commercial Association of Para received a letter from a paper factory as to the possibilities of obtaining this fiber in large quantities, but at the time the association was unable to find anyone to exploit the industry, because of the large and easily acquired profits afforded by the rubber industry. However, experiments were made last year with excellent results, and those interested in the new industry have recommended that abandoned sugar mills be fitted up for the treatment of the fiber. A mill already in operation is producing 600 kilos daily. The price of the fiber at Para is 300 to 350 reis per kilo. It is stated that the head of the Para State Chemical Laboratory has discovered a new process for dissolving the fibers, transforming them into very fine, white fibers, like cotton fiber of prime quality. Moreover their structure is superior to that of the cotton fiber, since the lines are straight and parallel.

* The Chemical Industry in China

Ho Hsin Smelting Works, capitalized at approximately \$550,000, has commenced operations at Pootung and aims to become one of the leading steel works in China. Its daily output at the time of the latest available report was 10 tons of pig iron. When the plant is completed the output will be 40 tons daily.

Under the direction of Japanese chemists certain chemical products such as caustic soda, cresol, stearin and soaps have been manufactured in Kwantung during the war. The raw materials were brought from Manchuria.

A committee of chemical investigation reports that there is in Manchuria a great abundance of raw materials suitable for use in the chemical industry, awaiting only active participation of capital to yield large returns.

More than 20 cotton spinning and weaving mills are now being operated at Shanghai. British, Japanese and Chinese interests are predominant. Large tracts of land at Yangtzepoo and Pootung have been purchased by Japanese interests and extensive mills are being erected. It is reported also that a number of modern office buildings requiring building materials of many types are about to be erected in Shanghai.

Patent Rights and Remedies

BY CHESLA C. SHERLOCK

BEFORE a patentee can seek damages for an infringement of his patent or invention, he must know just what his rights are under the law and what constitutes an infringement.

It is not necessary, for a patent right to be violated, for the infringing device to be identical with the patented article in form and appearance. A long line of cases holds to the view that proof of adoption of the substance of the patent is sufficient to show infringement.

"In one sense," said Mr. Justice Brown, "it may be said that no device can be adjudged an infringement that does not substantially correspond with the patent. But another construction, which would limit these words to the exact mechanism described in the patent, would be so obviously unjust that no court could be expected to adopt it."

However, there are upwards of fifty cases decided by the United States courts in which it is held that the patentee is to be protected only in respect to the precise device which he has claimed and described in his patent. And another long line of cases is authority for the statement that a machine or process which is substantially different is no infringement.

WHAT IS AN INFRINGEMENT?

In *Winana v. Denmead*, 14 U. S. (L. ed.), 717, and *Werner v. King*, 96 U. S., 218, it was held that "when form and substance are inseparable, it is enough to look at the form only. When they are separable, where the whole substance of the invention may be copied in a different form, it is said to be the duty of the courts to look through the form for the substance of the invention—for that which entitled the inventor to his patent, and which the patent was designed to secure; where that is found it is an infringement; and it is not a defense that it is embodied in a form not described and in terms claimed by the patentee."

Nor will the law permit the infringer to escape punishment where he has adopted a substantial equivalent of the patented article, for the substantial equivalent of a thing, in the sense of the patent law, is the same as the thing itself; so that if two devices do the same work, in substantially the same way, and accomplish substantially the same result, they are the same even though they differ in name, form and shape.

HOW PATENTEE MAY ASSERT RIGHTS

Having this brief statement of what will ordinarily amount to infringement, we are now able to pass on to a consideration of the more important phase of the subject, namely, the manner in which the patentee or those holding under him may assert their rights under the patent.

In the first place, it must be kept in mind that the inventor has no exclusive right to his invention until he has acquired a patent. It is the patent that conveys these rights and not the invention, and no suit can be maintained without such patent.

The very first obligation on the part of one bringing a suit for infringement of a patent is that he must allege that he is the original inventor and patentee, or that he holds under a patent so taken out. This does

not mean that in the absence of a patent an inventor has no rights in his invention, but it simply means that the rights hereinafter mentioned do not belong to any but those who may show that they hold under a patent. The inventor certainly has a property right in his invention, and this property right will be enforced by a court of equity.

The suit must be brought in the name of all parties interested in the patent at the time it was infringed, whether the patentee, assignee, grantee, or all of them jointly.

It is essential, in order to assert the rights under a patent, to mark the patented article with the date thereof, and where this is impracticable to note it on the wrapper or carton. It is also necessary to give notice to the infringer that he has infringed the patented device, and it has been held that neglect to place the date of the patent on the article will not defeat the rights of the patentee provided he has given notice of infringement to the infringer, as it accomplishes the same result.

As to how the infringement is determined by the courts and juries, there are many rules and practices. In the case of machinery, for instance, the two machines are set up side by side and the question is determined by comparison. The burden of proof is upon the plaintiff or patentee, unless the defendant specifically admits that he has infringed the patented article.

RULE ON RECOVERY OF DAMAGES

As a rule, the patentee is entitled to recover such damages as he may show that he is entitled to. There has been a great deal of discussion as to whether royalties on the infringing article made and sold were not the proper basis of damage for the patentee.

Mr. Justice Field has said: "In order that a royalty may be accepted as a measure for damages against an infringer who is a stranger to the license establishing it, it must be paid or secured before the infringement complained of; it must be paid by such a number of persons as to indicate a general acquiescence in its reasonableness by those who have occasion to use the invention; and it must be uniform at all places where the licenses are issued."

Where the patent has been infringed before a royalty has been established, the patentee may show what a reasonable royalty would have been and, upon such showing, use it for a measure of damages against the infringer.

It is also a right of the patentee, upon a showing of infringement, to have an accounting of the business done by the infringer, especially an accounting of the profits of the infringing device, and, upon a showing of them, recover all of the profit made by the infringing device.

However, he cannot hold the infringer for profits which were not made, and in this case his remedy is for damages in such amount as he is able to set up and recover.

We have found, then, that a substantial infringement of the patented device is sufficient to constitute infringement in the sense of the patent law, and that the patentee may recover profits, if there have been any; or damages, or a royalty on the articles manufactured, and where no royalty was established, a reasonable royalty on the device.

Phosphatic Coatings for Rust Proofing Iron and Steel

BY L. E. ECKELMANN

AMONG the most successful and comparatively recent developments in the non-electrolytic rust proofing of iron and steel is that employing phosphatic iron as a protective coating. All of the older processes of rust prevention, such as the Browning, Bower-Barff and others similar in principle, though giving moderately good coatings and, in the case of the Browning method, beautifully colored and lasting finishes, were uneconomical of time, expenditure of heat, and in some cases required a multiplicity of operations. The personal skill and experience of the operator were also most important factors in many of these processes where high temperatures, muffles and combinations of fused salts were used.

Recent phosphatic rust proofing differs from other methods in that the dimensions or sharpness of finely machined edges and surfaces of the articles are not appreciably altered. Due to the low temperatures used, the physical properties of tempered steel are in no way affected, and magnets so treated retain their magnetic force. Even very fine springs do not have their elasticity impaired. Fig. 1 is an illustration showing the remarkable adhesion or molecular bonding of the phosphatic coatings. On the other hand, dental needles having points so fine (0.003 in.) that a slight corrosion ruins them completely are successfully protected by phosphatic coatings without injuring the elasticity of the needles or affecting the delicate barbs covering their surfaces.

COSLETT'S PROCESS

Rust proofing is effected simply by immersion of the clean objects in a hot solution for periods of one to three hours. The deposition of the coating depends upon the action of a solution of iron phosphates in weak H_3PO_4 on a metallic base, such as iron. Phosphoric acid solutions will dissolve ferrous phosphate within certain

This reaction was the basis of the process developed by Coslett in 1907, its later commercial adaptation operating as follows: Ferrous phosphate made by mixing iron filings with concentrated H_3PO_4 , sufficient to form a semi-fluid paste was added to weak boiling phosphoric acid. Iron or steel articles were immersed in this boiling solution for three or four hours, and when removed were covered with a rust-resisting light gray deposit of basic ferrous phosphate. The difficulty of obtaining uniform coatings, the great amount of suspended salt adhering to the work—in some cases incorporating itself with the actual coating and increasing the dimensions of the articles—the consequent necessity of rinsing the work after treatment, and the non-uniformity of the finish, all contributed to the slow adaptation of this process until these troublesome features could be eliminated.

PARKERIZING

Messrs. Allen and Richards were mainly responsible for changes in the Coslett process, which made its present modification one of the most simple methods of rust prevention. Their patented modification in use today is known as "Parkerizing." The old Coslett solution was modified by the addition of an oxidizing agent such as MnO , to a 0.75 per cent solution of H_3PO_4 , containing ferrous phosphate, this salt being partly oxidized to the ferric state after continued agitation and boiling. This last action is necessary to complete the partial oxidation of the ferrous salt, the correct proportion between the phosphates being 3 ferrous to 1 ferric. The formation of the coating, a basic ferrous-ferric phosphate, is similar in action to the Coslett reaction mentioned above. It has been found lately that part of the MnO may be replaced by air, also that in the latter case the action of the MnO can be considered as partly catalytic.¹ In the latter method of oxidation, the method of aeration presents a practical problem, since the finish of the work will be affected if the objects processed are of complicated form, and air be trapped and held in contact at any point.

NATURE OF COATING

The coating on iron or steel articles after removal from this phosphoric solution is of a uniform dark gray color, varying in intensity of shade according to the surfacing treatment the articles had previously received. In common with all chemical methods for metal coloring, the shadings obtained with phosphatic coatings are dependent on the previous treatment of the metal surfaces, such as sand blasting, tumbling, rubbing, etc. The choice of pickling solutions is also quite important. It is very interesting to note that while both the ferrous and ferric phosphates are light colored salts, the resulting ferrous-ferric phosphate is grayish black. There does not seem to be any definite formula for this compound; it may also be considered a mixture of basic phosphates. During the oxidation MnO , will break down to manganese phosphate, which also possesses rust-proofing qualities.

Processed materials, when dry, are dipped in a paraffine oil mixture, this treatment changing the dark gray coating to a deep black.

Phosphatic rust proofing is particularly adapted for the treatment of tools, typewriter parts, ordnance, motor parts, in fact for many things where rust should be prevented and an attractive finish is desired. In sub-

FIG. 1. PHOSPHORIC COATING IS NOT SPLIT OFF BY LARGE DEFORMATION

(On left—Before compression. On right—After compression. Both actual size)

limits in direct proportion to the concentration of the acid present. If any base or metal be added—for example, iron—capable of entering into combination with the free acid present in such a solution, the formation of ferrous phosphate on the metallic surfaces will precipitate this salt back on the iron at the point of solution. The already saturated condition of the iron phosphate solution will naturally aid the precipitation when more of this compound is formed. The action proceeds with the evolution of hydrogen until no more elemental iron is exposed, the article being then completely coated with a basic iron phosphate.

¹See U. S. Pat. No. 1,248,053.

marine mine cases used during the war, it was found that barnacles would not adhere to them when previously rust proofed by the above methods. Articles can be processed partly assembled, as the size of the parts will not be affected. Another peculiar phenomenon exhibited by the phosphatic coatings is the stoppage or filling of pores in defective castings, the sealing of these fissures holding even when subjected to considerable pressure.

EQUIPMENT OF RUST-PROOFING UNIT

The main equipment of a moderate-sized unit consists of one 1000-gal. air jacketed, steam-heated, welded tank, four 450-gal. wooden tanks, a sand tumbler, boiler, and oil draining pans. The four wooden tanks are arranged in line, somewhat as shown in Figs. 2 and 3, two being heated with steam coils, and the other two are used for rinsing with jets. These tanks contain the following solutions in the order named: Caustic cleaner, rinse, pickle, rinse. The steam inlets in the two rinsing tanks provide the circulation by condensation, outlets being at the top. A 30-hp. boiler should give sufficient steam without need of preheating the feed water.

It is important, when planning, to arrange the cleaning and processing tanks, sand tumblers and other units in routine order. An overhead track passing over the different tanks is necessary, preferably extended at the ends to stack accumulated work. The writer advises the use of a double set of chain hoists. This will facilitate the rapid transference of work, which is carried in this case in steel baskets containing perhaps 450 assembled metal stampings, weighing about 375 pounds. Transference work from wooden pickling baskets to steel ones for the acid dip could in certain cases be eliminated by using lead- or tin-coated steel baskets.

Concentrated H_2PO_4 , solutions of ferrous phosphate, powdered MnO_2 , the ordinary pickling acids, soda, potash, oil- and grease-removing cleaners, and dipping oil are the only materials used. The processing acid is supplied by the licensors of the process.

OPERATION OF PROCESS

The iron or steel articles are freed from oil and grease by immersion for about twenty minutes in a solution of caustic soda or some patent cleaner—some of these cleaners easily removing mineral oils. Cleaning solutions should be over 200 deg. F. for best results. The work is now thoroughly rinsed in hot or boiling water, to dissolve any soaps formed in the cleaner, and when free of alkali passed into a 5 per cent H_2SO_4 pickle containing 1 oz. sodium bisulphite per gal. The decomposition of this salt will liberate SO_2 , and if the pickling solution is kept below 150 deg. F., the SO_2 will be retained in sufficient quantity to act upon the work being cleaned. Black scale often present on iron, mainly Fe_3O_4 , is quite insoluble, and can only be removed by excessive pickling, which is destructive to assembled or riveted work. The dissolved SO_2 will partly reduce the black scale to lower oxides, consequently facilitating solution and cleaning the metallic surfaces. When clean, which requires about 20 min., the work is again thoroughly rinsed in boiling water, to remove all acid and iron sulphates, then dried, sand tumbled or rubbed, and passed into the phosphate tank.

It is essential at this point that all articles be free from any adhering sulphates, as this radical is harmful to the phosphate solution. Some will always remain on the work, particularly when many parts are massed and

treated together, and the last traces must be removed by rubbing or tumbling with sand. Sulphates not only affect the action of the rust-proofing solution but cause the formation of a rough, glistening coating. This is a coarse crystalline phosphate of iron, apparently growing from nuclei at points previously covered with sulphates. The size of the surface crystals seems to depend not only on the amount of metallic sulphate present, but upon unequal acidity over the surfaces of the object treated.

The writer has been able to eliminate the troublesome sanding operation in certain cases where the objects were of a shape permitting easy draining. After leaving the pickle the parts were immersed in limewater, and the precipitated calcium sulphate removed by agitation in a hot-water rinse. When this procedure is possible much time can be saved. It is a point where further development is possible, and a closer study of the effect of the different pickling acids on the processing solution and finish is necessary.

When metal is free from rust or scale, it can be sent to the phosphoric tank immediately after removing the grease and oil if a sand rub be substituted for the pickle. Clean, newly machined parts and stampings can be treated this way, the oil being removed with an organic solvent such as carbon tetrachloride. Unless the previous treatment of the steel or iron is known, this last procedure is not recommended.

When clean the work is transferred from the wooden crates used for pickling to steel baskets used in the rust-

FIGS. 2 AND 3. AN INSTALLATION OF 10-TON DAILY CAPACITY

proofing bath. When the sulphates are removed by lime-water the time consumed in transferring the articles can be saved by using lead coated baskets of the largest possible mesh.

Processing solution is made by mixing the phosphoric acid-iron phosphate mixture (sold under the trade name "Hyroncid") and manganese dioxide in the proportions

FIG. 4. EXPOSURE TEST OF SHEET PARTLY COVERED WITH PHOSPHATIC COVERING

of 4 pints acid and 2 lb. MnO_2 to each gallon of water, thoroughly mixing and boiling. Prolonged boiling for 12 hours is necessary when the solution is first made up, to insure the correlation of the different variables, such as acidity, ferrous and ferric iron. Continuous circulation of the solution is effected by proper construction of the tank, which should be provided with side heating coils and deflection vanes. Sludge forming from MnO_2 after the tank has been in use for some time is prevented from coming in contact with the work by baffle plates placed a certain distance from the bottom of the tank.

The articles are immersed from one to two and a half hours at 210 to 212 deg. F. When the evolution of hydrogen has ceased, the work is removed, dried, dipped in a paraffine oil mixture, and set in racks or pans to drain. Between batches it is advisable to boil the solution for an hour or two, as this improves its action.

Care must be taken to place the work so that it presents the least resistance to the flow induced by the heating coils and vanes in the tank.

CHEMICAL CONTROL

Ten cc. of the rust-proofing solution should be equivalent to 14.5 cc. N 10 NaOH for good results. Acidity running up to 18 cc. N 10 NaOH is not harmful, but higher amounts will have a pickling action on the work.

Twenty-five cc. of the solution should contain from 0.0236 to 0.0335 g. ferrous iron, and from 0.0019 to 0.00559 ferric iron. This is titrated with N 10 $KMnO_4$ in the usual manner—for more accurate readings N/20 $KMnO_4$ should be used. Correct correlation of acidity, ferrous and ferric iron is essential, and must be closely watched and controlled.

For convenience in operation, the acidity of the rust-proofing bath is expressed in "points of strength," 1 cc. N 10 NaOH being taken as one point. The depletion of the solution after each batch of work is coated will vary slightly from one to two and one-half "points." Acid and MnO_2 are added, the amounts and proportions per gallon given above being equivalent to one point of strength.

RESULTS OF PHOSPHATIZING

Objects of iron and steel treated by the above process are very resistant to rust, withstanding exposure, saline atmospheres or laboratory fumes to a large degree, and

testing very satisfactorily under the salt spray.* (See Fig. 4.)

Iron and steel protected with phosphatic coatings are not so resistant to wear and abuse as sherardized or galvanized metal. Surfacing composed mainly of Fe_3O_4 , produced by the Bower-Barff and similar processes are more resistant to acids and bluer in color. However, phosphatic rust proofing is considerably cheaper than any other well known rust-proofing process in use today, the simplicity of treatment and uniformity being important factors in its favor.

New York, N. Y.

Synopsis of Recent Chemical and Metallurgical Literature

War-Time Ferrous Metallurgy in Germany.—In the *Iron and Coal Trades Review* for Sept. 12 and 19, 1919, are printed abstracts of reports of the Commission appointed to examine the iron and steel works in the war zone. They present a good review of the present status of the steel plants in Lorraine, Belgium, France, Luxemburg, and the occupied portions of Germany. A significant quotation regarding the metallurgical practice in the works under control of the Central Empires follows:

"A remarkable ingenuity was displayed in German works by the technical and engineering staffs in devising substitutes for materials which were unobtainable owing to war conditions. Thus the deficiency in manganese ores was partly made up by the use of low-grade manganese ores and old manganiferous slags. The slags from the Westphalian blast-furnaces contained as much as 14 per cent of manganese, a large part of which could be recovered by re-smelting. The process was wasteful of fuel, and would not be profitable in normal circumstances, but in the emergency which arose this source of manganese proved to be most valuable. Calcium carbide was also substituted in some cases for ferromanganese in the manufacture of steel. But no evidence was forthcoming of any important technical developments in iron- and steel-making during the war; nor did the Commission find evidence of any large extensions to works having been made. The production of iron and steel in Germany being largely in excess of normal requirements in peace time, there was a sufficiency of output to meet war demands without any great extensions, such as were necessary in England. Indeed, when war broke out, it was at first impossible to dispose of the whole German production of steel, and a number of furnaces were put out. At a later stage of the war, when the demand for munition steel became pressing, the then existing shortage of labor made it difficult to meet this demand by the ordinary methods, and the difficulty was met to a considerable extent by the melting down of scrap obtained in great quantity by breaking up machinery and plants in the Belgian and French areas under German occupation. The breaking up of valuable machinery and plants in Belgian and French works, however, served another purpose, namely, the removal of competition in the years immediately following the conclusion of peace; and that this was the main object aimed at was evidenced by the systematic way in which in most cases

*General Electric Bulletin, No. 48,926.

the most vital parts of the plant were selected for destruction, even when large quantities of easily accessible material were available in other parts of the works."

Hydrogen in the Ozone Form.—Closely allied to the practical work which has been carried on during the last two years in the reduction of gases of the atmosphere, oxygen, nitrogen and helium, and the manufacture of hydrogen and ozone, the more recent research and study of Prof. GERALD L. WENDT, of Chicago University, on the ozone form of hydrogen proves most interesting. Detailed accounts of his research are printed in the *Proceedings of the American Academy* as well as those of the American Chemical Society. The following paragraphs cover a brief abstract of the more complete report.

It is believed that hydrogen atoms, although possessed of single valences, unite to form a molecule of a weight 3, with seemingly the same relation to the hydrogen molecule as ozone has to the oxygen molecule. The active qualities of this new form differ from those of atomic hydrogen.

This is without doubt the same gas discovered to be present in a hydrogen discharge tube by Sir J. J. Thompson in 1912 and called by him X_2 . In his experiments he found it combined with oxygen under action of light, was destroyed by sparking with oxygen or heating with copper oxide. It stood high temperatures without disintegration. No new spectrum was obtained with it.

Dr. Wendt, working with William Duane,¹ in 1914, produced chemically active hydrogen with alpha rays from radium, accompanied by a distinct contraction of the gas. The new gas formed H_2S with sulphur; reduced neutral permanganate solution to give manganese dioxide precipitate; decolorized acid permanganate, giving a manganous salt; reduced arsenic to arsine and phosphorus to phosphine; and gave a yellow compound with metallic mercury, probably a hydride, which decomposed on heating. Separation by an electrostatic field, 1000 volts per cm., proved these activities were not due to charged molecules or ions. The active gas is unstable, breaking down to the inactive molecule in a few minutes. In a temperature of liquid air the activity is destroyed either by condensation or disintegration to ordinary H_2 .

The recent work of Lind² and Usher,³ the latter in Ramsay's laboratory, has confirmed that the molecule of this gas is larger than H_2 . Langmuir⁴ has prepared an active form of monatomic hydrogen which is distinct from H_2 in that it will not pass through a plug of glass wool, being strongly adsorbed, and in that it does not exist except at the very highest vacua. The ozone form will on the contrary pass through long layers of glass wool and exists for some time at atmospheric pressure.

J. J. Thompson⁵ by photographic method and Dempster⁶ by electrical measurement have both shown the presence of H_2 in a tube of H_2 under electric discharge at high vacuum, and at pressures of 0.05 mm. the latter has shown that H_2 predominates.

Dr. Wendt makes this ozone form of hydrogen by

passing ordinary H_2 through a Geissler tube. The absence of hydrogen ions in the product is shown by passing through a sensitive emanation electroscope. This is done over a period of many hours where the instrument is sensitive to the detection of 10 to 12 curie of radium emanation, with ease, and no ions are evidenced.

The H_2 molecule is not in accordance with the present theories of valence, although it has been proved consistent with Bohr's model of the hydrogen atom. "Indeed," as Prof. Wendt says, "it is probably only the injunction due to the valence theory which has prevented the observation of this variety of hydrogen at a much earlier time than the present."

Recent Chemical and Metallurgical Patents

Australian Patents

Complete specifications of Australian patents may be ordered from the Government Printer, Melbourne, one shilling each.

Recovering Fats and Oils.—To recover fats and oils from trade waste liquors, the saponaceous products are broken up by chlorine without agitation, the fatty matter being liberated from the alkaline base. The liquors are allowed to settle and then removed to another tank, where chlorine is forced into the inflowing stream by means of a jet of compressed air. (Australian Patent 6886, A. J. DE BAEVE, New South Wales; April 15, 1919.)

Electrodeposition of Zinc.—To minimize the deleterious effect of small quantities of cobalt in a zinc sulphate electrolyte, glue is added to the liquid either before or after passing into the cells. (Australian Patent 7190, R. H. STEVENS; assigned to Electrolytic Zinc Co. of Australasia Proprietary, Ltd., Tasmania; May 6, 1919.)

Dissolving and Breaking Down Shellac.—To prepare a solution of shellac for stiffening felt hats and like purposes, 4 lb. of soda is dissolved in 4 gal. of water in a steam-jacketed pan, after which 5 lb. of resin and 20 lb. of shellac are successively added and the mixture is gently boiled for 2 or 3 hours. Six lb. of salt and 3 lb. of soda each dissolved in 3 gal. of water are then added to the mixture, which is finally boiled for 2 hours. This mixture may be broken down by slowly stirring in 8 or 10 gal. of cold water, and for treating soft felt hats 1 lb. of linseed oil is substituted for the resin, while for hard felt hats about 10 lb. of resin may be used. (Australian Patent 7624, T. MACKENZIE, South Australia; May 6, 1919.)

Liquid Fuel.—To manufacture a liquid fuel which is suitable for internal combustion engines, alcohol is partially etheralized by making it bubble, at a temperature of distillation of 100 to 150 deg. C., through a mixture consisting of 9 parts of sulphuric acid and 5 parts of alcohol. The resultant distillate is rectified and mixed with 10 to 40 per cent of alcohol and 5 to 50 per cent of a suitable hydrocarbon oil to produce a fuel mixture having a specific gravity of 0.730 to 0.780. (Australian Patent 8816, A. DE FEO LOPEZ, Argentina; June 10, 1919.)

Manufacturing Oil Pastes.—To obviate drying the material when preparing oil pastes, such as white

²S. C. Lind, *J. Am. Chem. Soc.*, vol. 41, p. 545 (1919).

³F. L. Usher, *J. Chem. Soc.*, vol. 97, p. 400 (1909).

⁴Irving Langmuir, *J. Am. Chem. Soc.*, vol. 34, pp. 860, 1310 (1912); vol. 36, p. 1708 (1914); vol. 37, p. 417 (1915).

⁵Rays of Positive Electricity, Longmans (1919).

⁶A. J. Dempster, *Phil. Mag.*, vol. 31, pp. 438-443 (1916).

lead from lead precipitates, a predetermined quantity of borate of manganese, not exceeding 0.5 per cent, is added to the wet precipitate, after which oil is added and the mass is subjected to thorough mechanical working and mixing to expel the water and cause the oil to combine with the precipitate. (Australian Patent 8323, H. P. FLETCHER, New South Wales; July 8, 1919.)

Paint for Tropical Climates.—A paint which consists of 43.5 parts of precipitated lead carbonate, 6.5 parts of finely powdered dolomite, 36.5 parts of precipitated zinc hydroxide, 3 parts of infusorial earth, 4 parts of finely precipitated aluminum hydroxide, 0.5 parts of cobalt acetate, and 6 parts of precipitated calcium sulphate, which are dehydrated and mixed with 6 parts of polymerized linseed oil, 4 parts of refined perilla oil, 6.5 parts of refined linseed oil, and 1.5 parts of Chinese tung oil. (Australian Patent 8833, E. MAJOR and J. A. MAJOR, New South Wales; July 22, 1919.)

Hydrocarbon Cement.—A cement for building, paving, etc., in which pitch, tar, or other aromatic hydrocarbon having a specific gravity of not less than 1.1 is brought to a temperature of 120 to 180 deg. C., and mixed with from one to four times its volume of powdered metallic sulphates, such as calcium or magnesium sulphate. In a modification, the mixture is formed under pressure in a closed vessel to raise the boiling temperature, the volatile matter produced being utilized as fuel for the process. (Australian Patent 7487, W. S. BARRIE and L. CHADWICK, Queensland; July 29, 1919.)

Canadian Patents

For full specification address Commissioner of Patents,
Ottawa, Canada

Leather Manufacture.—A process of treating leather which consists in covering the leather with a thin coating of oil heated to a temperature of approximately 150 deg. F., then allowing the oil to remain in contact with the leather for approximately 12 hours and until the temperature of the leather has cooled to approximately 80 deg. F., then applying a second coating of oil heated to approximately 150 deg. F., and again allowing the leather and oil to remain in contact and cool to a temperature of approximately 80 deg. F. for another 12-hr. period, and repeating the alternate heating and cooling processes until 5 or 6 coatings have been applied. (Canadian Patent 189,958, ALFRED J. HAWKINS, Montreal, Quebec; April 29, 1919.)

Potassium Extraction.—A process of producing a soluble salt of an alkali metal, which consists in treating a silicate containing said metal with uncombined phosphoric acid, thereby producing a double phosphate of said alkali metal, and an insoluble residue consisting only of constituents of the original silicate, separating said alkali phosphate from the insoluble residue, adding an acid which will replace the phosphoric acid in the salt, thus converting the alkali metal phosphate into the alkali metal salt of the other acid and freeing the phosphoric acid, and crystallizing the alkali metal salt of the added acid from the phosphoric acid and utilizing the recovered phosphoric acid to react upon fresh mineral containing said alkali metal. (Canadian Patent 191,260, FREDERICK D. S. ROBERTSON, Toronto, Ontario; July 1, 1919.)

Book Reviews

THE YEAR BOOK OF THE COKE OVEN MANAGERS' ASSOCIATION. 482 pp., including 169 pp. of tables and miscellaneous general information. London: Benn Bros., Ltd. Printed for private circulation only.

This year book is very creditable to the young British organization whose activities it records, especially considering the extraordinarily difficult conditions existing during the year 1918, which was the second year of the association's existence. The book includes 30 articles on subjects relating to by-product coking, of which 14 articles are printed in full, while the others are reported from various association addresses in the easy and interesting third person style so familiar in British publications. One-third of the book is taken up with mathematical, physical, and chemical tables and miscellaneous general information, even to the extent of income tax notes, all of which will undoubtedly make the volume useful as a handbook to the majority of its subscribers. Probably it is not intended to reproduce this material in subsequent annual issues. Naturally, most of the articles have reference to conditions resulting from the exigencies of the war, and many bear evidence of haste in preparation, which is surely pardonable under the circumstances. The recovery of benzol seems to have occupied the foreground in the meetings and discussions, for eight of the articles deal with various phases of this subject. In the reviewer's opinion, however, none of these articles gives new information of interest to American readers. In particular, the laboratory methods for the determination and testing of the benzols that have been developed on this side of the Atlantic have many points of advantage and superiority over those described in the year book.

Closely allied to the subject of benzol is that of the constituents of coal tar, to which two interesting articles are devoted. The first is a modified translation of Weger's paper "Über Seltene und Reinpräparate aus Steinkohlenteer" (*Zeit. angew. Chem.*, XXII, 1, pp. 338, 391). The translation has been modified and supplemented by Dr. P. S. Spielmann, so that it makes an admirable synopsis of practical information on the coal-tar substances. The second is a short report of a descriptive address by Dr. P. P. Bedson on "Coal-Tar Derivatives," dealing with general economic conditions, with examples of results of research in this industry. Ammonia recovery was the subject of discussion at three or four meetings, one of the most interesting addresses being made by Mr. E. Kilburn Scott on the "Manufacture of Ammonium Nitrate in Coke Oven Plants." In Mr. Scott's opinion, by-product coke plants can readily and profitably undertake the manufacture of nitric acid from a part of the ammonia which they produce and would thereby be enabled to convert all of their ammonia into ammonium nitrate.

Of special interest is the information given at several meetings relating to the use of coke-oven gas in gas engines, an important application with which American engineers have had comparatively little experience. Among other articles of technical interest are several on the subject of refractory materials used in coke-oven construction; a paper on the "Occurrences in the Oven During Carbonization," by D. V. Hollingsworth; a report of Mr. E. M. Meyer's paper on the "Design and Layout of a Modern Coke Plant," and discussions of Boiler Feed Water, Coal Washing, and the Utilization of Low-Grade Fuels.

Of statistical importance is a complete list of by-product coke-oven plants in Great Britain, giving the name and address of each concern, the number and type of ovens, the by-products recovered, and the name of the coke-oven manager.

It is interesting and gratifying to note that the two principal themes that run consistently through the majority of addresses and discussions are appreciation of the importance of the chemist in the industry and consideration

of ways and means for the organized improvement of the industry. In all discussions of the second theme, the first is recognized as being closely related and fundamentally necessary. The Coke Oven Managers' Association is to be congratulated on the broad-minded and far-seeing attitude which is maintained in considering the general problems of the industry.

F. W. SPERR, JR.

Personal

Mr. HAROLD ADAMS, who was formerly production manager of the New York plant of E. R. Squibb & Sons, has resigned to accept a position with the research laboratory of the U. S. Rubber Co., Waterbury, Conn.

Col. F. J. M. AULD, of the British Army, has resigned his position as professor of chemistry at Reading and is now with the research laboratory of the Anglo-Persian Oil Co., 15 St. Phillips Road, Surbiton, Surrey, England. Col. Auld will be remembered by many of the men in the service who came in contact with him while he was chief of the British Chemical Warfare Mission at Washington, for his pleasing personality and his thorough knowledge of matters pertaining to gas warfare. Col. Auld has recently received the Distinguished Service Medal from Gen. Pershing and was awarded the Order of the British Empire and a Brevet by his own government. The company with which he has now associated himself is building a large refinery in Wales.

Dr. EDWARD BARTOW, formerly Lieutenant-Colonel in the Sanitary Corps, connected with the Water Supply Service of the A. E. F., has resumed his former work as chief of the Illinois Water Survey Division.

Mr. BERRY V. BUSH, formerly head of the chemistry department at Friends Central School, Philadelphia, has been appointed research chemist in the organic research laboratory of the Eastman Kodak Co., Rochester, N. Y.

Mr. H. E. CLEAVES is now with the Charleston Chemical Co., Charleston, W. Va., as chief chemist, having left the Metal & Thermit Corp., Jersey City, N. J.

Mr. H. W. CURRY recently resigned from the Ozark Smelting & Mining Co., Coffeyville, Kan., to accept a position in the oxide department of the American Zinc, Lead & Smelting Co., Hillsboro, Ill.

Dr. HARRY A. CURTIS, formerly in the Federal Nitrogen Research Laboratory, is now on the chemical faculty of the Northwestern University, Evanston, Ill.

Mr. ELLIOTT E. GEISINGER, formerly of the Pfaunder Co., is now connected with the Firestone Tire & Rubber Co., Akron, Ohio, as industrial engineer.

Mr. H. D. GIBBS has resigned as chemist in charge of the color laboratory of the U. S. Bureau of Chemistry to accept a research position with E. I. duPont de Nemours & Co., at its Jackson Laboratories, Wilmington, Del.

Mr. CHESTER G. GILBERT has resigned from the Smithsonian Institution to accept a position on the staff of Arthur D. Little, Inc., of Cambridge, Mass., which has opened a Washington office in the Munsey Building, with Mr. Gilbert in charge.

Dr. EDWARD S. JOHNSON, formerly with the Solvay Process Co., has accepted the position of director of manufacture and chief chemist of the U. S. Color & Chemical Co., with main office in Boston and plant at Ashland, Mass.

Mr. ROY G. KNICKERBOCKER has accepted the position of superintendent of erection and operation of a new smelter and refinery for the Messina Development Co. of Transvaal, South Africa.

Mr. J. A. LECLERC has resigned as chemist-in-charge of the laboratory of plant chemistry of the Bureau of Chemistry, Washington, D. C., to accept a position with the Miner-Hillard Milling Co., Wilkes-Barre, Pa.

Mr. J. R. LORENZ, formerly in the research laboratory of William F. Mosser Co., Chicago, Ill., is now with the Northeastern Leather Co., Salem, Mass., as tanning chemist.

Mr. W. H. MACMILLAN has resigned as chief chemist of the Remington Typewriter Co., Ilion, N. Y., to accept a position in the metallurgical laboratory of the Halcomb Steel Co., Syracuse, N. Y.

Mr. CHARLES A. MANN has been appointed professor of industrial chemistry, School of Chemistry, University of Minnesota, Minneapolis, Minn.

Prof. C. H. MATHEWSON has been elected professor of metallurgy and metallography in the Sheffield Scientific School of Yale University.

Dr. E. MILLER, associate in chemistry at Johns Hopkins University, has resigned to take a position with the duPont Powder Co.

Mr. NORVILLE C. PERVIER, recently discharged from the U. S. Army, has returned to his former position as chief chemist of the Standard Chemical Company, Inc., Des Moines, Iowa.

Dr. A. PIRELLI has been elected president of an Italian Society of Chemical Industry which has been organized at Milan.

Dr. ARTHUR B. RAY, recently Captain in the Chemical Warfare Service, has joined the staff of the research laboratories of the National Carbon Co., Inc., Cleveland, Ohio.

Mr. R. C. SHUEY has resigned as assistant superintendent of Armour Soap Works to go into the engineering department of the Redmanol Chemical Products Co., Chicago, Ill.

Mr. ALFRED H. WHITE, formerly Lieutenant-Colonel and chief of the research section of the Nitrate Division of the Ordnance Department, has returned to his former position as professor of chemical engineering at the University of Michigan, but is retaining connection with the nitrogen fixation work as consulting engineer of the Ordnance Department.

Current Market Reports

The Non-Ferrous Metal Market

New York, Dec. 29:—The copper market has gained both in strength and in activity during the last week. Tin is practically the same in price. A steady demand for lead has stiffened the price.

	Cents Per Lb.
Copper, electrolytic.....	18 75
Aluminum, 98 to 99 per cent.....	33.00
Antimony, wholesale lots.....	9 75
Nickel, ordinary.....	42.00
Nickel, electrolytic.....	45.00
Tin, Straits, spot.....	53.25
Lead, New York, spot.....	7 50
Lead, E. St. Louis, spot.....	7 20
Silver..... (Dollars per oz.)	1.33 1/2

FINISHED METAL PRODUCTS

	Warehouse Prices Cents Per Lb.
Copper sheets, hot rolled.....	28.50
Copper sheets, cold rolled (over 14 oz.).....	30.50
Copper bottoms.....	37.00
Copper rods.....	29.50
High brass wire and sheets.....	25.50
High brass rods.....	24.24
Low brass wire and sheets.....	28.25
Low brass rods.....	28.25
Brazed brass tubing.....	37.25
Brazed bronze tubing.....	42.00
Seamless copper tubing.....	32.00
Seamless bronze tubing.....	36.00
Seamless brass tubing.....	30.50

SCRAP METALS

	Cents Per Lb.
Aluminum, cast scrap.....	22 1/2 - 23 1/2
Aluminum, sheet scrap.....	21 1/2 - 22 1/2
Aluminum clippings.....	24 1/2 - 26
Copper, heavy machinery comp.....	14 1/2 - 14 1/2
Copper, heavy and wire.....	13 1/2 - 14
Copper, light and bottoms.....	12 1/2 - 12 1/2
Copper, heavy cut and crucible.....	15 1/2 - 16
Brass, heavy.....	7 1/2 - 8 1/2
Brass, casting.....	10 1/2 - 10 1/2
Brass, light.....	5 1/2 - 6 1/2
No. 1 clean brass turnings.....	8 1/2 - 8 1/2
No. 1 comp. turnings.....	11 1/2 - 12
Tea lead.....	4 50 - 4 60
Lead, heavy.....	5 76 - 5 87
Zinc, scrap.....	4 1/2 - 4 1/2

The Iron and Steel Market

Coal shortage is still a factor in restricting steel mill operations, but not to the extent of keeping operations below the rate obtaining just before the coal shortage developed. Rather the difficulty is that some of the capacity which the practical disappearance of the iron and steel strike would permit of being operated is held idle. On the whole there is considerably more capacity in operation now than when the coal shortage became a factor early in December. Coke shortage is as much of a factor in restricting operation of blast-furnaces as coal shortage is in the case of steel mills. For illustration, both the Bellaire and Mingo works of the Carnegie Steel Co., in the Wheeling district, had been idle since Sept. 22 on account of the iron and steel strike, which held on longer in the Wheeling district than anywhere else, and last week the Mingo works started but the Bellaire works remained down from lack of coke, a condition that will probably be remedied this week.

COKE OUTPUT INCREASING

The by-product ovens have been steadily increasing their coke output as coal supplies increased, through getting back to normal coking time. The Carnegie Steel Co. is now about to put in operation two new batteries of ovens at the Clairton plant, 64 ovens each, recently completed. The original plant of ten batteries, 640 ovens, was completed and put in operation before the end of last year. The plant eventually is to comprise 20 batteries, the original plan having been to build ten batteries at the outset and the remaining ten at a considerably later time, but during the war two batteries of the last ten were set forward on the program. Apart from the plant of the Pittsburgh Crucible Steel Co., to be completed next summer, there is scarcely any construction of by-product ovens in progress. It is estimated that by-product ovens, in batteries of 50 to 100, would cost about \$45,000 per oven, while the iron and steel industry cannot think of such new construction, apart from the item of cost, as long as it has not sufficient labor to operate in full its various existing facilities.

MARKET QUIET

The pig iron, unfinished steel and finished steel markets have been quiet for a week or ten days, making a sharp contrast with the feverish activity that has prevailed for two months or more. The quietness is the natural and invariable thing for the holiday season, but at the same time it is the unbroken experience of the past that after a "holiday dullness" the markets do not automatically resume their activity, fresh-compelling influences being requisite. Markets are not purely the resultant of statistics or the relation between supplies and requirements, but are distinctly affected by psychological influences. In the case of pig iron, with its advance of \$10 to \$12 a ton since last June, chiefly in the past few weeks, it may even be found that there was something more than normal psychology, possibly a little of "mob psychology" or the psychology of the crowd. The past week is the first for two months or more in which no noteworthy advances in pig iron have occurred. Declines in the near future, however, are probably out of the question, for all furnaces are sold up for several months ahead and would have no occasion to cut prices even if demand were extremely light. In the eastern Pennsylvania and Buffalo districts there was considerable buying by speculative interests and there is always a possibility of speculators endeavoring to unload at unsuitable times.

PREMIUMS FOR STEEL

While the finished steel markets have been much quieter in the past week, greater delivery premiums have been paid in a number of instances. A fortnight ago plates for early delivery were in general at about 2.75c., higher prices being paid only on very small lots, but two or three lots in tonnages running into four figures have lately been sold at 3c. The Carnegie Steel Co. has again bid 2.50c. on plates for the Navy Department, the lot now in negotiation being 10,000 tons. The March 21 or "stabilized" price is 2.65c., and the Steel Corporation does not in any instance

ask more. Some large independents are quoting 2.75c. even for late deliveries, while prices above that are for very early deliveries only. Steel bars in small lots have been bringing as high as 3c., the regular price being 2.35c., but some relatively conservative interests are on a 2.50c. basis, despite the adherence of the Steel Corporation and some independents to the 2.35c. price. Sheets, both black and galvanized, have been done at \$10 premium for first quarter.

The Chemical Market

New York, December 26, 1919.

A perspective of the current year's market shows great activity among users of chemicals and a mighty effort on the part of the producer to meet this increased demand of a post-war period. Among the primary causes of the present high scale of prices are the unsettled labor conditions, scarcity of raw materials and a lack of adequate transportation facilities.

The past week has been a period of resting before the take-off for the new year, all branches being quiet. *Sal-ammoniac* remains firm at 12½-14c. per lb., car lots, and 13½-15c. in less than car lots. There is some English sal-ammoniac on the market at 11c. per lb., but it is the opinion of some that England will place an embargo on the exporting of this item to the United States owing to a scarcity of ammonia liquor. *Caustic soda* has jumped from \$3.80 to \$4.10-\$4.35 per cwt., while *formaldehyde* is scarce at 20-37c. per lb. *Sodium bichromate* is easier with a new low mark of 22c., against 25c. per lb. of last week. Quotations on *alcohol* are unobtainable. There is a considerable supply of ethyl and denatured, but the prices being paid by the patent medicine men are prohibitive and drive off any other likely buyers. Further difficulties arise from the uncertainty as to the stand the Government will take regarding denatured alcohol. Some former distillers have put up large denaturing plants.

Dimethylaniline in the coal-tar products is active at 88-90c. per lb. compared with 60-92c. of the previous report. Japan at present is a heavy buyer of this item. *Aniline oil* has had considerable inquiry and is easier than last week, the low price dropping from 35c. to 34½c. per lb., drums included, while *aniline salts* is unobtainable, though quoted at 43-45c. The demand on *benzol*, pure water white, at 27-31c. per gal., *toluol* in tanks 28c. per gal., and *naphthalene* continues heavy, with prices firm.

Naval stores are firm, with a reported firmer Southern market; prices remain unaltered. The lack of cables from English and Indian markets due to the holiday season celebration leaves the same prices standing from last week in the *crude rubber* market. *Vegetable oils* have been dull caused by the buyers balking at the present scale of prices.

In the miscellaneous materials *barytes*, domestic white floated, is especially active at \$35-\$40 per ton, with the entire production filling domestic demand. *Fuller's earth*, domestic and imported, is unobtainable at present, with the nominal quotation of \$25-\$35 on the former and \$35-\$45 per ton on the latter still holding. *Domestic chalk*, extra light, claimed to be lighter than the imported extra light, is quoted at 5-5½c. per lb., while the light is being sold at 4½-5c.

Ferro-alloys are firm and quiet. Among the ores and semi-finished products *tungsten* has had some movement, owing to those who have this item stocked clearing their books; prices remain about the same.

Domestic producers of *ferromanganese*, after making fairly large sales at their advanced price of \$120, delivered, have now advanced to \$130, on which basis the market is quiet. English is now quoted at the advanced price of \$125, c.i.f., but in the circumstances there would be little demand at that figure. *Spiegeleisen* is quoted at \$40, furnace, for spot and \$41 to \$42 for futures.

Electric-furnace *ferrosilicon* is quiet at recently advanced prices, makers quoting \$90 for 50 per cent and \$140 to \$150 for 75 per cent, delivered Pittsburgh, valley and Cleveland districts. Blast-furnace *ferrosilicon* is quiet, with the following prices ruling on bessemer ferrosilicon: 10 per cent, \$59.50; 11 per cent, \$62.80; 12 per cent, \$66.10, f.o.b. Jackson, Ohio.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	30 20	\$0.60 - \$0.65
Acetone.....cwt.	2.50 - 52.25	3.00 - 3.25

Paraffine waxes, refined, 128-130 m.p.....	lb.	.09	.10
Paraffine waxes, refined, 133-135 m.p.....	lb.	.11	.12
Paraffine waxes, refined, 135-137 m.p.....	lb.	.11	.13
Stearic acid, single pressed.....	lb.	.23	.26
Stearic acid, double pressed.....	lb.	.28	.29
Stearic acid, triple pressed.....	lb.	.32	.33

NOTE—Quotations on paraffine waxes are nominal

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal.	\$1.25	
Pine oil, pure, dist. dist.....	gal.	1.00	
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal.	.47	
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal.	.35	
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal.	.65	
Pine tar, ref., oil, sp. gr. 1.080-1.060.....	gal.	.38	
Turpentine, crude, sp. gr. 0.900-0.970.....	gal.	1.00	
Hardwood oil, f.o.b. Mich., sp. gr. 0.940-0.990.....	gal.	.70	
Pine wood creosote, ref.....	gal.	.51	

Naval Stores

The following prices are f.o.b. New York, for carload lots.

Rosin B-D, bbl.....	280 lb.	\$17.00	\$17.50
Rosin F-I.....	280 lb.	17.55	18.25
Rosin K-N.....	280 lb.	19.75	23.00
Rosin W. G. V. W.....	280 lb.	22.50	24.25
Wood rosin, bbl.....	280 lb.	17.00	17.50
Spirits of turpentine.....	gal.	1.65	1.66
Wood turpentine, steam dist.....	gal.	1.63	
Wood turpentine, dist. dist.....	gal.	1.50	
Pine tar pitch, bbl.....	200 lb.	8.25	8.50
Tar, kiln burned, bbl. (500 lb.).....	bbl.	14.50	14.90
Retort tar, bbl.....	280 lb.	15.00	15.25
Rosin, first run, bbl.....	gal.	91	
Rosin oil, second run.....	gal.	.28	.93
Rosin oil, third run.....	gal.	.95	1.12
Rosin oil, fourth run.....	gal.	1.05	1.15

Solvents

73-76 deg., steel bbls. (85 lb.).....	gal.	\$0.33	
70-72 deg., steel bbls. (85 lb.).....	gal.	.30	
70-72 deg., steel bbls. (85 lb.).....	gal.	.30	
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	.23	

Crude Rubber

Para—Upriver fine.....	lb.	\$0.53	\$0.54
Upriver coarse.....	lb.	.35	.35
Upriver caeco ball.....	lb.	.34	.35
Plantation—First latex, clean.....	lb.	.51	
Ribbed smoked sheet.....	lb.	.48	
Brown crepe, thin, clean.....	lb.	.46	.47
Amber crepe No. 1.....	lb.	.49	

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b. New York.

Castor oil, No. 3, in bbls.....	lb.	\$0.18	\$0.19
Castor oil, AA, in bbls.....	lb.	.21	.22
China wood oil, in bbls.....	lb.	.22	.23
Cocoon oil, Ceylon grade, in bbls.....	lb.	.17	.18
Cocoon oil, Ceylon grade, in bbls.....	lb.	.19	.20
Corn oil, crude, in bbls.....	lb.	.19	.21
Cottonseed oil, crude (f.o.b. mill).....	lb.	.18	.19
Cottonseed oil, summer yellow.....	lb.	.22	.22
Cottonseed oil, winter yellow.....	lb.	.22	.22
Lined oil, raw, car lots.....	gal.	1.80	1.87
Lined oil, raw, tank cars.....	gal.	1.80	1.83
Lined oil, boiled, car lots.....	gal.	1.80	1.87
Olve oil, commercial.....	gal.	2.50	2.80
Palm, Lagos.....	lb.	.17	.17
Palm, bright red.....	lb.	.16	.17
Palm, Niger.....	lb.	.17	.17
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.23	.23
Peanut oil, refined, in bbls.....	lb.	.26	.28
Rapeseed oil, refined in bbls.....	gal.	1.45	1.60
Rapeseed oil, brown, in bbls.....	gal.	1.60	
Soya bean oil (Machurian) in bbls, N. Y.....	lb.	.17	.22
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.15	.15

FISH

Winter pressed Menhaden.....	gal.	\$1.20	
White bleached Menhaden.....	gal.	1.25	
White bleached Menhaden.....	gal.	1.26	
Blown Menhaden.....	gal.	1.26	

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated.....	ton	\$35.00	\$40.00
Barytes, of color.....	ton	20.00	25.00
Blaine flux, dry.....	lb.	04	04
Blaine flux, pulp.....	lb.	30.00	50.00

Yellow pine, 3/4 to 8/8, 20 ft. and under at Chicago.....	M.	48.00	
Yellow pine, 3/4 to 8/8, 20 ft. and under at St. Louis.....	M.	40.00	
Roofing, tar felt (14 lb. per 100 sq ft.).....	ton	20.00	
Roofing, tar pitch (in 400-lb. bbl.) carlots.....	ton	21.80	
Roofing, asphalt pitch, carlots.....	ton	34.80	
Roofing, asphalt felt, carlots.....	ton	65.00	
Roofing, slate-surfaced, per roll of 108 sq ft. carlots.....	ton	2.25	
Roofing, slate-surfaced shingles, 100 sq ft. carlots.....	gal.	6.00	
Lined oil, raw in barrels.....	gal.	1.90	
Lined oil, 5 gal. cans.....	lb.	11	
Red lead, dry, 100 lb. keg.....	lb.	1.43	
Red lead, in oil, 100 lb. keg.....	lb.	1.13	
Red lead, dry, 5 lb. cans.....	lb.	1.13	
Red lead, in oil, 5 lb. cans.....	lb.	1.13	
White lead, dry and in oil, 100 lb. keg.....	lb.	1.13	
White lead, dry and in oil, 25 and 50 lb. kegs.....	lb.	1.13	
White lead, dry and in oil, 5 lb. cans.....	lb.	1.13	

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45	
Angles, 3 to 6-in, 3-in, thick.....	100 lb.	2.45	
Tees, 3-in. and larger.....	100 lb.	2.45	
Plates.....	100 lb.	2.66	
Rivets, structural, 1-in. and larger.....	100 lb.	4.20	
Rivets, conchoidal for boilers, 1-in. and larger.....	100 lb.	4.30	
Sheets, No. 28 black.....	100 lb.	4.35	
Sheets, No. 10 blue annealed.....	100 lb.	5.25	
Sheets, No. 28 galvanized.....	100 lb.	5.70	

For painted corrugated sheets, add 10c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

EMERYVILLE (Oakland P. O.)—W. J. Miller, architect, 417 Market St., San Francisco, will soon receive bids for the construction of a 2-story factory, for the American Rubber Co., Emeryville. Estimated cost, \$100,000.

LOS BANOS—The City Trustees have purchased the plant of the West San Joaquin Water Co. and plan to move same here and install tank, tower and filter in same.

Colorado

DENVER—The state plans to install an oil shale laboratory in the University of Colorado. Estimated cost, \$20,000.

Connecticut

NAUGATUCK—Lockwood, Green & Co., architects, 101 Park Ave., New York City, will receive bids for the construction of a factory for the Naugatuck Chemical Co., c/o architects. Estimated cost, \$70,000.

NEW BRITAIN—Landers, Frary & Clark (manufacturers of electric hardware), Commercial and Center Sts., have awarded the contract for the construction of 4 buildings, including a 4 story, 40 x 68 ft. tempering building, on South Stanley St., to the Torrington Building Co., 197 Water St., Torrington. Estimated cost, \$49,000.

Illinois

ALTON—The Illinois Glass Co. has purchased a plot at North Crawford and Wrightwood Aves., Chicago, and plans to build a new plant on same. Estimated cost, \$250,000.

CHICAGO—The Channel Chemical Co., 58 East Washington St., has awarded the contract for the construction of a 4 story, 150 x 300-ft. factory on Western Ave. and West 45th St., to Davidson & Weiss, 53 West Jackson Blvd. Estimated cost, \$450,000.

WHEATON—The city will soon receive bids for the construction of a sewage disposal plant, including filter beds. Estimated cost, \$200,673. L. J. Ruddock, city engr.

Indiana

INDIANAPOLIS — The Van Briggel Chemical Co., 429 North Capitol Ave., plans to construct a 3-story, 160 x 200-ft. display and factory building at 16th St. and Capitol Ave. Estimated cost, \$125,000. Charles E. Bacon, Merchants Bank Bldg., architect.

New Jersey

NEW BRUNSWICK—The city plans to issue \$13,000 bonds for the installation of additional units at the filtration plant.

TRENTON—The International Glassoform Co., 664 East State St., plans to build an oil plant here. Estimated cost, \$50,000. L. E. Warren, Brokaw Bldg., New York City, interested.

Maryland

BALTIMORE—The American Sugar Refining Co., 117 Wall St., New York City, is having plans prepared for the construction of a sugar refining plant on Locust Pl. harbor front. Estimated cost, \$3,000,000. Ralph Stubbs, general manager.

BALTIMORE—Louis Miller, 5 Lloyd St., will receive bids about Jan. 15 for the construction of a 2-story, 45 x 50-ft. dairy and cold storage building at 5-7-9 Lloyd St. Estimated cost, \$50,000. G. R. Callis, Melvin Ave., Catonsville, architect.

CURTIS BAY—(Baltimore P. O.)—The Curtis Bay Copper & Iron Works will build a 1-story, 75 x 230-ft. addition to the structural iron and copper works on plant on Beach St. Estimated cost, \$100,000.

Michigan

NORTHVILLE—The Detroit Board of Health, 232 Antoine St., Detroit, plans to construct a 2-story, 28 x 36-ft. laboratory 2 miles north of here, in connection with the group of buildings to be constructed at the proposed Detroit Municipal Tuberculosis Sanitarium. Complete laboratory equipment will be installed in same. Stratton & Snyder, 1103 Union Trust Bldg., Detroit, architects.

Minnesota

DULUTH—The Minnesota Steel Co. has had plans prepared for the construction of an extension to the blast-furnace plant here. Project includes 3 additional blast-furnaces, 14 open-hearth furnaces and a unit of 16 soaking-pit furnaces. Estimated cost, \$10,000,000.

Ohio

BARBERTON—The Portage Rubber Co. is having plans prepared for the construction of an office building and power plant in the western section of the city. Estimated cost, \$200,000.

CLEVELAND—Edward Statutek, commissioner of purchases, city hall, received bids for the construction of a sewage disposal plant in the easterly section of the city, from the American Construction Co., Marion Bldg., \$258,957; McHugh Bros., West 37th St., \$338,730; Masters-Mullen Construction Co., Electric Bldg., \$400,486. Plans include a laboratory and a 140 x 142-ft. screen grit chamber building.

DAYTON—The Vaucler Fertilizer Co., Irwin St., has awarded the contract for the construction of a 2-story, 110 x 130-ft. rubber factory to the Bellfontaine Steel Co., Bellfontaine. Estimated cost, \$100,000.

NEWARK—The Parish Rubber Co. has awarded the contract for the construction of a 2-story, 110 x 130-ft. rubber factory to the Bellfontaine Steel Co., Bellfontaine. Estimated cost, \$100,000.

Pennsylvania

WILKES-BARRE—J. Linn Johnson, Ross St., plans to construct a 2-story, 50 x 125-ft. machine and welding shop at Ross and Gildersleeve Sts. Estimated cost, \$45,000.

Rhode Island

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9, and 10.

THE AMERICAN INSTITUTE OF MINING AND METALLURGY will hold its spring meeting in New York, Feb. 16-19.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

THE MINING AND METALLURGICAL SOCIETY OF AMERICA will hold a meeting in New York Jan. 13.

Industrial Notes

THE SPEARE CHEMICAL PRODUCTS CO., New York, has opened a branch office in Boston, Mass., at 27 School St., under the personal supervision of Mr. E. Goldstein.

THE OLIVER CONTINUOUS FILTER CO. announces the removal of its New York office to the Acollan Bldg. The rapidly increasing business of the company requires much larger space than it was able to obtain at the old quarters. Mr. Gordon Walker is in charge.

THE CROCKER-WHEELER CO., of Amper, N. J., has just inaugurated a plan of training for its foremen and other factory supervisors which is of considerable interest. A group of 62 men has been formed to pursue a three months' course in modern production methods, which comprises the study of specially prepared text materials, the solution of problems relating to the units, and the discussion of this material at six bi-weekly meetings held after hours in the plant. These meetings will provide an opportunity to bring home the application of the work to the special problems of Crocker-Wheeler Co. production. At each meeting a lecture will be delivered by an experienced production man and the lectures will be followed by a round-table discussion. Included in the group, besides foremen, are the superintendent and an assistant superintendent, which insures that the meetings will be highly resultful to the members of the class. The subjects to be studied are: How to promote team work in the shop; handling men in a way to increase production and promote harmony; how production should be organized; efficient purchasing, scheduling, routing, repairing, etc.; keeping down the overhead by stricter cost keeping; major problems of management. The course is under the direction of the Business Training Corporation of New York City, which supplies the study material and the class instruction.

MR. EARL E. EBY, sales manager of the Hyatt Roller Bearing Co., has been appointed to the board of directors of HYATT, LTD., a new company formed to market the Hyatt bearings in Europe. Mr. Eby will devote his entire time to this work in New York City. He had previously been formerly Chicago district manager, has been promoted to the position of sales manager to fill the vacancy formed by Mr. Eby's new duties.
